VOLUME II—TABLE OF CONTENTS

Appendix A	List of Preparers
Appendix B	EIA Team Curricula Vitae
Appendix C	Water Quality Modeling Report
Appendix D	Participatory Fishing Study Final Report January 2019–March 2020
Appendix E	Ambient Onshore Air Quality Monitoring Report
Appendix F	Onshore and Offshore Meteorological Data
Appendix G	Emissions Inventory and Air Quality Modeling Report
Appendix H	Underwater Sound Modeling Report
Appendix I	Recent Environmental Baseline Survey Reports
Appendix J	IUCN-Listed Coastal and Marine Species Known From Guyana with Red List Status Classified as Data Deficient
Appendix K	Marine Bird Study Report: Marine Bird Survey 2017-2020
Appendix L	Coastal Bird Survey Report: Coastal Bird Study 2017-2020
Appendix M	Nearshore and Offshore Fisheries Study Summary
Appendix N	ExxonMobil Multi AUV Geophysical Survey Protected Species Observer Summary Report
Appendix O	Coastal Sensitivity Maps
Appendix P	Flora and Fauna of Shell Beach
Appendix Q	Final Analysis Report—2018-2020 Shell Beach Turtle Tracking Project
Appendix R	List of Marine Fishes in Guyana
Appendix S	Enhanced Coastal Sensitivity Mapping—Ecosystem Services Final Reports
Appendix T	Traffic Impact Assessment
Appendix U	Stakeholder Comments
Appendix V	Commitment Register
Appendix W	Meeting Records—EIA Development

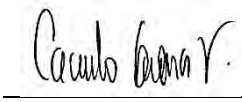
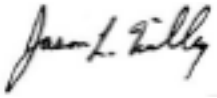
LIST OF PREPARERS

Todd Hall, ERM: Program Lead

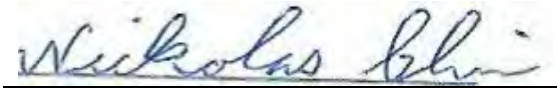
Steve Koster, ERM: Partner-in-Charge



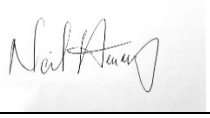
Camilo Gaona, ERM: Partner



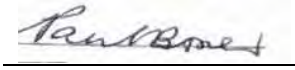
Jason Willey, ERM: Project Manager



Nickolas Chin, ERM: Health and Safety Lead

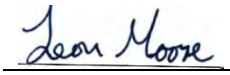


Neil Henry, ERM: Consultant Coordinator



Paul Bonar, CEMCO: Consultant Coordinator

Elford Liverpool, University of Guyana: Consultant Coordinator / Zoologist



Leon Moore, Leon Moore Nature Experience: Consultant Coordinator / Zoologist

Noam Raffel, ERM: GIS Specialist

Haimwant Persaud, CEMCO: GIS Specialist

Amberly Moon, ERM: Biodiversity Specialist

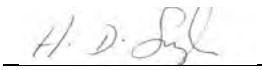
Mark Ram, University of Guyana: Biodiversity Specialist

Indranee Roopsind, Leon Moore Nature Experience: Biodiversity Specialist

Leanna Kalicharan, University of Guyana: Marine Science Specialist

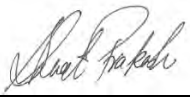
Mark Irvine, ERM: Physical Oceanographic Specialist

Catriona Munro, ERM: Marine Scientist / Biological Oceanographic Specialist



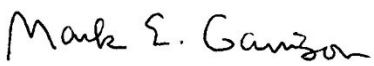
Hemwantie Singh, CEMCO: Marine Water Quality Specialist

Michael Lowe, CEMCO: Marine Water Quality Specialist

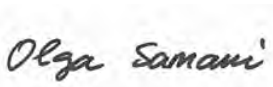


Shwet Prakash, ERM: Water Quality Specialist

Jacob Guise, ERM: Hydrodynamic Modeling Specialist



Mark Garrison, ERM: Air Quality Modeling Specialist



Olga Samani, ERM: Air Quality Modeling Specialist

Surya Ramaswamy, ERM: Air Quality Modeling Specialist

Anna Sundby, ERM: Socioeconomic Resources / Stakeholder Engagement Specialist

Candice Ramessar, ERM: Socioeconomic Resources / Stakeholder Engagement Specialist

Ashanta Osborne, CEMCO: Social Specialist

Amanda Sahai-Alli, CEMCO: Social Specialist

APPENDIX B

EIA Team Curricula Vitae

Todd H. Hall, PE

Guyana Program Lead, Partner-in-Charge

Todd has over 25 years of broad experience in environmental consulting, focusing on environmental, social and health impact assessment, management plan development, multi-media permitting, site planning and licensing, remediation, and risk assessment. He has prepared environmental, social, and health impact assessments and management plans for dozens of exploration and development projects in North America, South America, Asia/Pacific, Africa, and the Middle East. Todd has worked with ExxonMobil for his entire career, from his first project involving a remedial investigation of a legacy ExxonMobil property, and he has led ERM's programs for ExxonMobil at multiple downstream facilities, legacy sites, LNG regasification facilities, and upstream exploration and development projects worldwide. He has been a part of ERM's support to EEPGL in Guyana since 2017, and has been the Program Lead for ERM's support to EEPGL since early 2018.

Experience: Over 25 years in oil and gas, petrochemical, mining, and power

Education

- M.E. Civil (Environmental) Engineering, Texas A&M University, College Station, TX, 1995
- B.S. Civil Engineering, Texas A&M University, College Station, TX, 1994

Professional Affiliations and Registrations

- Registered Professional Engineer, Texas
- International Association for Impact Assessment
- Society of Petroleum Engineers

Languages

- English, native speaker

Fields of Competence

- Environmental, social, and health impact assessment
- Environmental, social, and health management plan development
- International Best Practice (EP, IFC PS, etc.)
- National Environmental Policy Act (NEPA)
- Environmental planning, siting, and licensing for U.S. and international energy projects
- Multi-media environmental permitting
- Environmental engineering design
- Site investigation and remediation
- Risk assessment (human and ecological)
- Regulatory compliance assessment

Key Industry Sectors

- Oil and Gas
- Petrochemical
- Power
- Mining

Key Projects

Environmental Impact Assessments
Directed Environmental Impact Assessments (EIAs), inclusive of socioeconomic and community health resources, and associated data collection and stakeholder engagement process for the proposed Liza Phase 2 Development Project and the Payara Development Project, both offshore Guyana. Data collection included completion of onshore and marine traffic studies, onshore and offshore ambient air quality monitoring, and surveys of marine fish, marine benthos, coastal birds, seabirds, marine turtles, and ecosystem services in the Project Area of Influence.

Environmental Management Plans
Directed Environmental Management Plans for several multi-well exploration campaigns offshore Guyana.

Environmental Impact Assessment
Served as senior technical reviewer for an Environmental Impact Assessment for the Liza Phase 1 Development Project offshore Guyana.

Environmental, Social, and Health Impact Assessment
Led preparation of a bankable Environmental, Social, and Health Impact Assessment for a proposed gold mine in Colombia, working from a separate Spanish-language National EIA.

Environmental Planning, Impact Assessment and Regulatory Strategy Implementation
Directed and led the project for a proposed greenfield petroleum refinery and integrated power plant in South Dakota. Completed an environmental critical issues analysis; prepared a permitting strategy; completed an ecological reconnaissance, wetland delineation, and cultural resources intensive survey; prepared for and participated in public open houses and public zoning board hearings; prepared draft re-zoning language; completed a socioeconomic baseline study and economic impact analysis; and prepared a human health risk assessment regarding forecasted air emissions from the facility.

Regulatory Approvals Process
Supported the process for proposed LNG export terminal in western British Columbia. Prepared EA summary documentation to aid in dissemination of EA findings and proposed mitigations to internal and external stakeholders and interested parties. Provided advice related to project design alternatives with respect to air quality regulatory ramifications. Assisted with GHG management strategy including support for lifecycle analysis and development of recommendations for use in influencing and managing emerging GHG regulations applicable to the BC LNG industry.

Environmental Licensing
Directed the assessment and licensing for the Golden Pass LNG Terminal and associated Golden Pass Pipeline system in East Texas and Northwest Louisiana. Developed permitting and development strategies, prepared Environmental Resource Reports to be submitted with separate Natural Gas Act Section 3(a) and Section 7(c) applications to FERC, and prepared related federal, state, and local environmental permit applications. Coordinated ancillary studies to support the application (e.g., traffic study, bird strike monitoring). Directed field activities in support of licensing, including extensive field wetland delineation and archaeological surveys.

Socio-economic Baseline Study
Completed a socio-economic baseline study for a series of Texas counties and Louisiana parishes along the U.S. Gulf Coast. Collected an extensive socio-economic data set and created a methodology to ‘rate’ a number of socio-economic aspects of each county/parish with respect to its development needs and the degree to which each was expected to support future oil and gas development growth in the region.

Environmental Management Plan Development
Developed an environmental management plan, a waste management plan, a regulatory compliance plan, and an environmental monitoring plan for the Golden Pass LNG regasification terminal and pipeline's transition from development/construction to operations. Developed a detailed Compliance Register identifying all environmental, health and safety regulations applicable to terminal and pipeline operations, the basis for applicability, and the specific actionable requirements stemming from regulations.

Environmental Impact Assessment
Managed an Environmental Impact Assessment for the proposed Ras Tanura Refinery Expansion Project in the Kingdom of Saudi Arabia, including completion of extensive CALPUFF air dispersion modeling.

Environmental Impact Assessment
Managed an Environmental Impact Assessment for the proposed Wasit Gas Plant Project in the Kingdom of Saudi Arabia, including completion of extensive CALPUFF air dispersion modeling.

Phase I HSEIA
Directed the HSEIA under ADNOC's Code of Practices for the Integrated Gas Development – Project Habshan Platforms located in the Umm Shaif Field offshore Abu Dhabi.

Air Dispersion Modeling
Managed air dispersion modeling in support of the Saudi Kayan Petrochemical Complex development project in Jubail Industrial City, Saudi Arabia.

Environmental Assessment
Prepared the environmental component of a Public Utility Commission application to construct a transmission line from east Texas into the Houston area. Completed intensive environmental field surveys and prepared an Environmental Assessment (EA) triggered from the project crossing Federal lands.

Environmental and Socioeconomic Feasibility Study
Conducted an environmental and socioeconomic feasibility study for the development of a liquefaction facility in the Caribbean Islands. Rated and ranked several candidate sites based on environmental and social impact criteria.

Environmental, Social and Health Impact Assessment (ESHIA)
Directed the ESHIA for the proposed Congo River Crossing Canyon Project offshore Angola.

Environmental and Social Impact Assessment
Directed the assessment for a 370km segment of a proposed crude oil pipeline in Colombia, including preparing a gap analysis between local licensing requirements and the requirements that would apply under an international financing approach. Collected primary data, identified and communicated planned project details with stakeholder groups including protected communities, and completed a topographic and geotechnical survey of the pipeline segment route.

Social and Health Impact Assessment
Conducted technical review for an assessment of unconventional production operations across a >100,000 acre shale gas formation in the Eagle Ford formation.

Hazard Studies
Completed three separate studies to assess the risk associated with operation of flares on gas production platforms offshore Equatorial Guinea.

Environmental and Social Due Diligence
Completion an assessment for the proposed 'farm-in' acquisition of unconventional natural gas production operations in Eastern Louisiana. Completed a Risk Analysis transaction including interviews with the firm's management and other personnel at the firm's headquarters, and site visits to representative facilities to present summary of findings, including an

assessment of the priority of findings based on a risk categorization structured to inform decision-making.

Philosophies and Plans
Directed the development of environmental control design philosophy, oil and hazardous materials spill response philosophy, environmental management plan, environmental monitoring plan, waste management plan, and regulatory compliance plan for a component of the Barzan gas development project offshore Qatar.

Waste Management Plan
Prepared the plan for oil and gas operations in the Western Desert of Egypt.

Environmental/Regulatory Framework
Directed the assessment for the area of a proposed exploration and production effort offshore Barbados.

Technical Review
Served as Senior Technical Reviewer for a desktop environmental, regulatory, and social review and ecological resource assessment for an exploration and production area of interest in Colombia.

Environmental Impact Assessment
Directed the assessment for a proposed offshore natural gas pipeline in Angola and for three separate Supplemental EIAs for offshore oil and gas developments offshore Angola.

Environmental Impact Assessments
Directed several assessments for proposed exploratory drilling projects offshore Angola. Completed social baseline data gathering, oil spill modeling, cuttings discharge modeling, and regulatory licensing support.

Environmental Impact Assessment
Directed an assessment for proposed production platform expansions offshore Angola.

Air Quality Modeling Study
Conducted the study for a proposed floating production, storage, and offloading facilities offshore Angola. Used the Offshore Coastal Dispersion Model to predict transport of air pollutant concentrations from offshore sources to onshore receptors.

ESHIA/ESAP
Directed and led an Environmental, Social and Health Impact Assessment (ESHIA) and associated Environmental and Social Action Plan (ESAP) prepared in accordance with international best practice (EBRD and ADB) standards for the Ukhaa Khudag (UHG) Project, including a coal mine, coal-fired power generation facilities, a groundwater abstraction field, and other supporting facilities in southern Mongolia. Conducted extensive social and environmental baseline data gathering, air dispersion modeling, and noise modeling, and supported stakeholder engagement and consultation activities. Prepared Railway Construction Ecological Best Practices and Resettlement Best Practices white papers, and completed environmental and social action plan monitoring and evaluation.

Environmental and Social Impact Assessment
Prepared a preliminary ESIA for a major copper/gold mine in Alaska. Provided strategic direction relative to the ESIA approach and conducted technical reviews of project deliverables.

Environmental and Regulatory Management Plan
Developed an internal plan detailing the division of environmental and regulatory responsibilities and interfaces between exploration, geo-operations, and drilling business units within a major oil and gas company.

Environmental and Social Due Diligence
Directed the baseline characterization and conducted a due diligence exercise for a prospective farm-in of unconventional gas production operations in east Texas and northwest Louisiana. Assessed potential

environmental and social risks associated with increased production in the area.

Environmental Assessment
Directed a production well re-entry assessment to support development of oil and gas resources on property managed by the National Park Service (Big Thicket National Preserve).

Environmental Impact Review and Licensing
Directed a project to support preparation of a Department of Energy (DOE) assessment and associated state-level environmental review documentation for a major solar energy development in the Northeast U.S. Completed a viewshed analysis to assess visual impacts from construction of the project.

Socioeconomic Baseline/Impact Assessment
Directed the assessment supporting a gold mining project in Kazakhstan.

Due Diligence Assessment
Led the assessment for a major petroleum refinery in the U.S. Virgin Islands. Conducted a review of investigation, remediation, and permitting requirements, and status of associated refinery activities.

Hazard Assessment Project
Completed assessment for two proposed natural gas storage caverns in the Southwestern U.S. Developed worst-case failure scenarios and analyzed the expected consequences of the failure.

Environmental Impact Analyses
Acquired drilling licenses and completed the analyses associated with a proposed production well drilling and testing project in northern Brazil.

Air Quality Modeling Study
Conducted the study for proposed floating production, storage, and offloading (FPSO) facilities for a natural gas formation offshore Angola. Used the Offshore Coastal Dispersion Model to predict transport of air pollutant concentrations from offshore sources to onshore receptors.

Sustainability Reporting
Directed the project for a major wind energy development in accordance with Global Reporting Initiative (GRI G3) guidelines. Collected necessary reporting information, prepared an internal reporting handbook, and developed documentation demonstrating methodology used for reporting.

Environmental Licensing
Directed a permitting and impact assessment project in New York for a proposed wind power project. Acquired licensing through the New York State Public Service Commission and prepared an EIS pursuant to the State Environmental Quality Review process. Completed wetland delineation, cultural resource surveys, noise surveys, and visual impact simulations.

Site Screening Studies
Directed over 160 studies for proposed wind power projects in the U.S., each including mapping to identify key resources and land uses at the site, characterization of biological and aquatic resources potentially affected by the development, identification of recorded cultural resources within the site area, evaluation of potential land use related issues (e.g., zoning, visual restrictions, height limitations, designated conservation lands, floodplains, etc.), identification of potential tribal interests, and identification of potential communication, radar, and aviation related issues. Created a permit matrix that identified the federal, state, and local regulatory requirements that would apply to the development, the contact information for the agency responsible for the permit/approval, the requirements of the permit/approval application process, and the anticipated timeline.

Steven J. Koster, P.E.

Partner-in-Charge

Steve Koster has more than 30 years of experience in environmental impact assessment, permitting, and impact mitigation and remediation. Mr. Koster has served as Partner-In-Charge or Project Manager for numerous impact assessment and permitting projects for the oil and gas, energy, mining, transportation, and government sectors within a range of governmental jurisdictions. He has managed multi-disciplinary teams to complete siting studies, environmental baseline studies, impact assessments, permitting, due diligence assessments, and risk assessments.

Experience: 30 years' experience in Oil and Gas, Energy, Mining, Transportation, and Government Sectors.

Key Projects

Keystone XL Pipeline Supplemental EIS. Partner-In-Charge and Project Manager for preparation of the Supplemental Environmental Impact Statement for the proposed Keystone XL Pipeline, an 875-mile long crude oil pipeline that would cross Montana, South Dakota, and Nebraska. Working under the direction of the US Department of State as the Third Party Contractor, ERM prepared a comprehensive analysis of the proposed project and alternatives consistent with the National Environmental Policy Act (NEPA), Endangered Species Act (ESA), and National Historic Preservation Act. Services performed have included reviewing and researching technical data and reports, conducting analyses of environmental and social resources impacts, identifying project alternatives and mitigation measures, and preparing a Draft and Final Supplemental EIS. In addition, approximately 5 million public comments were reviewed, catalogued, and responded to. ERM also assisted the State Department in consultation with various tribes as well as the US Fish and Wildlife Service.

Wolverine Pipeline System Permitting. Partner-In-Charge/Project Manager for obtaining various permits for pipeline repair and maintenance projects in three Midwest states. Completed assessments of wetlands, streams, soils, and biodiversity. Project included permit coordination and negotiation with multiple federal, state, and local regulatory agencies. Managed environmental field staff for permitting compliance monitoring during project construction.

Mariner West Pipeline Permitting Support. Partner-in-Charge for environmental studies and permitting support for the Mariner West ethane pipeline from the Marcellus Shale region in western Pennsylvania through Ohio and Michigan to Sarnia, Ontario. Project involved wetland delineations, wetland mitigation planning support, and cultural resource assessments of planned disturbance areas along the pipeline route.

Marcellus Union Pipeline Fatal Flaw Analysis. Project Manager for Fatal Flaw Analysis of a planned 400-mile NGL pipeline from the Marcellus region in western Pennsylvania through Ohio and Michigan.

Spartan Pipeline EIA and Permitting, 1999-2004. Partner-In-Charge/Project Manager for Environmental Impact Assessment of 63-mile long pipeline in Michigan, including working with MDOT and FHWA for pipeline segments using interstate highway right-of-way. Performed siting studies for alternate routes and completed assessments and evaluated potential impacts on natural and historic cultural resources. Developed mitigation measures to reduce impacts on wetlands, streams, soils, groundwater supplies, air quality, noise, and socioeconomic aspects. Project included permit coordination and negotiation with multiple federal, state, and local regulatory agencies. Provided community and media relations support and expert testimony in multiple contested case hearings and litigation support for Michigan Supreme Court appeal. Managed team of environmental field staff for permitting compliance monitoring during project construction.

Natural Gas Pipeline EIAs and Permitting, various. Partner-In-Charge for Environmental Impact Assessments of multiple natural gas pipelines for landfill gas recovery and natural gas supply to power generating plants, focusing on wetland, stream, soil erosion, and historical resource impacts. Projects included preparation and submittal of permit applications to state and local agencies.

FirstNet Nationwide Broadband System
Programmatic EIS for the Non-Contiguous US. Partner-In-Charge for the first party preparation of the National Telecommunications and Information Administration (NTIA), First Responder Network Authority's (FirstNet) Programmatic EIS for a proposed nationwide, interoperable, public safety broadband network in the non-contiguous region of the US, including Alaska, Hawaii, and five US territories in the Pacific and Caribbean. Responsible for leading the project team conducting the environmental and cultural review and analysis

requirements of NEPA, NHPA, and ESA, consultation with cooperating agencies, and tribal consultation.

USTDA Honeywell Flowergate Preliminary EIA. Project liason and support for preparation of a Preliminary Environmental Impact Assessment for the Sagamu Independent Power Plant Project in Ogun State, Nigeria. In accordance with USTDA requirements, ERM prepared a PEIA in support of a Feasibility Study that identified statutory requirements and global standards on environmental management and sustainability, assessed positive and negative environmental and social effects and made associated recommendations, and presented a roadmap for environment and social impact management for all phases and life cycle of the IPP project.

Organization of American States Baseline Study for Dominica Cruise Ship Port. Project Manager for completion of an environmental baseline study in support of an Environmental Impact Assessment on the Island of Dominica under contract with the Organization of American States in support of a proposed cruise ship port. Project assessed baseline conditions including land and marine resources, cultural resources, and impacts of solid waste and wastewater disposal.

River Reach Boulevard EA. Partner-In-Charge for a NEPA Environmental Assessment for a new FHWA-funded road, working under the direction of the Michigan DOT. Field surveys were completed and impact assessments and mitigation measures were developed for noise, wetlands, and contaminated sites for the transportation corridor that traversed an industrial brownfield area.

Transmission Line EISs. Partner-In-Charge for third-party support and preparation of numerous EISs under a third party contract with the State of Minnesota in coordination with multiple federal and state agencies, including a NEPA EIS for the 68-mile Bemidji-Grand Rapids transmission line through the U.S. Forest Service Chippewa National Forest, a state-level MEPA EIS for the Pleasant Valley-Bryon transmission line, and a MEPA EIS for the Hiawatha transmission line in Minneapolis.

White Pines Wind Energy Facility EIS. Partner-In-Charge for NEPA EIS and permitting for a new 70 MW wind energy facility and transmission line in the U.S. Forest Service Huron-Manistee National Forest. ERM was responsible for supporting the FS throughout the NEPA process, including scoping, resource studies, impacts analysis, alternatives and mitigation evaluation, EIS preparation, and public comment management. ERM developed a stakeholder engagement program and permitting strategy and provided assistance to a local township for wind ordinance development. ERM is responsible for local, state, and federal permitting, including wetlands, streams, stormwater, SHPO, SPCC, special use/zoning, road, and FAA approvals.

Rail Corridor Alternatives Study. Partner-In-Charge and Project Manager of a multi-part confidential rail siting study for a major power utility in the Midwest. The project identified preferred alternatives for delivering coal to six existing and new baseload power plant sites by rail and Great Lakes vessels. Rail corridors were identified, evaluated, and prioritized using technical, environmental, and socioeconomic criteria. Preferred rail transportation corridors were identitied using both new and existing rail lines.

NorthMet Mine (MN) EIS. Senior Technical Lead for Third-Party NEPA EIS for the first proposed sulfide mine, pipeline, and access road in Minnesota. This is a joint federal (USACE, USFS) and state (Minnesota DNR) project that also included the U.S. EPA and multiple tribes as Coordinating Agencies. This project required evaluation of impacts, cumulative effects, and alternatives for development of EIS documents, with a particular focus on issues surrounding potential acid rock drainage and approximately 800 acres of wetlands impacts. Lead for biological and social impact analysis.

Back Forty Mine Baseline Studies, EIA, and Permittiing Support. Partner-In-Charge for completion of an environmental baseline assessment, environmental impact assessment, and support for permitting of a proposed metallic minerals mine, road, and transmission line in the Upper Peninsula of Michigan. Project included assessments of wetlands, threatened and endangered species, cultural resources, hydrology and surface waters, ground water resources and hydrogeology, water quality, and land use. Project involves public presentations to engage and educate community and regulatory stakeholders in aspects and potential impacts of the proposed mine.

Buckeye Wind Energy Facility EIS. Partner-In-Charge for NEPA EIS for Habitat Conservation Plan and Incidental Take Permit for Indiana bat for a proposed wind farm in Ohio. Working under the direction of the USFWS and in cooperation with the wind developer, ERM prepared the EIS under a precedent-setting permitting process pursuant to the federal Endangered Species Act. Project included scoping evaluation, HCP review, alternatives evaluation, and impacts and mitigation analysis for draft and final EIS preparation.

Municipal Power Plant Stakeholder Engagement. Partner-In-Charge for a stakeholder engagement program for proposed expansion of a municipal coal-fired power plant in Michigan. Internal and external stakeholders for this controversial project were identified, mapped, and interviewed to educate stakeholders and identify interests. The mapping results were used as input to the project decision-making process and a comprehensive communications program was developed.

Camilo Gaona

Partner

Camilo is a Partner in ERM and is the Lead for the operation of ERM Guyana since 2018. Between 2016 and 2018 was the Team Lead for Environmental Impact Assessments in ERM Korea and was responsible for undertaking International ESIAs, Environmental monitoring and audit (EM&A) as well as Environmental and Social Due Diligence in alignment with International Standards, either for commercial banks or ECAs. He is focused on Environmental and Social Impact Assessment Projects in a number of sectors including Oil & Gas and Power sector. He has been working on projects in several locations and countries as South Korea, Myanmar, Philippines, South Africa, Botswana, Mongolia, Turkmenistan, Colombia, Nicaragua, Dominican Republic and recently Guyana, developing International ESIA according to IFS-Ps and OECD Guidelines and following local regulations for each one of the countries, giving him a wider experience in environmental and social permitting processes.. He has conducted several ESDD in different in different countries in Asia, Africa, Middle East and Latin America in alignment with Equator Principles (EP), OECD, among others.

Experience: 12 years' experience in oil & gas, and power sectors

Email: camilo.gaona@erm.com

LinkedIn: www.linkedin.com/in/camilo-gaona-6745866b

Education

- Environmental Engineer, La Salle university, Colombia, 2008
- IFC Performance Standards, Managing Environmental and Social Performance course, 2014

Professional Affiliations and Registrations

- Engineering Association of Colombia -COPNIA

Languages

- Spanish, native speaker
- English, fluent
- Korean, working knowledge

Fields of Competence

- Environmental and Social Impact Assessment, local and international standards (IFC-PS, OECD, EP)
- Environmental and Social Due Diligence (ESDD), ESAP and monitoring for lenders.
- Environmental and social permitting

Key Industry Sectors

- Oil and gas
- Power
- Infrastructure

Key Projects

Mr .Gaona is familiar with requirements of lenders such as the IFC- PS. He has conducted several ESDD in different in different countries in Asia, Africa, Middle East and Latin America in alignment with Equator Principles (EP), OECD , among others.

Environmental and Social Studies for Kanukuku Block Offshore Guyana . Repsol Guyana. Oil & Gas Sector. 2018- Ongoing, Project Manager
ERM was engaged by Repsol Guyana to conduct and EAMP and ESHIA for the Multiwell Drilling Campaign in Kanuku Block Offshore Guyana. Scope of work also includes the update of the Stakeholders Engagement Plan.

Environmental and Social Impact Studies for Guyana Program . ExxonMobil. Oil & Gas Sector. 2018- Ongoing, Program Master Planner
Planning for different Projects belong to ExxonMobil Guyana Program as Liza Phase 2 and Payara oil fields

Environmental, Social and Technical analysis for a route selection for Gas Pipeline of 150Km length in Dominican Republic. SK E&S. Oil & Gas Sector. 2018- Ongoing, Project Manager
ERM was engaged by SK E&S to and Environmental, Social and Technical analysis to select the most viable route for a gas pipeline of ~150Km length. Scope of work also includes Identification of special crossings as well as diagnosis of roads to be use at construction stage.

Environmental and Social Screening for a Coal Power Plant in Phillipines. SK E&C. Power Sector. 2017, Project Manager
ERM was engaged by SK E&C to conduct an Environmental and Social Screening and a specific mangrove surveys for Coal Power Plant Project in Philippines. 2017

Environmental and Social Assessment and Environmental Legal Review for CCGT Power Plant in Dominican Republic. SK E&S Power Sector. 2017- Ongoing, Project Manager
ERM was engaged by SK E&S to conduct an ESA and Environmental review for a Combined Cycle Gas Turbine Power Plant in Dominican Republic. Scope of work also was a topographic survey and water quality sampling.

International Environmental and Social Impact Assessment for a De-Waxing unit in Turkmenbashi, Turkmenistan in alignment with IFC-PS and OECD Guidelines. O&G. 2017 – On Going, Project Manager
ERM is in charge to conduct an International Environmental and Social Impact Assessment in alignment with IFS-PS and OECD Guidelines for a De-Waxing Unit in Turkmenbashi, Turkmenistan. Project sponsor is a korean company and main finance came from a Korean ECA.

Environmental and social Due Diligence for Coal Power Plant in Botswana, Africa, in alignment with IFC-PS and OECD Guidelines, Power. 2016 – Ongoing. Confidential client, Project Manager
ERM was selected to act as Lender's independent consultant to conduct the ESDD, ESAP and Monitoring for Coal Power Plant (CFPP) in Botswana for a Korean ECA in alignment with IFC-PS and OECD Guidelines.

Environmental and social Due Diligence for Coal Power Plant in South Africa, Africa, in alignment with IFC-PS and OECD Guidelines, Power. 2016 – Ongoing, Project Manager
ERM was selected to act as Lender's independent consultant to conduct the ESDD, ESAP and Monitoring for Coal Power Plant (CFPP) in South Africa for a Korean ECA in alignment with IFC-PS and OECD Guidelines.

Environmental Impact and Social Study for Production Stage in Shwe Offshore Field in Bay of Bengal in Myanmar. POSCO-DAEWOO Corporation. Oil&Gas Sector. 2016-ongoing, Project Manager
ERM is in charge to undertake an Environmental and Social Impact Study for Production Stage in Shew Offshore Field an Offshore block in the as part of the Shwe Development Project in Myanmar.

Environmental and Social Monitoring for a Cracker and PE/PP Plant with IFC Performance Standards, Turkmenistan, Oil & Gas. 2016-ongoing, Project Manager
ERM was commissioned to monitoring the obligations of the EPC consortium for environmental and social aspects as part of an international credit which demands meet the IFC Performance Standards. ERM is the independent consultant for lenders.

Environmental Management Plan for Mining Exploration Activities in Shangalon Project. Myanmar, Mining Sector. 2016, Project Manager
ERM is in charge to undertake the Environmental Management Plan for a Gold-Copper Mining Exploration Activities in Shangalon region in Myanmar.

ESIA for Gran Canal Project in Nicaragua according with international standards. Nicaragua. Infrastructure Sector, 2013- 2015, Project Manager in Country
Preparation of a baseline as part of the elaboration of the ESIA for a Canal project of 270Km length in Nicaragua. Responsible for communications with the government and stakeholders. The project had about 400 people in the field and participation of different offices of ERM.

Environmental Alternatives Study and Environmental Impact Study for a gas pipeline, Colombia, Oil&Gas. 2015-2016, Project Manager
ERM was commissioned to evaluate the alternatives for the construction of a gas pipeline, document to be submitted to the environmental authority. ERM also was commissioned to do the Environmental Impact Study of the gas pipeline.

Environmental Impact and Social Study for an Offshore block, Colombia, Anadarko. Oil&Gas. 2015-2016, Project Manager
ERM was commissioned to undertake an Environmental Impact Study for an Offshore block in the Caribbean of Colombia.

Environmental Management Plan for a Pumping Station of Caño Limon Coveñas Pipeline. Oil & Gas Sector. 2012-2014, Project Manager
Preparation of a decision support document required for Environmental Licensing of a Pumping Station for the main pipeline in Colombia according with Colombian regulation.

Environmental, Social and Sustainable Risk Assessment for a Container Terminal in Cartagena, Colombia. Infrastructure Sector, 2015, Project Manager
Environmental and Social Risk Assessment for Terminal in Cartagena as part of A Due Diligence process, including International Standards (IFC) as one of the matters to assess.

Develop of H&S Management System for an Exploration petroleum Company in Colombia. O&G sector. 2013, Project Manager
HSE Management System was done based in Colombian and international standards for an exploration petroleum company in Colombia.2013- 2014.

Technical Concept to Develop Unconventional Resources in Colombia. Colombia. Oil & Gas Sector. 2013, Project Manager
Working with more than 6 ERM offices spanning 3 regions, ERM developed the Technical Concept for Sustainable Exploration and Production of Unconventional Resources in Colombia.

HSE Compliance Audit, Colombia, Confidential Client, Oil & Gas Sector, 2013, Auditor
We performed the audit of seven petroleum and gas blocks in Magdalena department and Putumayo, preparation of the report according to the scope (internal policies and national regulatory).

Jason Willey

Project Manager

Jason has 20 years of experience in environmental consulting. He focuses on environmental and social impact assessment, due diligence, and permitting. He has extensive experience in northern South America and the Guianas. Jason has been the Program Manager for ERM's support to EEPGL since late 2014. He spent 2007-2008 working in Australia and having led the aquatic resources component of ESIAs and due diligence assessments on every continent except Antarctica, often in remote or frontier regions. He has worked on numerous upstream and midstream oil and gas projects throughout his career, including LNG regasification facilities, pipelines, and upstream exploration and development projects worldwide. Prior to his involvement with EEPGL's activities in Guyana. Jason worked for several years for oil and gas and mining clients in neighboring Suriname.

Experience: 20 years' experience in transportation, mining, oil & gas, power and government sectors

- Power
- Government

Key Projects

Energy Client
Senior aquatic ecologist supporting the completion of a Supplementary Environmental and Social Impact Assessment (ESIA) and associated Management Plans to bring a 900 MW hydropower project planned for the Upper Karnali River in Nepal into compliance with IFC Performance Standards. Working on behalf of the Project Sponsor in coordination with the IFC. Key issues include determining riparian flows required to sustain IUCN listed fishes.

Financial Client
Developed a standard Terms of Reference for hydropower baselines for IFC's Infraventures program. Compiled global best practices for baseline study design, aquatic biodiversity and habitat surveys, and ecosystem services assessment. Presented good practices for fish surveys as part of the Sustainable Hydropower Series of workshops co-sponsored by the IFC and USAID in Nepal.

Government Client
Currently conducting an environmental and social due diligence on the Government of Liberia's rehabilitation of the Mount Coffee Hydroelectric Project, an 80 MW hydropower project Monterserrado County Liberia. Conducting the due diligence on behalf of MCC, which is a major donor to the project. Project involves re-constructing a dam, powerhouse, and reservoir that were destroyed during Liberia's civil war. Major issues include ecoflow and fisheries, resettlement, and community access. Providing strategic advice to MCC and the Liberian Electric Corporation to maximize compliance with the World Bank Environmental Safeguards.

Energy Client
Led a supplemental study of aquatic biological impacts of NSHE's 500 MW run-of-river hydroelectric project proposed on the Batang Toru River in North Sumatra, Indonesia to support lender financing of the project. ERM was engaged to undertake supplemental biodiversity studies, social studies (land acquisition audit, development of a stakeholder engagement plan and gathering of socio-economic baseline data), and an environmental flow study to address identified gaps between the Project's Indonesian Regulatory Approval (AMDAL) and the expectations of the 2012 IFC Performance Standards.

Transportation Client
Led the fisheries and aquatic resource component of the biodiversity field studies for the ESIA for the Nicaragua Grand Canal project, which included a hydropower project on the Agua Zarca River in central Nicaragua. Supervised the daily activities of two groups of fisheries scientists, malacologists, and macro-invertebrate specialists as they surveyed aquatic biodiversity across the Pacific and Atlantic slopes of Nicaragua and Lake Nicaragua. Authored the aquatic biological portion of the ESIA for the project.

Financial Client
Conducted an environmental due diligence on the ESIA for the proposed 48 MW San Bartolo hydropower project proposed on the Rio Negro in Copal Santiago, Ecuador. ERM identified critical gaps in the ESIA analysis and identified seven specific corrective actions that would enhance the ESIA and bring it into compliance with international standards. ERM's EDD report separated these actions into categories according to their priority for implementation, likely effect on construction or operation of the project, and cost to implement.

Power Client
Prepared aquatic resources section of the Preliminary Application Document submitted to FERC for a small (<10 MW) municipal hydropower project on the Grasse River in Massena, MY. Scoped initial aquatic ecological and fisheries studies required for the environmental impact analysis. Supervised riparian habitat mapping surveys and a wetland delineation along approximately 8 miles of the Grasse River. Developed conceptual designs for fish passage facilities designed to pass lake sturgeon (Acipenser fulvescens) and American eel (Anguilla rostrata). Assessed the potential impacts to local traditional fisheries practiced by the Mohawk tribe.

Federal Energy Regulatory Commission (US)
Assessed the effects of the proposed relicensing of Portland General Electric's 173 MW Clackamas River Hydroelectric Project on the Clackamas River in Oregon. Evaluated effects of the hydroelectric facility on fish and aquatic species, including several species of threatened or endangered salmonids. Described PGE's proposed action and incorporated agencies' comments into a comprehensive agency alternative. Authored the Threatened and Endangered Species section of the EIS for the project, which compared the effects of the proposed action and agency alternative on listed salmonids, native fish species, and benthic macroinvertebrates.

Federal Energy Regulatory Commission (US)
Co-authored the fisheries and aquatics resources section of the EIS for relicensing NYPA's 912 MW St. Lawrence-FDR Power Project on the St. Lawrence River in northern New York (US). Assessed of relicensing the hydroelectric project on fish and aquatic species, including several species of threatened or endangered fish, macroinvertebrates, and plankton. Considered effects on rare warm-water habitats created by the project and their role in enhancing fish reproduction in the river. Considered fish passage design and protective measures to avoid loss of fish passing downstream via the spillway and/or the turbines. FERC issued NYPA a 50 year license to operate the project in October 2003.

Mining Client
Preparing an EIA for an aluminum-smelting project in southwest Greenland to include a smelter, marine port, two hydroelectric developments, and electric transmission lines. Issues of concern related to construction of the marine port include potential impacts to near shore marine habitats, marine fisheries, marine mammals, and contamination of the marine environment. Issues of concern related to construction of the hydropower developments include potential ecological impacts of freshwater discharges to near shore marine habitats. Issues of concern related to the transmission lines include potential restriction of access to inshore fishing areas and interference with seabird flight patterns.

Energy Project
Prepared the fisheries and aquatics resources impact assessment as part of the ESHIA for the proposed 60 MW Nam Sane 3 Hydroelectric Project in Ban Phouviang, Xieng Khouang Province, Lao PDR. Conducted field assessments of aquatic habitat, fisheries and aquaculture practices, and general aquatic ecology. Overcame potential safety hazards from unexploded ordinance that prevented in-water surveys by interviewing local and indigenous people concerning fish distributions, migrations, and habitat use, as well as extrapolating from existing fisheries data from elsewhere in the Mekong River Basin. Collated information from various local, governmental, and NGO sources into the environmental baseline, and assessed impacts according to the Department of Energy's guidelines.

Energy Client
Provided general environmental impact assessment and planning services for several petroleum exploration and production facilities around Australia. Prepared EPBC Act (Australia) referrals and environmental management plans for offshore exploration projects. Coordinated oil spill contingency planning and sediment transport modeling to support EIA process for another offshore project in a potentially sensitive marine environment. Managed numerous concurrent modeling tasks to support the EIA process for the project and an ongoing a joint experiment by Woodside and the Australian Institute of Marine Science to determine the effects of accelerated episodic sedimentation on shallow Indo-Pacific reef building corals.

Oil & Gas Client
Managed an EIA for a marine seismic survey in the Great South Basin off the coast of New Zealand's South Island. Key issues include potential impacts on endangered marine mammals, marine fisheries, and seabirds, as well as ecosystem-level effects on sensitive habitats including the Sub-Antarctic island archipelago. Project required collating results of

recent and ongoing scientific research on the effects of vessel noise, seismic noise sources, and near-to mid-field interactions with vessels on rare, threatened, and endangered marine mammals. Impact assessment process included consultation with several key government stakeholders, and resulted in finding of no significant impacts and favorable feedback from NZ regulators.

Hydroelectric Project
Performed the aquatic resources and fisheries impact assessment for the Bui Hydroelectric Project in western Ghana. Key aquatic issues included conversion of riverine habitat to lacustrine habitat, loss of riparian productivity, and migration barriers.

Mining Client, Suriname
Lead aquatic ecologist on a feasibility assessment for a bauxite mine at a greenfield site in central Suriname. Historical investigations documented several species of armored catfish at the site, including at least one species that was potentially endemic to the local watershed immediately surrounding the proposed development site. Subsequently captured two suspected endemic armored catfish species at the site. Other potential ecological receptors of concern included amphibians, terrestrial mammals and birds, and riverine fisheries downstream of the development site. ERM has preliminarily concluded that considerable mitigation was likely to be necessary in order to render the environmental impacts of the proposed project acceptable under international and Suriname standards. Currently planning a detailed aquatic baseline survey at the site to establish the range of the suspected endemic fish at the site.

Power Client
Provided on-call environmental support to project engineers during the design phase of a natural gas pipeline project on Barrow Island off Western Australia. Provided design engineers with strategies intended to streamline the environmental permitting process. Project is a critical downstream component of the Gorgon natural gas development, a $50 billion development project near Karratha.

Hydro Power Project
Authored the aquatic resources and fisheries section of the EIA for the planned 100 MW Kalivac Hydro Power Plant on the Vjose River in Southern Albania. Determined that the project had the potential to fragment populations of resident and migratory fish species, including the several IUCN-listed minnows, two salmonids, and two species of sturgeon. Concluded that the project had the potential to enhance fisheries upstream of the dam due to increased productivity in the impounded reach. Recommended monitoring for indications of barotrauma and/or congregations of migratory fish downstream of the dam, and mitigation of these impacts if required.

International Joint Commission (US and Canada)
Managed a project to evaluate the potential effects of peaking ponding by hydropower interests on the ecology of the St. Mary's River. Consulted with the federal, state, and provincial agency personnel with regulatory responsibility on the river to evaluate the agency's concerns relative to peaking and ponding. Prepared an assessment for the IJC of peaking and ponding's effects on biological resources of concern, including migratory fish, the threatened lake sturgeon (Acipenser brevirostrum), and nuisance species, including the catadromous sea lamprey (Petromyzon marinus).

Virginia Department of Game and Inland Fisheries
Sampled fish communities in several major drainages throughout Virginia (US). Collected historical data and developed a database of historical fish collections throughout the state organized by watershed. Compiled data and prepared reports on watershed health based on recent and historical qualitative and quantitative fish data. Standardized stream data collection procedures in preparation for the eventual development of a statewide fish Index of Biotic Integrity in Virginia.

Recreational Boating Management Plan
Managed an update to the Recreational Boating Management Plan for Deep Creek Lake, an 18-MW

hydropower facility in western Maryland. Projected future use and developed recommendations for managing future recreational use and growth. Characterized use of the lake, involving a stratified random survey of commercial marinas, recreational users, and lakefront residents, and surveys of commercial rental operators, lakefront residents, and recreational boaters. Tracked commercial use in the lake's buffer strip. Determined that commercial use had experienced moderate growth over recent years, and that development could detract from the quality of the recreational resource. Made several recommendations to the DNR and the PRB for managing increased use of the lake.

Confidential Client
Lead biologist on the marine ecology and fisheries component of an Environmental and Social Impact Assessment (ESIA) for a resort planned on New Providence Island, The Bahamas. Verified preliminary marine habitat maps and data provided by the client in the field, and assessed the potential for the proposed project to impact marine resources. Resources of concern included listed marine reptiles, corals, seagrasses, and commercially and recreationally important fish and invertebrates. Conducted high-level consultations with select government agencies to ensure support for the ESIA.

Fisheries and Aquatic Resource
Co-authored the fisheries and aquatics resources section of the EIS for relicensing NYPA's 912 MW St. Lawrence-FDR Power Project on the St. Lawrence River between northern New York (US) and Ontario (Canada). Assessed the potential effects of relicensing the hydroelectric project on fish and aquatic species, including several species of threatened or endangered fish, macroinvertebrates, and plankton. Considered potential effects on rare warm-water habitats created by the project and their role in enhancing fish reproduction in the river. Considered fish passage design and protective measures to avoid loss of fish passing downstream via the spillway and/or the turbines. Reviewed input from Canadian communities affected by the project, including Native American tribes. FERC issued NYPA a 50 year license to operate the project in October 2003.

Nickolas Chin

Health and Safety Lead

Nickolas has 5 years of broad experience in environmental consulting, focusing on environmental, social and health impact assessment, management plan development, environmental compliance, site auditing and risk assessment. With a background in environmental science, his primary focus was on the extractive sector, but has since transitioned into health & safety and environmental services for the energy sector. Experienced in myriad aspects of the local mining and forestry operations, he rapidly developed in health & safety and now focused on the newly burgeoning oil & gas sector. He has prepared environmental, social, and health impact assessments and management plans for multiple local companies, created emergency response plans, health and safety plans and journey management plans to ensure safety is always held paramount. Nickolas is a born and raised Guyanese and has worked and been involved in the local environmental field all his life. He has been a part of ERM's support to EEPGL in Guyana since 2019, and has been the Program H&S Lead for ERM's support to EEPGL since mid 2020.

Experience: 5 Years' experience in the Environmental Field, specifically Extractive Sectors.

Email: nickolas.chin@erm.com

Education

- B.Sc. Environmental Science, University of Guyana, Guyana, 2016

Languages

- English, native speaker

Fields of Competence

- Environmental compliance & operational analysis
- Health & safety best practices
- Activities & logistics coordination

Key Industry Sectors

- Mining
- Forestry
- Health & Safety
- Oil & Gas

Key Projects

EAMP and EIA for a Multi-well Exploration Campaign for O&G Operator in Offshore Guyana (Ongoing)
HSE Lead for the project and works to review the current local situation and update the client whilst in the permitting and planning phase.

ERM COVID 19 Return To Workplace (RTW) (Ongoing)
Created the ERM Guyana Office COVID 19 RTW protocol. Subject Matter Expert on COVID 19 and regular monitoring of the local situation to safeguard company and client interests.

ERM Diversity, Equality & Inclusion (Ongoing)
ERM Global Advisory Group for DE&I global member with regular recommendations and input for improving and promoting the company's DE&I agenda.

Key Projects Prior to Joining ERM

Onshore Technical Services Coordination (2019)
Served as the Technical Services Coordinator for Tiger Rentals Guyana and serviced Esso Exploration and Production Guyana Limited (EEPGL) Marine Logistics Division.

Health, Safety & Environmental Supervision (2018)
Served as the Senior HSE Officer for Environmental Management Consultants (EMC), which is now the local partner to ERM in Guyana.

Occupational Health & Safety Management (2017)
Served as the Occupational Health & Safety Officer for Giftland Group of Companies.

Neil Earle Henry

Consultant Coordinator

Neil is an experienced environmental professional with more than 20 years of experience in the environmental monitoring field both private and public. He previously worked at the Guyana´s EPA and has a good understanding of environmental management issues in Guyana. He has a breadth of experience working across several companies in environmental projects in Guyana. His primary focus was on the mining, forestry and tourism sectors, with experience in infrastructural monitoring. He has assisted in the preparation and review of environmental and social impact assessments and management plans for development projects in Guyana and Suriname. For the last three years Neil has been working with ERM in the Oil and Gas Industry in Guyana exclusively on EEPGL´s projects assisting with the preparation of their ESIAs.

Experience: 20 years' experience in environmental field

Email: Neil.Henry@erm.com

Education

- Graduate Diploma: Climate Change Adaptation, University of the Sunshine Coast, (Australia), August 2008 to March 2009
- Postgraduate Diploma: Integrated Watershed Modeling and Management, International Institute For Geo-Information Science and Earth Observation (ITC), University of Twente (The Netherlands), September 2007 to June 2008.
- B. Sc Environmental Studies, University of Guyana, 2000
- Guyana Mining School

Languages

- English, fluent

Fields of Competence

- Surface and Ground water Monitoring
- Assessing environmental impacts
- Recommending environmental remediation measures
- Prepare and conduct surface and ground water monitoring programs
- Reclamation projects - Gold Mines Limited (Essequibo), Gross Rosbel Gold Mines (Suriname), and Omai Bauxite Mining Inc. (Linden)

Key Projects

Guyana Industrial Minerals Inc. Subsidiary of First Bauxite Corporation - Senior Environmental and Community Relations Advisor (December 2015 to 2017)
Responsibilities include managing all environmental matters relating to the Company's success in achieving financial closure, creating an Environmental Management System using Local and International Standards. Both office and field work.

Troy Resources - Environmental Manager (2014-2015)
Responsibilities include managing all environmental matters relating to the Company's success in its startup of operations, creating an Environmental Management System using Local and International Standards. Both office and field work.

Guyana Industrial Minerals Inc. Subsidiary of First Bauxite Corporation. Environmental and Community Relations Officer (January 2012 to 2014)
Responsibilities include managing all environmental matters relating to the Company's success in achieving financial closure, implementing the Equator Principle Financial Institutions by applying the International Financial Corporation/World Bank Standards. Both office and field work.

Environmental Management Consultants, 60 Area H Ogle, ECD Environmental Inspector (April 2010 to December 2012)
As a team member of the consultant group working on environmental projects; (a) environmental monitoring of the Amaila Falls Hydro Access Road, (b) environmental management plans, (c) environmental monitoring of the Ministry of Public Works and Communications Bridges Rehabilitation Program-Phase 11 Rehabilitation of Lot II – Lot A1 and Lot A2 Structures.

Director on the Guyana Geology and Mines Commission's Board (2006- 2007)
Guyana Environmental Protection Agency, Environmental Officer II (April 2006-2007)
Responsible for all environmental issues that fall under the Mining, Forestry and Tourism sectors. Ensuring that all developers adhere to the Environmental Protection Act No. 11 of 1996 and all Regulations made under the Act.

Omai Gold Mines Ltd, Environmental Officer September (January 2000 to July 2005)
Responsible for coordinating all activities relative to the effective management of environmental activities at Omai Gold Mines Limited. Technical duties include, implementing surface and ground water monitoring programme, implementing the ISO14001 Standards, providing environmental training for Omai's employees. Management duties include supervising subcontractors and consultants working at Omai, representing Omai's interests at meeting with the government regulators as well as professional and industrial association.

Linden Mining Enterprise Ltd, Summer Job (1997,1998,1999)
- Special Projects – Conduct Site Inspections- Progressive Reclamation through the use of native plants in Linden- Water Quality and Erosion Control in Mined-out Areas

Ministry of Agriculture, Livestock Division. (1993-1996)
To provide extension services to the Linden community.

Special Assignments
- Hydro-meteorological Analysis of Lake Naivasha, Kenya and Lake Buurse, The Netherlands
- A Strategic Approach to Solid Waste Disposal in McKenzie, Linden.
- Environmental Inspections of the McKenzie Bauxite Plant and the East Montgomery operations Area
- Stack Dust: Health effects on Lindeners.
- Water Quality in the Northeast Kara Kara Mined-out area.

- The use of indigenous plants as a method of erosion control in mined affected areas.

Reclamation Activities

- Supervise re-vegetation of mine-out areas (approximately 188 hectares).
- Liaise with personnel during sloping, grading, and back filling of mined- out areas.
- Participate in an aquatic monitoring programme at Omai Gold Mines Limited (Aug. 2003).
- Assist and monitor University of Guyana students conducting special projects at Omai Gold Mines Limited.

Environmental Impact Assessment

- Assisted with the accumulation of baseline data for Gross Rosbel's EIA
- Assisted with the accumulation of baseline data for Linmine's EIA
- Trained in ambient dust sampling using the MiniVol dust sampling equipment;
- Trained in ambient noise sampling using the Quest noise level meter

Environmental Audits

- (External Audits) Consultants-Lakefield Research- November, 2000- February, 2003
- SGS ISO 14001 audits
  - Registration Audit- January 2001
  - Maintenance Audit- February 2002
  - Maintenance Audit- March 2003
  - Re-certification Audit- March 2004
  - (Internal Audits)
  - Consultants-G. Amyot- October 2001
  - D. Therrien- January 2003
  - G. Amyot- January 2004

FORM TECH-6

CURRICULUM VITAE (CV)

Name of Expert:	Paul Andrew Bonar, Consultant Coordinator
Date of Birth:	06/11/1946
Country of Citizenship/Residence	Guyana, South America

Education:

Educational Institution	Dates Attended	Degree/Diploma Gained.
University of Guyana	1970-1972	Higher Technical Diploma in Civil Engineering (equiv. to HND (UK).
University of Guyana	1980	Bachelor of Engineering (Civil)
Government Technical Institute	1967-1969	City & Guilds of London Technician's Diploma in Mechanical and Electrical Engineering.

- FIDIC Accredited Certificate in Management of Claims and Resolution of Disputes under MDBs' Harmonised Construction Contract 2010 Edition (2014).
- Fellow of the Guyana Association of Professional Engineers.

Employment record relevant to the assignment:

Period	Employing Organisation and your Title/Position. Contact Information for references	Country	Summary of activities performed relevant to the assignment.
2005 to present	Caribbean Engineering and Management Consultants Inc. (CEMCO); Chief Engineer. Contact: CEMCO (592 226 2758;	Guyana	**Construction Supervision of 3No. large Drainage Pump Stations, Ministry of Agriculture (Feb. 2005 to 2018)**: CEMCO was contracted to supervise and manage three Works contracts (US$5million) using IADB's standard form of contract. The Expert performed the role of Team Leader, supervised team of engineers and technicians and directed the interpretation of the conditions of contract and related contract documentation.
			Marriot International Hotel and Entertainment Center (2015-2017): Following contractual disputes from April 2015, Atlantic Hotel Inc. engaged CEMCO to guide the hotel firm to completing remaining work, remedy a substantial number of defects and to represent the hotel firm in managing

			all disputes, using the in-place FIDIC Design-Build form of Contract. The Expert was the lead representative for CEMCO, made all assessments and issued recommendations.
			BNTF Programmes (Various; 2005 to 2018): Under its Basic Needs Trust Fund Programme, the Caribbean Development Bank engaged CEMCO under several infrastructure projects (water, education, health, municipal markets, etc.) Basic Needs Trust Fund Programme to provide design and supervision services. As Chief Engineer, the Expert supervised development of design and the procurement and supervision of Contractors using CDB's procurement procedures and the FIDIC Multilateral Development Bank Harmonised Edition of Conditions of Contract for Construction for Building and Engineering Works designed by the Employer.
			GPL IDP (US$42M; 2010 to 2014): The national power utility, Guyana Power & Light Inc. engaged CEMCO to supervise a design-build contract for the engineering, procurement and construction of approx.100km of 69kV transmission lines, 10No. 69kV/13.8kV Substations with a SCADA Automation System, valued at US$40 million. The Expert represented the Engineer under FIDIC Design-Built contract format and in the role of Resident Engineer, managed the procurement of the installations, resolved contract issues and valued the work as it progressed.
			IADB T1090 - GWI Guyana Water Supply & Sanitation Infrastructure Project (US$28M; 2014): Development of Design Criteria and Preparation of Tender Documents for procurement of Contractors for a) Design-Build of 3 Water Treatment Plants (WTPs), Upgrade of 3 WTPs and approx. 50km of new reticulation as well as b) Employer's (Consultant) full-scale design for the Upgrade of existing 18km of reticulation in the city of Georgetown, Guyana (Est. US$30M). The Expert performed the function of Procurement Specialist, reviewed technical scope of works, performed desktop research on various applicable forms of contract to suit specific scope including design build for

			water treatment works and employer-designed for reticulation work. Recommended and finalised forms of bidding structures for two types of contracts. Prepared bidding documents to complement technical designs and specifications. Finally modified to suit Client's specific choices. Worked separately and with Consultancy team.
			GoG Amaila Falls Hydropower Project – 49KM Road Contract (US$8.5M; 2013): CEMCO was engaged by the National Industrial and Commercial Investment Limited (NICIL) on behalf of the Ministry of Public Works and Transport, Government of Guyana to develop a Contract for design, procurement and construction of 49km of new access road, being the final section of the hinterland route to the proposed Amaila Falls Hydropower Project. The Expert in the role of Contract Specialist: a) Utilised the FIDIC Silver Book (Design Build) Form of Contract, developed Special Conditions of Contract and related Contract Addenda including Payment Schedule, Form of Agreement, Performance Security, Advance Payment Bonds, etc. b) Reviewed Employer's Requirements to ensure compatibility with Contract Forms; advised adjustments. c) Assisted the Client with contract negotiation and finalisation of Contract with selected firm, China Railway First Group (Guyana) Inc.
			GoG Georgetown Marriott International Hotel and Entertainment Complex (US$52M; 2011): CEMCO was engaged by the National Industrial and Commercial Investment Limited (NICIL) on behalf of Atlantic Hotels Inc. to develop a Contract for design, procurement and construction of a 197 room international hotel and entertainment complex in Georgetown, Guyana. The Expert in the role of Contract Specialist: a) Utilised the FIDIC Design Build Form of Contract, developed Special Conditions of Contract and related Contract Addenda

			including Payment Schedule, Form of Agreement, Performance Security, Advance Payment Bonds, etc. b) Used the FIDIC Design Build Form of Contract, developed Special Conditions of Contract and related Contract Addenda including Payment Schedule, Form of Agreement, Performance Security, Advance Payment Bonds, etc. c) Following selection of the preferred bidder, assisted the Client with contract negotiation and finalisation of Contract.
			GoG Berbice River Bridge Project (US$40M; 2005-2009): CEMCO was engaged by the National Industrial and Commercial Investment Limited (NICIL) on behalf of emerging Berbice Bridge Co. to conclude Contract negotiations and to supervise the Contractor for the design and construction of a 1.6km long pontoon floating bridge at the estuary of the Berbice River, Guyana, with a 70m wide retractable span; using suction embedded anchor systems to restrain the 39 pontoons, pre-fabricated galvanised steel sections, riding surface of calcined bauxite embedded in polymer and approaches at both landing ends. The Expert performed the roles Contract Specialist/Resident Engineer/Deputy Project Manager: a) As Contract Specialist, assisted in the negotiation of the final form of FIDIC design build contract including special conditions of contract, bonds and payment schedule. b) As Resident Engineer and Deputy Project Manager, used the contract particulars to aid the control of the contract processes and the delivery of the bridge.
1996 to 2004	Guyana Water Authority (GWI); Project Manager Engineer. Contact: o - GWI, Guyana - Jailal (592 225 0471).	Guyana	**Water Supply Technical Assistance and Rehabilitation Project (Est. US$60M; 1996 2004)**: The Government of Guyana, through the Guyana Water Authority, the national water utility, undertook the procurement of Works for the improvement of water supply systems along the coastal region of Guyana where 90% of the population resides. Funded

			by several multilateral Agencies including World Bank, European Union, DFID, European Investment Bank, Caribbean Development Bank, Japanese Govt., and Govt. of Guyana. Includes rehabilitation of approx. 100 well pump stations and 5 water treatment plants, construction of 4 new water treatment plants; improvement and extension of pipe reticulation in all project areas. Procurement of laboratory facilities, etc. The Expert was engaged by the World Bank to manage the entire project; with the assistance of international specialist, develop procurement documentation including forms of contract for all aspects of the project, management of the tender processes, and management of both construction firms and engineering supervision services to ensure project deliverables are achieved wrt time, quality and cost. Perusal of all forms of contract and editing to suit local requirements.

Membership in Professional Associations and Publications:

Fellow of the Guyana Association of Professional Engineers.

Language Skills (indicate only languages in which you can work):

Adequacy for the Assignment:

Task No.	Ref. to ToR	Detailed Task assigned to the Procurement Specialist	Reference to Prior Work/Assignments that Best illustrate Capability to handle the Assigned Tasks.
1.	All aspects,	a) Review Terms of Reference and	All work references in

	including 1.03 (assistance to GoG in managing the procurement of Contractors)	finalise with Consultant's Team Leader any issues relating to the CDB's procurement procedures and the specific suitability of the FIDIC Multilateral Development Bank Harmonised Edition of Conditions of Contract for Construction for Building and Engineering Works designed by the Employer. b) Agree on the approximate construction time lines each of the eight interventions and the packaging of these interventions into eight or less individual contracts. c) Review and discuss the general content of the document for prequalification of Contractors.	including the Expert's extensive general experience in the planning and timely execution of works.
2.	3.06 (e)	a) Prepare document for pre-qualification of Contracting Firms using the CDB i) User's Guide for Prequalification Document for Procurement of Works and ii) Prequalification Document for Procurement of Works. b) Finalise document after review with Team and Client.	Tasks undertaken for BNTF during 2005 to present.
3.	3.06 (b)	Following finalisation of Task 1 and tentative agreement on Task 2, prepare the bidding documents for each bidding package, Part I - Bidding Procedures and Part 3 – Conditions of Contract and Forms. Part 2 would await inputs from the design engineers and other specialists. The form of Contract would be in keeping with CDB procedures, namely FIDIC Multilateral Development Bank Harmonised Edition of Conditions of Contract for Construction for Building and Engineering Works designed by the Employer.	Tasks undertaken in all of the aforementioned bid and contract preparations.
4.	3.06 (b)	Finalise all documents and publish as required after approval by the Team Leader and concurrence by the Client. If may be required to issue pre-qualification document before the end of Phase II – Detailed Design.	All work references in including the Expert's extensive general experience in the planning and timely execution of works.

Expert's contact information: (pbonar@cemcoguyana.com, phone: 226 2758)

Certification:

I, the undersigned, certify that to the best of my knowledge and belief, this CV correctly describes myself, my qualifications, and my experience, and I am available to undertake the assignment in case of an award. I understand that any misstatement or misrepresentation described herein may lead to my disqualification or dismissal by the Client, and/or sanctions by the Bank.

Education

DOCTOR OF PHILOSOPHY (Ph.D) BIODIVERSITY CONSERVATION –STUDENT
Thesis topic: Mining impacts, mercury and food web ecology in fishes of the Middle Mazaruni River Drainage, Guyana
UNIVERSITY OF GUYANA AND (COL: SAM HOUSTON STATE UNIVERSITY, U.S.A.
SEPT 2015-PRESENT

MASTERS OF SCIENCE (MSC) IN FOREST BIOLOGY)
SEPT2010- NOV 2013
UNIVERSITY OF GUYANA AND (COL: ROM AND UOFT, CANADA) GEORGETOWN, GUYANA

TURKEYEN CAMPUS
Thesis: **Impacts of environmental degradation on fish assemblage structure in the Upper Mazaruni River Basin, with description of their community structure and habitat requirement, Guyana, South America**
Advisors; Dr. Hernan Lopez, University of Toronto and Royal Ontario Museum, Canada and Dr. A. Ansari, Mr. P. Da Silva; Faculty of Natural Sciences, University of Guyana

INT'L DIPLOMA PROJECT MANAGEMENT **APRIL–AUGUST 2010**
EDEX U.K. AND UNITED KINGDOM
ROYAL ACADEMY GEORGETOWN, GUYANA

INTERNATIONAL CERTIFICATE IN MUSEUM STUDIES **2008**
COMMONWEALTH ASSOCIATION OF MUSEUM (CAM) CANADA

TRAINED IN TAXIDERMY AND MUSEUM CONSERVATION **DEC 2008 - 2009**
GUYANA NATIONAL MUSEUM GEORGETOWN, GUYANA
INSTITUTE OF ECOLOGY AND SYSTEMATICS (CUBA) & MINISTRY OF CULTURE, GUYANA)
HAVANA, CUBA
Advisor; Mr. Marco Olcha, Institute of Ecology and Systematics, Cuba

BACHELOR OF SCIENCE DEGREE (BSC BIOLOGY) **2001 - 2005**
UNIVERSITY OF GUYANA GEORGETOWN, GUYANA
Major: Biology *Minor:*Chemistry
Activities: Member of UG football club (Natural sciences).
Major Research: **The effects of *momordica charantia* (karela) and *apium graveolens***

(celery) on high blood pressure and blood glucose levels in laboratory rats.
Supervised by; Dr. Emanuel Cummings, Faculty of Health sciences

Certificate in Laboratory Techniques **May- Sept. 2005**
GOVERNMENT ANALYST FOOD AND DRUGS DEPARTMENT KINGSTON GEORGETOWN
MINISTRY OF HEALTH BRICKDAM, GEPRGETOWN

Guyana Zoo Education Volunteer Certificate April- **Aug 2004**
GUYANA NATIOINAL ZOO GEORGETOWN, GUYANA

Certificate in Ornithological (bird) field and taxidermy Techniques **Aug 2004**
Smithsonian Institute WASHINGTON DC, U.S.A.
Centre for the Studies of Biological Diversity UNIVERSITY OF GUYANA.

EIGTH (8) CARIBBEAN EXAMINATION COUNCIL (CXC) - GENERAL PROFICIENCY LEVEL
1996 – 2001.
ST. JOHN'S COLLEGE. GEORGETOWN, GUYANA
ENG/A-111, MATHS-111, SOC.STUDIES-111, HISTORY-11, BIO-11, AGRI-SCI-11, INTE-SCI-11 AND ENG/B 1V
Awards: Second best graduating student for the year **2001.**
Best graduating student in **Biology, Agriculture Science** and **History** for the year **2001**

Research Projects/ Papers/Publications

Shark identification using DNA barcoding from fin clips in Guyana (in Darft) Oct, 2016

Scoping study for sharks and rays from artisanal fisheries in Guyana (Funded by WWF-Guianas) 2015-2016

Impacts of environmental degradation on fish assemblage structure in the Upper Mazaruni River Basin, with description of their community structure and habitat requirement, Guyana, South America. E. Liverpool (in Draft and review) 2016

Mind the (information) gap: the importance of exploration and discovery for assessing conservation priorities for freshwater fish.
Alofs, Liverpool, Lopez, Bernard & Taphorn **(**Pub) Aug 2013

New species of *Cichlid* (Teleostei: Cichlidae) *Krobia aff. potaroensis* from the upper Mazaruni River drainage, Guyana. Steele, Liverpool and Lopez (Pub) Jul 2013

New species of *Lebiasina* (Ostariophysi: Characiformes: Lebiasinidae) from the upper Mazaruni River drainage, Guyana. reira, Taphorn, Liverpool *etal* 2012 (pub) Jan 2013

Phylogenetic diagnosis and expanded description of the genus *Mazarunia* Kullander, 1990 (Teleostei: Cichlidae) from the upper Mazaruni River, Guyana, with description of two new species
Lopez, Taphorn and Liverpool Pub 2012

Taxidermy and Museum conservation Manuals composed, developed and edited with Cuban Museum Specialist: Mr. Marco Olcha and Elford Liverpool **December 2008-2009**

Formula for Taxidermy Works, Guide to taxidermy classes, Procedure manual for crustacean taxidermy (crab), Procedure manual for crustacean taxidermy (lobster), Procedure Manual for Liquids Collections, Procedure Manual for Preparation of Chelonian (turtles), Procedure Manual for Preparation of Fishes with scale, Procedure Manual for the Preparation of Bats, Procedure manual for preparation of bird for study skins, Procedure manual for reptiles, Procedure manual for Snakes, Procedure manual for taxidermy of amphibians, Procedure Manual for the preparation of Skeletons, Procedure manual for preparation of small mammals, Procedure manual for taxidermy of mammal heads for trophy, Recommendations for the capturing and mounting insects and butterfly,

Recommendations for the conservation of the zoological collections and Recommendations for the Preparation of Shells and Snails, A proposal on the general recommendations for the Guyana National Museum developed by Mr. Marco Olcha and Elford Liverpool.

The effects of *momordica charantia* (karela) and *apium graveolens* (celery) on high blood pressure and blood glucose levels in laboratory rats; this research was done in the aim of suitable alternatives to treat High blood pressure and Diabetes in Guyana using natural plant
extracts that are found locally in Guyana**.** **Elford Liverpool Sept. 2005** (unpublished)

Completion of a **tour guide booklet** for the Guyana National Museum.
It is based on Guyana's Natural history (faunal biodiversity and the taxidermy specimen) and social history collections displayed at the National Museum. (MCYS printed)

Employment/Research Experience

Head, Department of Biology
Management of Biology Department on day to Day basis, Budgeting, Development and Implementation of Programmes, Human Resource management, policy decisions, Examinations.

July 2017-
July2019

Lead Researcher/Consultant NAPPI Reservoir Fisheries Project CI-Guyana
Biodiversity and Fisheries survey for NAPPI Reservoir project, Nappi Village, Region 9, 2019. Fisheries and other biodiversity assessment of reservoir including water quality data collection, Checklist/inventory of species, characterization of habitats. Conservation International Funded Project.
February- April 2019

Museum conservation Workshops
Chief Instructor and Trainer for two workshop programs for Ministry of Culture, Government of Guyana on Museum conservation and preservation techniques for natural history collections (flora and fauna) and ethnographic artifacts (basketry, craft etc) from Amerindians in Guyana. Twenty (20) persons were trained in theoretical and practical work in Care for Museum
collections**.** **Novermber-December, 2017**

Co-Lead Researcher: Length Frequency Data Guyana-Suriname-WWF Guianas
Development of protocols for length frequency and size at maturity data for commercially important fish species in Guyana and Suriname. Coordination of data collection for Guyana in collaboration with Tomas Williams in Suriname.
August 2017-2018

Museum conservation Workshops
Chief Instructor and Trainer for two workshop programs for Ministry of Culture, Government of Guyana on Museum conservation and preservation techniques for natural history collections (flora and fauna) and ethnographic artifacts (basketry, craft etc) from Amerindians in Guyana. Twenty (20) persons were trained in theoretical and practical work in Care for Museum
collections**.** **Novermber-December, 2016**

Public Presentation: Sharks and Rays
Scoping study for sharks and rays from artisanal fisheries in Guyana at Muray House Georgetwon, (Funded by WWF-Guianas)
November, 2016

Executive Board Member Wildlife Scientific Authority (CITES) Board
Aid in policy decision making for wildlife studies and related issues in Guyana. Monitoring of permits and wildlife related activities in Guyana. **January 2016-present**

Lead Researcher: Dry season Field Survey and data collection on mining impacts on fishes and food web ecology in mid and lower Mazaruni River, region 7 Guyana.
Project in collaboration with IDB-UGSTSP, ROM Canada, Auburn University USA, WWF-

Guyana, GGMC and EPA Guyana. **July- August, 2016**

Temp. Marine Officer: WWF-Guiana
Temporary staff with responsibility for the marine programs in Guyana. Assist with completion for two sets of proposals (SRJS & EU MPA/MSP) and WWF country programs and budgets. Interacted with stakeholder's including Department of Fisheries, Protected Areas Commission, CI-Guyana, FAO and other NGOs for successful participation and implementation of projects related to the Marine Sector.

May-July, 2016

Lead Researcher: Wet season Field Survey and data collection on mining impacts on fishes and food web ecology in mid and lower Mazaruni River, region 7 Guyana.
Project in collaboration with IDB-UGSTSP, ROM Canada, Auburn University USA, WWF-Guyana, GGMC and EPA Guyana. **March- April 6, 2016**

Identification and survey of Sting Rays on the Coast of Guyana
Survey of Sting Ray diversity on the Coast of Guyana using various gear types (with Mohini Sooklall. **Sept-2015-May, 2016**

Estuarine Fish Diversity project
Seasonal variations in diversity of Fishes in the estuarine of the Demerara and atlantic coast Guyana. (with Ajuba Clarke) **Sept-2015-May, 2016**

WWF-Guyana: Survey of Sharks and Rays landed at fisheries sites on the coast of Guyana
General survey including questionnaire instrument, shark and ray identification, collection of socio-economic data and morphometric data and DNA samples from sites in Region 2, 3, 4, 5 and 6.

June-July, 2015

Awardee: IDB-University of Guyana Science and Technology Support grant (33,000 USD)
Impacts of Mining on Fish Community Structure and trophic levels (diet) using stable isotopes in the Lower Mazaruni River basin, Guyana. Donald Taphorn, Royal Ontario Museum Canada, Hernan Lopez-Fernandez, Royal Onatrio Museum Canada and University of Toronto; Jon Armbruster, Auburn University USA, Abdullah Ansari, University of Guyana; World Wildlife Funds (WWF)-Guyana, EPA-Guyana, GGMC-Guyana. **June 2015- Present**

Lead Researcher-Guyana Gold Fields
Assessment of Stream Health and mercury analysis of macro-invertebrates and fishes of the Cuyuni River, Guyana. Guyana Gold Fields **June-July 2015**

Co-Lead Researcher-Estuarine and Marine fisheries Survey
Survey of Freshwater, Estuarine, and Marine fishes of Demerara and coast of Guyana; In collaboration with CSBD, ROM and University of Toronto, Canada. **March-April, 2015**

Researcher: WWF-Guyana and Global Wildlife Conservaion

Assessment of stream health and fishes of the Konawaruk and Mazaruni rivers and Exploration of Upper Berbice river. Sampling of fishes and marco-invertebrates using various methods and techniques and recording water quality data. Collection of tissue samples for Mercury analysis from fishes in all locals. Assessment of habitat and technical report writing and submissions.

Sept 1-30, 2014

Amaila Falls Consultancy: Assistant Research Consultant: WWF and IDB

Lead by Prof. Donald Taphorn, this exercise embarked on collection of specimens for newly described *Characiduim amaila* fish species from the Amaila falls and ecological habitat data to better understand their population genetic structure and habitat requirement needs, to assess other potential habitats that will reduce any impacts of dam construction on species population of this fish species, and to provide strong recommendations to mitigate any threats from such projects. This is to assist with the implementation and construction of the Amaila hydroelectric dam on the Kuribrong river, Guyan**.** **March to April 2014**

Scientific Officer/Lecturer

University of Guyana, Faculty of Natural Sciences, Department of Biology; teaching Taxonomy, ecology, biostatistics, biodiversity surveying techniques to Biology Undergraduate students. Aslo works on verification of specimens for export from field researches in Guyana at the CSBD with collaborations with the EPA and CITES Deparments. Supervision of Undergrad final year projects.

September 2013-present

Amaila Falls Consultancy SITHE Global: Assitant Research Consultant

This excercise embarked on collection of specimens for newly described *Characiduim* and *Lebiasina* fish species from the Amaila falls and ecological habitat data to better understand their population genetic structure and habitat requirement needs. This is to assist with the implementation of the next phase for the construction of the Amaila hydroelectric dam on the Kuribrong river**.**

April-May 2013

Teaching assistant (TAs) for **Ornithology** and **Herpetology** studies at **Camp Seywao, Linden Highway** to University biology students. This involved trapping using various methods, collecting, Taxonomy: identifying species and environmental impact such as food resources, human impact etc. and methods in preservation of specimen. **March 2013**

Project Manager and Coordinator:

The preparation and launching of a Museum Mobile and School Loan Programme for the

Guyana National Museum and schools around Guyana; The programme involved taking Museum exhibits to schools and uses them as teaching aids in classrooms with work sheets. It also aims to promote museum awareness and preserve our cultural heritage in Guyana.

February 2013

Government Chief Museum Rep.
Cross-Border Network of Amazonian Museums Conference and meeting win Suriname, French Guiana and Brazil to assess the situation of Museums across the region and to establish bi-lateral and concrete agreements with these neighbouring countries. Presentation was done on Museums and our cultural programmes in Guyana to the audience. **December 2012**

Teaching assistant (TA): for **Mammology** and **Ichthyology** studies at **Chikabaru- Region 10** to University biology students. This involved trapping using various methods, collecting, identifying species and environmental impact such as food resources, human impact etc. and preservation of museum specimens (fishes and small mammals). **November 2012**

Chief Instructor and coordinator for The Children's Taxidermy Camp 2012: at the Guyana National Museum. It involved lessons and practical work on wildlife biodiversity, environmental problems and taxidermy preparation of simple specimens along with roles of Museums. Organizations involved are Iwokrama, University of Guyana, Centre for the Study of Biodiversity, and the Environmental Protection Agency. **July- August, 2012**

Project Planner: Annual Immigration exhibition at the Guyana National Museum
The objectives of the exhibition are: to highlight the Cultural Impacts of Indentured Immigrants since their arrival to Guyana, to develop a program of activities that would promote Cultural Diversity in Guyana using the Indentureship Experience and to commemorate the arrivals of the Chinese, Portuguese, East Indian and African Immigrants to Guyana. **May 2012**

Training in Data and Statistical Analysis:
During the period April to June 2012, worked on data analysis for ecological data collected over the past four years for Habitat requirement for Fish fauna of the Upper Mazaruni river basin Guyana. Training involved preparation of data for CANOCO (Canonical Correspondence Analysis), ANOSIM (Analysis of Similarity) and DFA (Discriminant Function Analysis); to test the effects of environmental variables on fish community structure as a result of mining activities in the Mazaruni Region. **ROM Canada** **April to June 2012**

Coordinator/facilitator: preparation and launching of Ministry of Culture Mash Exhibition at the Guyana National Museum as part of our public programmes for educational development. It was the sixth successful exhibition held as part of our annual programme of activities. **February 2012**

Chief Researcher
Research and Ecological survey of fishes in the upper Mazaruni basin and its tributaries

The research focused on the sampling of all fishes in various reaches of the Upper Mazaruni river basin with ecological data between and including Kukui, kako, waruma, piakwa and kamarang rivers and Assessing species richness and abundance of the fish fauna of the upper Mazaruni river basin, Museum specimen collections etc. This was collaborated with the CSBD University of Guyana, the Guyana National Museum, and Royal Ontario Museum, Canada

November 2011

Country Supervisor:
Supervisor for Commonwealth Association of Museum Internship Exchange Programme between Guyana and Canada; Intern Ms. Renee Homiak from Canada for six months internship in Guyana at several Government Museums. The focus was on developing public programming and conservation for Museums. Oct 2010 to April 2011

MSc research and Ecological survey of fishes in the upper Mazaruni basin and its tributaries
The research focused on the sampling of all fishes in various reaches of the Upper Mazaruni river basin with ecological data between and including Kukui, kako, waruma, piakwa and kamarang rivers and Assessing species richness and abundance of the fish fauna of the upper Mazaruni river basin; Museum specimen collection. This was collaborated with the CSBD University of Guyana, the Guyana National Museum, and Royal Ontario Museum, Canada

March 2011

Coordinator/facilitator: preparation and launching of Ministry of Culture Mash Exhibition at the Guyana National Museum as part of our public programmes for educational development. Feb, 2011

Coordinator/facilitator: preparation and launching of Curio shop at the Guyana National Museum: The shop served to provide additional services for visitors to the Museum as part of a visiting experience. **December 2010**

Coordinator and Organizer: Mexican Exhibition for the Mexican Embassy and the Ministry of Culture, Youth and Sport and National Museum. November, 2010

Coordinator and Organizer: Annual Chinese Exhibition for the Embassy of the People Republic of China and the Ministry of Culture, Youth and Sport.
September 2008 to 2010

Coordinator: Children's Taxidermy Camp 2010: at the Guyana National Museum. It involved lessons and practical work on wildlife biodiversity, environmental problems and taxidermy preparation of simple specimens along with teaching students about roles of Museums. Organizations involved are Iwokrama, University of Guyana, Centre for the Study of

Biodiversity, National Trust and the Environmental Protection Agency.

July-August, 2010

Coordinator Museum Policy Committee:
The objective is to develop and implement a National Museums of Guyana Policy and a Museum Act for all Museums in Guyana. June, 2010- present

Project Manager /Coordinator: Cartographic Museum/map room project, Guyana National Museum, Ministry of Culture, Youth and Sport. The aim was to establish a Map/Cartographic Museum to display Guyana's cartographic heritage, boundary disputes etc from the 1500s to current. Sept 2009 to May, 2010

Coordinator and Organizer: Russian Exhibition for the Embassy of Russia and the Ministry of Culture, Youth and Sport Titled: ''*the Great Patriotic War*" at the Guyana National Museum May 2010

Coordinator/facilitator: Annual Immigration exhibition at the Guyana National Museum. The objectives of the exhibition are: to highlight the Cultural Impacts of Indentured Immigrants since their arrival to Guyana, to develop a program of activities that would promote Cultural Diversity in Guyana using the Indentureship Experience and to commemorate the arrivals of the Chinese, Portuguese, East Indian and African Immigrants to Guyana. **May 2010**

Commonwealth Association of Museum executive Board Member and Youth Representative: Assistance in technical advice and planning programmes, conferences etc, Guyana representative **Feb, 2010-present**

Coordinator for the Preparation of the Megatherium: at the Guyana National Museum. All technical planning, monitoring and evaluation and Implementation of Mega-T specimen within the National Museum **Jan-April, 2010**

Technical Assistant/Assistant Lecturer and Co-Researcher to University of Guyana third and final year Biology students. Pibiri forestry concession, Mabura trail, **Ornithology** and **Herpetology** studies; involved teaching trapping using various methods, collecting, identifying/Taxonomy of species and environmental impact such as food resources, human impact etc. and preservation of specimen for Museum collection. **January 2010**

Field Expedition for excavation of Giant Ground Sloth bones: collaboration with: Berkley University, U.S.A, Walter Roth Museum and CSBD University of Guyana.

Oct. 2009

Chief Instructor and coordinator for The Children's Taxidermy Camp 2009: at the Guyana National Museum. It involved lessons and practical work on wildlife biodiversity, environmental problems and taxidermy preparation of simple specimens along with roles of Museums. Organizations involved are Iwokrama, University of Guyana, Centre for the Study of Biodiversity, and the Environmental Protection Agency. **July 07- August 07, 2009**

Coordinator- Annual Indentureship exhibition, mounted at the Guyana National Museum, highlighting Guyana's Cultural heritage. This exhibition focused on the arrival of Indentured Immigrants to Guyana after the abolition of Slavery. Objectives were to highlight the Cultural Impacts of Indentured Immigrants since their arrival to Guyana, to develop a program of activities that would promote Cultural Diversity in Guyana using the Indentureship Experience, to increase the public`s awareness on the in-depth history of Indentured servants, to assess the impacts of European influences on Guyana. **May 2009**

Commonwealth Association of Museums (CAM) student; the Program is a distance learning program with CAM, involves Museum management, conservation, preservation and restoration and managing visitors to the museum. **April 2009**

Project Manager and coordinator Giant Sloth/Megatherium Project and Recon Field Expedition: responsible for laying out and setting up giant sloth exhibit at the Guyana National Museum and to develop further research in the paleontology and paleobiology areas.

March 2009

Administrator, Taxidermist and Curator (Guyana National Museum): involves managing the National Museum on a day to day basis, financial transactions and budget preparation for National budget for the Museum, planning and executing programme of activities etc

October, 2008-present

Technical Assistant to University of Guyana third and final year Biology students. Chikabaru forestry concession, Ituni trail, region 10, **Ornithology** and **Herpetology** studies; involved trapping using various methods, collecting, identifying species and environmental impact such as food resources, human impact etc. and preservation of specimen for Museum collection.

February 2009

Global Information system (GIS), Global Positioning System (GPS), MapInfo software program training; involves reading of Maps, using of spatial data in map Software, creating maps, and taking coordinates for input.
Guyana Geology and Mines (GGMC) **Jan 2009.**

Taxidermist/Conservator; Completion of a one year training on museum conservation, preservation, restoration and taxidermy and taxonomy; Tr ainer and facilitator: Cuban Museum Specialist and Taxidermist- Mr. Marco Anthonio Olcha; from the Institute of Ecology and Systematics, Cuba. **Dec 2007- Dec 2008.**

External Supervisor/Assessor/Examiner- Faculty of Natural sciences, University of Guyana, Final year Biology Students Research presentations at **Conservation International conference room.** This involved analysis research data presented by research students and grading them according to preparation, content, knowledge and skills, response to questions asked etc. The following researches were examined: A survey of the Avifauna diversity at OMAI Gold Mines Ltd, A survey of the Herpetofauna diversity at OMAI Gold Mines Ltd, To investigate the fecundity rates in *Poceila sp* during capitivity, A study of Oma ponds as a

traditional Natural Resource Management Approach in the North Rupununi, Guyana, Survey of mammals in gallery forest of the Upper Rupununi River, Guyana, Optimizing in-vitro growth for cellulytic bacteria from the cattle rumen, Pilot investigation of the possible anticarcinogenic effects of local fruits on Leukemia, Study of the aquatic Macro-invertebrate community at the Yararibo lake system, Mc Kenzie, Linden, Guyana, A investigative study on primates in the Iwokranma forest conservation. **July 30-September 11, 2008.**

Co-researcher/Assistant supervisor- field survey on 'hassar' Loricariidae catfishes in the Mahaicony conservancy area using drag seining techniques and collecting museum specimens to enhance the national collection. This study is to assess the economic importance of the hassar in Guyana. **August 22, 2008.**

Co-researcher/assistant supervisor- ecological and species diversity survey of fishes at Lake Mainstay Essequibo, Guyana. This research involved the surveying of fishes in the lake using methods of drag seining, gill netting and hand netting. Water parameter tests were conducted on PH, temperature, depth and range finder, along with GPS coordinates. Diurnal and nocturnal surveys were done over a three days period. **Aug 15-17, 2008.**

External Assessor/Examiner- Faculty of Natural sciences, University of Guyana, Final year Biology Research presentations at Conservation International conference room. This involved analysis research data presented by research students and grading them according to preparation, content, knowledge and skills, response to questions asked etc. **July 30, 2008.**

Assistant supervisor/Co-Reasercher: biodiversity survey on avifauna and herpetofauna studies for reclamation project OGML, Omai Gold Mines Limited and environmental effects. Assisting University of Guyana Final year biology students in field techniques and writing criterias for their final year research projects, in addition preparation of ornithological museum study skins and museum wet collections of herpetofauna. **June18-25, 2008**

Cheif/ Head Researcher: Faunal diversity survey and Impact Assessment**,** The Amaila Falls Transmission line Hydropower Alignment project. Assessing and analysing faunal data and reporting on such in relation to environmental impact and checklist on fauna etc.
Potaro region, Guyana, South America **May 2008**

Co-Researcher/Assistant Researcher: Ichthyofaunal survey of the Upper Mazaruni River, **Guyana, South America.** The research focused on the sampling of all fishes in various reaches of the Upper Mazaruni river basin between and including Kukui, kako, waruma, piakwa and kamarang rivers and Assessing species richness and abundance of the fish fauna of the upper Mazaruni river basin; Museum specimen collection. This was collaborated with the CSBD University of Guyana, the Guyana National Museum and Royal Ontario Museum, Canada
14- 25 April, 2008.

Teaching assistant (TA): for **Mammology** and **Ichthyology** studies at **Pibrie- Mabura area** to University biology students. This involved trapping using various methods, collecting, identifying species and environmental impact such as food resources, human impact etc. and preservation of museum specimens (fishes and small mammals). **4-7, April 2008.**

Assistant supervisor/Co-Reasercher: biodiversity survey on avifauna and herpetofauna studies for reclamation project OGML, Omai Gold Mines Limited and environmental effects. Assisting and teaching University of Guyana Final year biology students field techniques and writing criterias for their final year research projects**.** **Feb 27- March 5, 2008.**

Anthropological (Scientific) Officer and Taxidermist at the **Guyana National Museum**, chief functions and protocols involves head of taxidermy department with a supervisory roles and responsibility for anthropological assistants and duties thereof to the department. Responsibility for planning and coordinating field works for specimen collections, analysing the data for biological and other natural history specimens in the museum laboratory and providing updated information on Natural history (biodiversity) aspects, preparation of scientific study skins and mounting of taxidermy specimens. Cleaning, conservation, preservation and restoration of natural history collections a.g. Deputy to Administrator with duties of management at the National Museum among many other assigned duties which includes lectures and tour guides to various organisations, schools and the general public. **June 2007 – October 2008**

Assistant and external supervisor;
Supervisory role to students at the University of Guyana with respect their final year research projects. Involves identification and classification of biological specimens along with relevant information and approaches in analysis of data. **2005 –present**

Teaching Assistant (TA)
Mammology and **Ornithology** studies TA at **CEIBA** for University biology students. This involved trapping using various methods, collecting, identifying species and environmental impact such as food resources, human impact etc. and preservation of specimen for Museum collection. **Nov 16- 19 2007**

Assistant supervisor/ researcher on final year research project to University of Guyana student: studies based on the use of entomology or insects in forensic studies. Done by; C. Horatio. **July - Oct. 2007.**

Chief Instructor and deputy coordinator for The Children's Taxidermy Camp 2007 at the Guyana National Museum. It involved lessons and practical work on wildlife biodiversity, environmental problems and taxidermy preparation of simple specimens along with roles of Museums. Organizations involved are Iwokrama, University of Guyana, Centre for the Study of Biodiversity, and the Environmental Protection Agency.

July 07- August 07, 2007.

Teaching assistant (TAs) for **Mammology** and **Ichthyology** studies at **CEIBA** to University biology students. This involved trapping using various methods, collecting, identifying species and environmental impact such as food resources, human impact etc. and preservation of specimen for Museum collection. **April 2007.**

Research field assistant on **Ornithology** studies and **bird museum** (wet and dry) collections at Paurima and Holitipu, Upper Mazaruni region #7. This included preparation of specimens, trapping of birds, identification of birds. **Feb-March 2007**

Teaching assistant (TAs) for **Ornithology** and **Herpetology** studies at **CEIBA** to University biology students. This involved trapping using various methods, collecting, identifying species and environmental impact such as food resources, human impact etc. and preservation of specimen. **Nov 2006**

Head faunal researcher/Assistant researcher for **Environmental Impact Assessment** (EIA) on floral and faunal studies at Guyana gold fields, Aurora, Upper Cuyuni River**.** **Oct. 2006.**

Research field assistant on **floristic studies** and sample collections at Kaieteur National Park, Amatuk, Madahia, Eagle Mountain and Micobe. This was done in Collaboration with Smithsonian Institute and Centre for the Study of Biodiversity. **August- sept. 2006.**

Head faunal researcher/Assistant researc her for **Environmental Impact Assessment** (EIA) on floral and faunal studies at Guyana gold fields, Aurora, Upper Cuyuni River**.** **July 2006.**

Assistant researcher for **Environmental Impact Assessment** (EIA) on baseline study of aquatic environment at Yararibo old mines Omai bauxite mining inc. (OBMI) Mc Kenzie, Linden. **June 2006.**

Teaching assistant (TAs) for **Ichthyology** studies at CEIBA to University biology students. This involved trapping using various methods, collecting, identifying species and environmental impact such as food resources, human impact etc. and preservation of specimen. **April 2006.**

Centre for the Studies of Biological Diversity Volunteer/ researcher; involves local field research, expeditions, techniques in trapping, DNA and Tissue sampling, Study of Biodiversity and ecological studies, Museum techniques and preparation of Museum Specimens, training of Biology students, research with Smithsonian Institute and Royal Ontario Museum, Auburn University, and Texas A&M university. **Jan. 2006-present.**

Research field assistant on **ichthyology** studies/survey and sample collections at Iwokrama, Annai, Piarra, Takutu river, Ireng river, Kurupukari and upper Essequbo River. This involved trapping using various methods, collecting, identifying species and preservation of specimen. **Nov-Dec. 2005.**

Teaching assistant (TAs) for **Mammology** and **Ichthyology** studies at CEIBA to University biology students. This involved trapping using various methods, collecting, identifying species

and environmental impact such as food resources, human impact etc. and preservation of specimen. **Nov 2005.**

Ministry of health: Government Analyst Food and Drugs Department. Work study attachment, functioning as **Laboratory technician** in the department of food chemistry, water chemistry, microbiology. **Jul-Sept. 2005.**

Teaching assistant (TAs) for **Ornithology** and **Herpetology** studies at CEIBA to University biology students. This involved trapping using various methods, collecting, identifying species and environmental impact such as food resources, human impact etc. and preservation of specimen for Museum collection. **Apr. 2005.**

Faunal researcher/Assistant researcher for **Environmental Impact Assessment** (EIA) on floral and faunal studies at Guyana gold fields, Aurora, Upper Cuyuni River**.**

Jan. 2005.

Teaching assistant (TAs) for **Ornithology** and **Herpetology** studies at CEIBA to University biology students. This involved trapping using various methods, collecting, identifying species and environmental impact such as food resources, human impact etc. and preservation of specimen for Museum collection. **Nov 2004.**

Ornothological field and taxidermy training: this involved the field techniques in trapping, taxonomic identification of birds, taxidermy-skinning, preservation of skins and stuffing, Preparation of bird reference collections for museums. **Aug. 2004.**

Guyana Zoo education volunteer: include giving informal cage side talks, guided zoo tours, and policing the zoo and giving factual information on animals in the zoo

Jun 2004-present.

Contributing Researcher to the development of the Bird checklist of Guyana, Herpetofauna and Mammalian fauna Checklist of Guyana. Jan 2004 to Present

Ministry of health: Work study attachment at the **Georgetown Public Hospital** in **Orthopaedic clinic**, duties include setting and casting of broken bones and removal of casts.

Jul-Aug. 2001.

Current/Pass Project Supervision: BSc students

Adele Elcock, The effects of various nutrient types on the rate of eutrophication ex situ.

Ajuba Clarke, Survey, seasonal diversity and diet of Estuarine and Marine fishes from the Demerara and its immediate coast.

Mohini Sooklall, Survey of Sting Ray diversity on the Coast of Guyana using various gear types.

Mohinder Deven Itwaru; To investigate the effects of applying different sources of animal manure on the yield and growth rate of tomatoes (Solanum lycopersicum) plants grown Geoponically.

Bhagmadai Sooku; Bio-survey on water quality and fishes in central Georgetown, with assessment of morphology, diet and heavy metal content in tissues of selected species.

Ferial Pestano; An investigation on entamo-pathogenic fungus found on insects at the University of Guyana campus. (Main Supervisor: Prof. A. Ansari)

Jenelley Lewis; The effects of brewery wastewater on tilapia sp at Banks DIH ltd.

Nichloas Ali; Investigating the efficiency and effectiveness of the wastewater treatment at the Banks DIH wastewater treatment plant.

Mark Bastian; Variations of microbiota found in the alimentary canals and on the external bodies of Rhinella marina toads within rural and surban areas. (Main Supervisor: Prof. A. Ansari)

Devya Hemraj; The effects of Neme and pronto on tadpoles and paddy bugs in rice fields of Guyana. (Main Supervisor: Ms. Jewel Liddel)

Kellisha Edwards, Topic: Quantitative Analysis of Heavy Metals in Sugar Cane (*Saccharum officinarium*) in Administrative regions (three, four and six) of Guyana. **Lab analysis**: testing sugar cane samples (stem, roots and leaves) for the presence of **heavy metals** which includes **Cadmium (Cd), Copper (Cu), Lead (Pb), Nickel (Ni), Iron (Fe)** and **Cobalt (Co).**

Lokaya Wrights, Topic: Phytoremediation and Adsorption of contaminated water using Duckweed (*Lemna minor*) and Coconut (*Cocos nucifera*) shell Biochar. **Lab analysis**: test for **Iron, Lead** and **Manganese** in Coconut Biochar and Duckweed samples.

Sueellen Ewing-Chow, Topic: Gastrointestinal and external Parasites found among Monkeys in captivity at the Guyana National Zoological Park

Radha Permaul, Topic: Oil content in selected species of algae in Guyana. **Lab analysis**: measuring the rate of growth and biomass (density) of algal species samples and testing for the amount of oil generated from the various algae species grown under different conditions.

Curtly Critchlow, Topic: The prevalence of Helminths found in cattle and pigs that are slaughtered at the Georgetown Abattoir**.**

Vishaul Bhryo, Topic: An ecological study of the Rufous Crab Hawk (Buteogallus aequinoctialis) and the effects of anthropogenic activities on their habitats along the Coast in Regions 3 and 4, Guyana.

Pryia Singh, Topic: To investigate microbiological organisms that is common among selected fruits and vegetables in local markets.

Tameka King; A survey of the Avifaunal diversity at OMAI Gold Mines Ltd (Main Supervisor: Mr. C. Bernard) 2008

Rydel Moore; A survey of the Herpetofauna diversity at OMAI Gold Mines Ltd (Main Supervisor: Mr. C. Bernard) 2008

Odile Broomes; Mammalian Diversity in mined and non-mined sites at at Yararibo old mines Omai bauxite mining inc. (OBMI) Mc Kenzie, Linden. (Main Supervisor: Mr. C. Bernard) 2008

Romeo Singh; Survey on 'hassar' Loricariidae catfishes in the Mahaicony conservancy area (Main Supervisor: Mr. C. Bernard) 2008

Roschelle Grant; Ecological and species diversity survey of fishes at Lake Mainstay Essequibo, Guyana (Main Supervisor: Mr. C. Bernard) 2008

Candace Horatio; The use of entomology or insects in forensic studies (Main Supervisor: Mr. C. Bernard) 2007

Conferences/Seminars/Training Courses/Workshops

Public proposal Presentation

Impacts of environmental degradation on fish assemblage structure in the Upper Mazaruni River Basin, with description of their community structure and habitat requirement, Guyana, South America by Elford Liverpool **March 2013**

Attended Training programs in Supervisory Management at Public Service Ministry
June, 2010

Glimpses of Amazonia: A display and celebration of Amerindian heritage Month 2009. Walter Roth Museum of Anthropology.
Sept 15, 2009

Introduction to the taxonomy of amphibians of Kaieteur National Park, Guyana, By Philippe Kok and Michelle Kalamandeen,
Sept 2009

Three part lecture series, Walter Roth Museum of Anthropology**, Umana Yana**
August, 2009

The Launching of Kaieteur National Park Management Planning Process, Dr. Graham Watkins
A celebration of Kaieteur by: Mr. Bobby Fernandes. **June 25, 2009**

Conference: Theme; Communities and Ecological Sustainable Development;

- **The Guiana Shield Initiative project- Lesson of Iwokrama;** Dr. Raquel Thomas
- **Galapagos-Both sides of the coin;** Dr. Graham Watkins

April 22, 2009.

GIS, GPS and MapInfo training; Guyana Geology and Mines Commission
Jan 2009.

Taxidermy, Museum conservation, preservation and restoration training at the Guyana National Museum
Training executed by Mr. Marco Olcha, Cuban Museum specialist.
Dec 2007-Dec 2008.

A survey of the Avifaunal diversity at OMAI Gold Mines Ltd: by Ms. Tameka King**.**
September 11, 2008.

A survey of the Herpetofauna diversity at OMAI Gold Mines Ltd: By Mr. Rydel Moore.
September 11, 2008.

To investigate the fecundity rates in Poceila sp during capitivity. By; Ruth Rampersaud.
September 11, 2008.

A study of Oma ponds as a traditional Natural Resource Management Approach in the North Rupununi, Guyana. By; Diana Seecharan.

July 30, 2008.

Survey of mammals in gallery forest of the Upper Rupununi River, Guyana. By Ms. Diana Singh. **July 30, 2008.**

Optimizing in-vitro growth for cellulytic bacteria from the cattle rumen. By; Padmini Ragnaugth. **July 30, 2008.**

Pilot investigation of the possible anticarcinogenic effects of local fruits on Leukemia. By; Seleyna Headley. **July 30, 2008.**

Study of the aquatic Macro-invertebrate community at the Yararibo lake system, Mc Kenzie, Linden, Guyana. By; Crissaundra Mohabir.

July 30, 2008.

An investigative study on primates in the Iwokranma forest conservation: CI conference room. June 2008.

Museum development workshop at the Guyana National Museum, Lecture room. Aspects on history, management and maintenance of the museum were scoped, along with staff development, approach to the visiting public, museum conservation and policies, it also entaled museum education and preservation principles.
PREPARED AND PRESENTED BY: MS. T. BOATSWAIN

Dec. 11- 14, 2007.

INTERNATIONAL CONFERENCE ON THE STATUS OF BIOLOGICAL SCIENCES IN THE CARIBBEAN AND LATIN AMERICAN SOCIETIES: HOSTED BY THE DEPARTMENT OF BIOLOGY, FACULTY OF NATURAL SCIENCES, UNIVERSITY OF GUYANA AT BUDDY'S INTERNATIONAL HOTEL, PROVIDENCE.

September 24- 25, 2007

ASSISTANT AT THE CHILDREN'S ZOO CAMP: FACILITATED BY THE GUYANA NATIONAL ZOO AND WORLD'S WILDLIFE FUNDS (WWF): HOSTED BY **DR. FELIX (WWF**), TOPICS INCLUDED MARINE TURTLES, THEIR STATUS, AND CONSERVATION POLICES AND STRATEGIES. **September 22- 23, 2007**

Presentation on the floristic studies in selected regions of Guyana. By Dr. K. Redden Jan, 2007.
.

Guyana Zoo education volunteer training: Jun-Aug 2004.

Centre for the studies of Biological Diversity Volunteer training.

Jan. 2006-Present.

Training on basic laboratory techniques: Government Analyst Food and Drugs Department. **Jul-Sept. 2005.**

Ornothological field and taxidermy training: CSBD and Smithsonian Institute Aug. 2004.

Laboratory work on sample/specimen collections from field expeditions/works and other researches done in Guyana 2004- Present.

Skills

Basic Electronics, Carpentry, Masonry, Computer (Excel, Word, PowerPoint, Publisher and more), Moulding and casting, tanning etc.

Hobbies

Football, cricket, swimming, running, meeting and interacting with people, music, studying, life guarding etc.

Reference

PHILIP DA SILVA - Senior Lecturer, University of Guyana, Tain Campus, Berbice.

DR.HERNANLOPEZ FERNANDEZ- Assistant Professor, Department of Ecology and Evolutionary Biology, University of Toronto, Canada and Curator, Royal Ontario Museum, Toronto Canada.

DR. NATHAN LUJAN- NSF International Fellow, Royal Ontario Museum, Toronto Canada

DR. JAMES G. ROSE - Director of Culture, Department of Culture, Ministry of Culture, Youth and Sport

PROF. ABDULAH ANSARI- Professor, Department of Biology, Faculty of Natural Sciences, University of Guyana.

Leon Moore

Leon Moore Nature Experience: Consultant Coordinator/Zoologist

Mr. Moore specializes in the field of ornithology and is actively concerned about Guyana's ecosystem and the preservation of its wildlife. He enjoys working with people, is experienced in the photography of birds and mammals, and is a knowledgeable nature guide.

Experience: 10 years' experience in bird observations and the evaluation of ecosystems in Guyana and other countries such as Suriname and Brazil.

Email: leon.moore@erm.com

Education

- High School Diploma, Linden Foundation Secondary School, Guyana, 2002.

Languages

- English

Fields of Competence

- Hospitality THAG Certificate
- Tour Guide Training
- Water Quality Testing Training
- Emergency First Responders Training
- Conservation and development
- Preservation of wildlife
- Ornithology
- Photography

Key Industry Sectors

- Tourism

Honors and Awards

- Tour Guide of the Year (Guyana Tourism Authority)

Publications

- Developed the Rock View Lodge Bird List

Key Projects

Coastal Mapping Sensitivity and Bird Survey
Nov 17 to 24, 2019. Conducted for Environmental Resources Management (ERM)

Coastal Mapping Sensitivity and Bird Survey
Apr 16 to 24, 2018. For Environmental Resources Management (ERM)

Key Projects Prior to Joining ERM

Guyana Defense Force
2002–2006

Auto Mechanics
2007–2008

Guest Service Officer, General Tour Guide
June 2008–June 2009 - Developed Bird List.

Bird Censor as Field Officer
August 2008. Baganara Island Resort - GATBS /Wetland International in the Essequibo River.

Bird Guide Tours and Surveys
Jan 2008–2017. Bird Guide Tours and surveys in Regions 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10 Guyana.

Rock View Lodge
Sep 2009–2012. Tour Guiding, Appointed Team Leader, Assistant Tourism Manager, and General Assistant Manager.

Tour Guide
Jan 2012–Feb 28, 2014. Atta Rainforest Lodge & Iwokrama Canopy Walkway

BBC Guyana Documentary
Oct 2013. Worked with BBC team conducting a documentary in Guyana.

www.ebirds.org (Guyana) volunteer
Apr 6, 2014. Started volunteering as regional reviewer.

Assistant Instructor Bird and Tour Guide
Oct 2014. Training at Iwokrama International Research Center for rainforest conservation and development.

Conducted Bird Guide Training
Nov 2014. At Iwokrama International Research Center for rainforest conservation and development.

Bird Survey
Aug 20 to Sep 21, 2016, at Guyana Goldfields Inc.

Bird Survey
Feb 6 to Feb 24, 2017. At Guyana Goldfields Inc.

Bird Survey
June 4 to June 13, 2017. At Environmental Services & Support (ESS) in Suriname.

Bird Survey
Feb 26 to Mar 6, 2018. At Guyana Goldfields Inc.

Shorebirds Survey
Along the coast of Guyana for (United States Shorebirds Consecration Plan). Currently in progress.

Noam Raffel

GIS/Geospatial Data

Noam has 8 years of experience in the field of GIS. With a technical geospatial background, Noam focusses in the energy sector, including gas facilities, power generation and remission, and renewable energies. He has prepared environmental, social, and cultural impact assessment plans for numerous exploration and development projects in North America, South America, Africa, and the Middle East. Noam has worked with ExxonMobil for multiple projects while at ERM, including a project using 3D Lidar modeling of sites in Texas; developing an online dashboard for geospatial environmental data for ExxonMobil Qatar; and various projects for EEPGL in Guyana. He has been a part of ERM's support to EEPGL in Guyana since 2017, focusing on mangrove health monitoring, coastal sensitivity modeling, overseeing the ecosystem services, coastal bird, offshore bird, and mangroves.

Experience: 8 years of experience in GIS and remote sensing

Email: noam.raffel@erm.com

Education

- Master of Arts in Geographic Information Systems, Clark University, Worcester, MA, 2014
- Bachelor of the Arts in Geography, Clark University, Worcester, MA, 2013

Languages

- English, native speaker
- Hebrew, fluent

Fields of Competence

- GIS Modeling/Remote Sensing/WebGIS
- Social, Health and Environmental Impact Assessment
- Field Survey and Reconnaissance Techniques
- ArcGIS Desktop, ArcGIS Collector, ArcGIS Online, Survey123, IDRISI TerrSet, ESA SNAP, QGIS, IDRISI, GRASS, ENVI, SPSS, Adobe, Path Finder, Excel, Python, MS Access

Key Industry Sectors

- US Government
- Oil & Gas
- Mining
- Linear Infrastructure
- Climate Change
- Health & Communicable Disease Modeling

Key Projects

Social and Environmental Geothermal Site Selection, Mexico
Noam led the GIS team in creating a site selection tool for geothermal projects across 29 sites in Mexico. This project included collecting, developing and managing geospatial data for block areas across the country, as well as landcover modeling for all areas. He created biodiversity, environmental, social and cultural heritage sensitivity models for all sites. Noam developed a user-friendly online tool using these sensitivity models to rank and identify areas for geothermal site selection.

Transportation Project Oversight, Benin and Ivory Coast
Noam develops an online tool to manage large-scale transportations projects in two countries.
This work includes managing massive imagery databases and uploading them to the cloud. Additionally, Noam oversees survey management and creation, and project progress and management.

Offshore Development – Guyana
Noam assists the geospatial team for a large offshore development project. He leads the geospatial approaches to biodiversity and ecosystem services data collection and modeling, along with environmental and technical siting of potential on-shore infrastructure. He participates in the shoreline and mangrove field surveys. Noam uses a variety of software platforms for this work, including mobile digital data collection and secure web-hosted GIS.

Climate Change Shoreline Analysis, Tobago
Noam led the GIS team in a climate change analysis project for an international financial institution, using satellite imagery over multiple dates to measure coastline changes. He developed landcover models to analyze how and why the landscape changed over time. Additionally, he mapped local coral reefs and created a “bathtub” model to measure how rising sea levels are expected to change the local shoreline.

Modeling for Major Energy Company
Noam modeled all forest and agricultural plots in a five-mile buffer of the 600-mile pipeline using Sentinel 2 10 meter resolution imagery. He also assisted with the culture heritage team to create viewshed and 3D models of potential disturbances created by the project.

Impact Assessment, Mozambique
ERM conducted an ESIA report for the potential impacts of a GTL plant on the Afungi Peninsula in Mozambique. Noam led the geospatial team to assist with the biodiversity, social, and marine teams. This included creating a landcover module from Worldview 2 and 3 imagery, creating social and biodiversity sensitivity and constraint models as well as identifying near shore coral reefs.

Climate Change and Urban Development Plan, Emerging and Sustainable Cities Imitative
Noam was tasked with classifying and analyzing landcover change over a 30-year period using Landsat Satellite Imagery. He used the Landsat results to predict urban growth over the next 50 years. For this project, he also used high-resolution Worldview 2 satellite imagery and field verification to develop a land use map of the entire city. Noam also, developed a tool to model the factors that determine future development demand.

E&S Screening (Transmission-Line) and GAP Analysis (Hydro)
Noam classified the landcover of three different transmission routes using Sentinel 2 satellite imagery. He used the classification results as well as other variables to determine the most optimal route for the transmission line.

Impact Assessment, Nicaragua
Assisted in assessing the impact of a potential canal through Nicaragua. Noam was responsible for managing the archeology and built heritage database that may be potentially affected by the canal. He assisted in the development of a sensitivity model to

assess high risk location of archeology. Noam modeled and mapped the cumulative impact assessment of the project.

Cultural Heritage, Guinea
Assisted in finding potential cultural heritage sites in the location of a potential mine in Guinea. Noam created a sensitivity model from LIDAR imagery to assess where potential sites are located. The model was tested against known sites and proved to be highly accurate.

Cultural Heritage for Manufacturing Plant
Noam was responsible for reviewing LIDAR data and satellite imagery to inspect for potential cultural heritage finds. He collects data in the field to assist with both archeology and built heritage for a plan on building a manufacturing plant in rural West Virginia.

Development of Decision Support Protocols and Procedures to Strengthen Health Sector Response to Severe Weather Risks and Climate Change, Mozambique
Noam was a GIS specialist on this project, which included countrywide modelling of risks to human health from climate change and severe weather events. Activities performed include:

- Generating country-wide landcover & land use model (including remote detection of agricultural areas from imagery analysis)
- Collecting GIS data on human health issues
- Generating precipitation and temperature prediction models
- Running a geographically weighted regression analysis to link certain types of weather events and climate change to downturns in human health
- Using current patterns project which areas in Mozambique are at highest risk for human health issues in the future.

Windfarm Cumulative Impact Assessment, Pakistan
Provided a cumulative impact assessment of over 20 windfarms in Sindh Pakistan. Noam was in charge of providing all the figures and modeling. This includes a visual impact assessment, a land cover model, and auditory modeling.

ERM Foundation and Foundation for Africa, West Africa
Noam built a method to test forest fragmentation and its relation to past and present Ebola outbreaks using advanced statistics and remote sensing.

Screening Assessment, Ethiopia & Djibouti
Noam was a GIS specialist for an aligned screening assessment of a proposed pipeline running from the port of Djibouti to Awash in Ethiopia. He was responsible for generating landcover/land use models that included the classification of agricultural land and generating resource constraint models that were used to site the pipeline using a least cost routing analysis in order to avoid major impacts to the society and the environment.

Haimwant Persaud
GIS Specialist

195 Schoonord
West Bank Demerara

Pinar Del Rio, Cuba
2009

CERTIFICATION

Certified GIS Professional (GISP)
GIS Certification Institute
Des Plaines, Illinois, USA
2015

EXPERIENCE

Year	Employing organization	Country	Summary of activities performed relevant to the Assignment
2020	Deen + Partners/ Ministry of Education Guyana	Guyana	**GIS Specialist** • Spatial Data collection for the development of a Natural Hazard Risk Profile for the Education Sector. • Create a Geospatial Database for the Natural Hazard Risk Profile for the Education Sector. • Conduct Spatial Analysis for Risk and Vulnerability Assessment. • Conduct Training on Spatial Data capture for Natural Hazard Risk Profile for the Education Sector.
2020	Landell Mills International Ltd	Guyana	**GIS Specialist** • Develop pertinent data contained in shapefiles for hydrology, vegetative cover that includes Mangal ecosystem vegetation. • Develop the boundaries of the SPA that protects the Mangal vegetation along the tributaries and rivers. • Legally defined Amerindian territories, existing concessions, settlements, and the Shell Beach Protected Area • Calculate the total area of the SPA and the mangals within it, as well as rivers and their commonly used names.
2019	Cheri Sugal Consulting/FCPF	Guyana / USA	**GIS/Land Tenure Specialist** • Analyze the Land Tenure situation in Guyana • Analyze the total non-forest by Land Tenure Class • Analyze the rate of deforestation by Land Tenure Class for the past three decades. • Analyze the total standing forest by Land Tenure Class as of January 1, 2019.

			• Develop scenarios for the allocation of Carbon Benefits from REDD+ activities by Land Tenure Class in Guyana. • Make projections on Emission Reduction for Guyana to achieve its NDC.
2018-2019	Vivid Economics/ Inter-American Development Bank (Climate Resilience Support for the Adequate Housing and Urban Accessibility Program in Georgetown)	Guyana	**GIS and Remote Sensing Consultant** • Identify and aid in the sourcing of spatial data required. • Development of historical urban footprint of Georgetown. • Development of a land-use inventory within Georgetown. • Application of urban growth model of Georgetown.
2018	Caribbean ecosystems limited	Jamaica/ Guyana	**GIS and Remote Sensing Consultant** • Develop a flood risk model for Guyana Coastal plain.
2018	Caribbean Aqua-Terrestrial Solutions/GIZ GmbH	Guyana/ CARICOM	**GIS and Remote Sensing Consultant** • Establish an inventory of archived SAR satellite data available for Iwokrama with a focus on coverage for the historical period (pre-2000). • Map and Assess of Change in Forest Area for 2000, 2014, and 2017. • Develop a capacity-building framework, for the processing, interpretation of data, and quality insurance of remote sensed SAR data.
2018	United Nations Environment	Guyana	**National Consultant – Urban Environmental Assessment** • Establish a methodology for environmental assessment. a) Detailed municipal solid waste profile of the Centre and an estimate of industrial waste from mining b) Geophysical profile of the city and its boundaries c) The topography of the town d) Fragile ecosystems

			e) Geological structure and soil type f) Water resources and water consumption distribution g) Climate data (rainfall, atmospheric temperature) h) Energy and transport profile i) Socio-economic profile • Develop a report consolidating the baseline data collected in the implementation of the methodology and providing recommendations for further work as well as mechanisms to continue data gathering. • Develop communications materials that present the current situation and future scenario.
2017-2018	Engineering and Management Consultancy Group	Guyana	**GIS Consultant** • Spatial Modeling of Kwakwani to determine the locations most vulnerable to flooding • Identify using spatial models the reason/s for the occurrences of flood • Develop relevant Spatial datasets • Develop Spatial Database • Geocode locations
2017-2018	GeoIdeas/Crime mapper application	Guyana	**GIS Consultant** • Develop spatial Database for crime mapping application crimemapper.gy • Conduct system design and database models • Aid in the Development of a Geo-coder for crime mapping in Guyana.
2014-2020	Ministry of Natural Resources	Guyana	**GIS Manager** • Responsible for the overall management and the day to day activities of the Geographic Information Systems (GIS) Unit, within the Ministry of Natural Resources and the Environment. • Assist in the provision of information to the Ministry for proactive action in monitoring, regulation, and compliance by the Ministry and its agencies.

- Responsible for the general management, integration, documentation, and dissemination of spatial data to the Ministry and its agencies.
- Conduct spatial analysis on data collected, including the interpretation of any available up-to-date Remote Sensed Imagery.
- Conduct accuracy and consistency checks on data received from the different natural resources agencies.
- Contribute to the collection and inventory of available reports, maps, aerial photographs, satellite images, digital data, and scientific articles related to land use and natural resources management.
- Prepare and provide reports and digital maps (at appropriate scales) and accompanying quantitative analyses.
- Design and developing spatial databases for the storage, retrieval, manipulation, and analysis of data.
- Research and explore opportunities for the acquisition of imagery that is readily available to achieve the unit's objectives.
- Assist in the development of Standard Operating Procedures (SOP's) necessary for the functioning of the unit.
- Develop web mapping applications and services that support decision making.
- Ensure that the Geoportal site is up and running acceptably, and perform any additional functionality as is required.
- Develop metadata for key datasets in coordination with the respective data owners.
- Develop maps, reports, and splashboard type charts as required by the Ministry and GIS Committee
- Develop manuals and Standard Operational Procedures as it relates to key operations of the platform.
- Establish and maintain professional cooperation, linkages, and partnership with government and other institutions whose intentions and programs of work are related to the above.

2017-2018	Development, Policy, and Management Consultants.	Guyana	**GIS Specialist** • Building survey instrument into an electronic platform • Facilitating training exercises for enumerators and supervisors on the use of the questionnaire in electronic format • Maintaining an online data collection system during the conduct of the survey
2017	Ministry of Public Infrastructure	Guyana	**GIS Consultant** • Creation of a Spatial Decision Support System for the National Task Force Commission. • Acquiring the Required GIS Data from Sources • Creation of Conceptual Database Models • Creation of Logical Database Models • System Design • Database Creation • Data Scrubbing and Loading • Data Presentation in GIS Environment
2016	Hamburg Port Consulting, The Consultancy Group, and IDB,	Guyana	**GIS Specialist** • Investigate and Map the origin and destination of cargo to and from Manaus and Roraima (Boa Vista in particular) to determine the current international volumes traded with North America, the Caribbean, and Europe. • Collect and map commodity flow data originating from and destined for Amazonia and Roraima including internal Brazilian trade. • Analyze Yearly cargo flow data should be collected for the period from 2000 to the latest available year to reveal the main trends. • Geocoded by commodity type and mapped for the earliest and most recent years for which most complete data are available for the major commodities only.

			• Analyze the origin and destination of time-sensitive and/or refrigerated cargo. • Identify the characteristics of the land and maritime shipping networks involved in the cargo flows of the same major commodities. • Identify, describe, and Map transport modes along with a combination of modes serving the different trade routes. • Analyze maritime transport data including the number of vessels by ports relevant for each trade route in terms of international and internal trade, vessel size (net registered tonnage), vessel types (deep sea, short sea), and countries of the registry. • Identify and map vessel movement patterns in the transshipment ports should be identified. A sample of actual vessel monthly movements should be collected from geo-coded data sources such as Lloyds List Intelligence. • Identify and map the main trade corridors to understand the size and intensity of trade flows and/or several commodities relevant for both internal and international trade corridors to understand their degree of spatial concentration. • Identify and analyze spatially the supply chains for the main export commodities in the identified maritime trade corridors. • Identify and map exporters-importers, shippers, producers, and those engaged in international transit movements in the Roraima, Manaus, Paramaribo, and Cayenne. • Develop a geodatabase (GIS database) to accommodate the spatial data developed for this project and is required for the second deliverable.
2016	Development Policy and	Guyana	**GIS Consultant** • Create maps and graphs as required by the

	Management Consultants		Client, using GIS software and related equipment, • Meet with data providers as necessary, to define data needs, project requirements, and required outputs, • Identify, locate and obtain existing databases that may be useful for the study, • Gather, analyze, and integrate spatial data from the Client and determine how best the information can be displayed using GIS techniques, • Compile geographic data from a variety of sources including censuses, field observation, satellite imagery, aerial photographs, and existing maps to produce a gradation of hotspots in the six (6) mining districts of Guyana, • Analyze geographic relationships among varying types of data as provided by the Client.
2012-2013	Health Assessment Research Center	Coachella Valley, USA	**GIS Intern** • Develop an interactive Web GIS application for the visualizing of health indicators, behaviors, and disparities in the Coachella Valley • Geo-code data about the health indicators, behaviors, and disparities by cities. • Create a Spatial database to house the datasets
2012-2013	Amazon Cooperation Treaty Organization (ACTO), GIS Consultant,	Brazil	**GIS Consultant** • Support the development of planning and technical-operational execution of the project at the national level; • Participate in planning meetings for the installation of the Observation´s Rooms; • Support the development of routine mapping and cartographic quality control in the mapping and spatial analysis of the characteristics and dynamics of the landscape (physical and biotic environment, land use, deforestation, and logging, among

others) using the System TERRA AMAZON INPE;
- Support the analysis and interpretation of satellite images to generate or update databases of geographic information;
- Use geoprocessing tools for mapping and spatial analysis and Spatio-temporal;
- Participate in updating and/or structuring of a database of geographic information;
- Participate in the preparation of reports and/or publications that are based on information generated by the monitoring system of deforestation;
- Actively participate in project training courses;
- Advise national experts working in the area of geo-technologies for monitoring deforestation;
- Make the necessary communications with the INPE Amazon to support the processes of implementation of systems and methodologies for monitoring deforestation;
- Prepare at the technical and logistical level, missions or field trip as part of the monitoring process of the project and participate in them;
- Develop other related duties assigned to him/her by the National Technical Coordinator.

2010-2012 Guyana Mangrove Restoration Project — Guyana

GIS Consultant

- Interpret satellite imagery/aerial photos of Guyana's coast to create baseline mangrove forests.
- Develop relevant datasets to aid in the management and monitoring of mangrove forests.
- Data collection and geocoding for map creation and analysis.
- Design and develop an appropriate GIS database to capture, store, analyze, manage, and generate GIS data and reports.

2009-2014	Guyana Forestry Commission	Guyana	**Assistant Commissioner of Forest/GIS Manager** • Assisting with the preparation of work plans and budgets for the division • Overseeing and supporting the implementation of all GIS/RS work of the FRIU • Supporting efforts aimed at consolidation, archiving and preprocessing of all GIS data necessary for the MRVS • Providing technical support to the development of the main areas of the MRVS forest areas assessment and change monitoring activities including the development of the benchmark forest map, assessment of historic forest are a change • Supporting independent accuracy assessment work on forest area mapping and change detection • Liaising closely with relevant natural resources agencies in Guyana to support MRVS process • Supervising GIS activities, evaluating resource information, and preparing reports. • Providing information and mapping service to the GFC and Forestry sector. • Researching and advising GFC on forest resources information and GIS practices quarterly. • Promoting and understanding of the use of resource information by the forest sector and stakeholders quarterly. • Assisting with the preparation of forest resource information. • Facilitating Interagency collaboration amongst relevant government agencies involved in GIS activities. • Providing recommendations for training in GIS and related skills development. • Participating in REDD activities, including procuring, compiling, processing of satellite images for change detection purposes as outlined in methodology development for the GFC by Poyry.

- Developing standards for conducting GIS/RS work at the GFC.
- Assisting in updating GFC guidelines on Sustainable forest management.
- Providing training to FRM field staff on relevant GFC/FRMD guidelines.

RECENT WORK

- Climate-resilient urban growth for adequate housing and urban accessibility in Georgetown, Guyana.
- Object-based image analysis approach to determine the fallow periods for shifting cultivation in indigenous communities in Guyana.
- Project Manager: Development of the Ministry of Natural Resources, Natural Resources Information System (NRIS). http://nris.gim.gov.gy/.
- An Assessment of the Loss of Mangrove Stands in Mahaica – Berbice, Guyana.
- Feature level fusion of multi-temporal ALOS PALSAR and Landsat data for mapping and monitoring deforestation and forest degradation in Guyana.
- Web-Based GIS Application for Monitoring Community Health.

- Spatial Analysis and Modeling to determine the causes of flooding in Coomacka Region #10
- Assessment of Forest using RADAR technology in the Berbice area.
- Standard Operating Procedures for Guyana's MRVS Interim Measures.
- Dynamic Study of Vegetation within the City of Pinar del Rio.
- Guyana Forest Carbon Stratification and Sampling Design.
- Near-real-time analysis of forest change in Guyana.
- Temporal analysis and quantification of Mining deforestation.
- Prioritization of Hot Spots for Monitoring and enforcement of Gold Mining Activities in Guyana.
- Guyana – Brazil Land Transport Link and Deep Water Port Market Study.
- Development of Guyana Geoportal, web and mobile applications. http://data.gim.gov.gy/.
- Development of desktop-based GIS applications for Natural Resources Management.
- Development of mobile data collection application for Natural Resources Management. http://collect.gim.gov.gy/.
- SPATIAL DATA: A common infrastructure can lead to development in Guyana.
- Rainfall Distribution Using Kriging Interpolation in Rice Producing areas of Guyana.
- Mapping and Inventory of the Coastal Zone Forest in Guyana.
- Vegetation Map of urban and suburban of a sector of the city of Pinar del Río. Cuba.
- Applied Geographical Information Technology in the designing of forest roads Sector; Outlet of the River Cuyaguateje. Cuba.
- Study of vegetation around water bodies in urban and suburban zones within the city of Pinar del Río. Cuba
- Creation of a spatial database of the protected areas in Punta del Este Isla de la Juventud. Cuba.
- Biophysical characterization of the Mangrove ecosystem in the protected area Punta del Este Isla de la Juventud. Cuba.
- Determination of the current state of the strips hydro-regulators in the half section of the basin of the Guamá River Pinar del Río. Cuba.
- System of measures for the recovery of stagnant and degraded Mangrove Forest of the Cuyaguateje River. Cuba.
- Proposed management for the Arboretum of Taironas. Pinar del Río. Cuba
- The application of Linear Programming in Forest Engineering.
- Contamination of Mangrove by Hydrocarbons and restoration strategies. Pinar del Río. Cuba
- Proposal for the ordination of the trees found outside of the forest in the northeast section of the Guamá River Pinar del Río. Cuba.

Amberly R. Moon

Biodiversity Specialist

Amberly has over 12 years of professional experience that includes project management, assessing biological impacts, conducting baseline studies and habitat assessments, surveys for threatened and endangered species, and environmental permitting. As an environmental consultant, her primary focus has been on the oil and gas and mining sectors, with additional experience in the power and transmission sector. She has assisted in preparation and review of environmental, social, and health impact assessments in North and South America. Amberly has supported projects for EEPGL since late 2018. She has managed EA&MPs for proposed exploratory drilling campaigns in offshore Guyana, and assisted in preparing EMPs, EIAs, and supplemental EIAs.

Experience: 12 years' experience including mining, oil and gas, power, and government.

Key Projects

EIA for Off-shore Drilling and Production, Guyana 2019
Authored the introduction, administrative framework, and cumulative impacts for an offshore oil and gas EIA. Developed a traffic impact analysis data sheet and potential traffic routes for vehicles related to the project. Assisted in managing client comments and implementing changes including embedded controls, mitigation measures, and monitoring measures for the physical, biological, and social resource sections. Created presentations for the Guyana EPA and posters for the public describing the project.

EA&MP for Off-shore Exploration Drilling, Guyana 2020
Managed the production of an Environmental Assessment and Management Plan for an offshore exploration drilling project including existing conditions and impact assessment for physical, biological, and social resources, and cumulative impact analysis.

EA&MP for Off-shore Exploration Drilling, Guyana 2019
Managed the production of an Environmental Assessment and Management Plan for an offshore exploration drilling project including existing conditions and impact assessment for physical, biological, and social resources, and cumulative impact analysis.

Supplemental EIAs for Two Off-shore Drilling FPSOs, Guyana 2019
Managed the production of two addendum EIAs for two FPSOs based on input from the Department of Energy. The supplemental EIAs included updates to the Development Plan, definitions of magnitude and sensitivity, descriptions of Best Available Technologies, alternatives for treatment and disposal of produced water, analyzing impacts from greenhouse gas emissions, and updates to the Environmental and Socioeconomic Management Plan, Waste Management Plan, Decommissioning Plan, and Oil Spill Response Plan.

EMP for Off-shore Exploration Drilling, Guyana 2019
Assisted in managing team in writing an Environmental Management Plan for an offshore exploration drilling project. Authored the existing conditions and impact assessment sections for special status species and protected areas.

Technical Review for ESIA, Columbia
Managed a large team to provide a technical review of an ESIA for a mining site in Columbia. The review included revisions to proper English from its original Spanish translation.

Permitting and Environmental Surveys for a Pipeline, Wyoming & Colorado
Assisted in regulatory permitting with U.S. Army Corps of Engineers, Wyoming state permitting, and Colorado local county permitting. T&E species lead and coordinator for MOCs in Wyoming and Colorado. Authored species memos for burrowing owls and raptors, and coordinated with state agencies to discuss recommendations for state T&E species. Conducted surveys for burrowing owls.

SEIS for Transmission Line Project for a Large Pipeline, Montana, South Dakota, and Nebraska
Wrote the water resources section in a draft SEIS for a large crude oil pipeline crossing three states. The SEIS project is for the transmission and distribution lines and substations connecting to the pipeline.

Exploration Drilling EA, Arizona
Completed a preliminary data adequacy review of the client's survey data to determine data gaps or needs for the Section 7 consultation process. Served as project coordinator by maintaining the administrative record, authoring meeting notes, RFAIs, monitoring the project schedule, and scheduling meetings with USFS. Developed an administrative record index, RFAI tracking spreadsheet, and QC of the author

templates. Project management activities include cost monitoring, budgeting, invoicing, and preparing monthly progress reports.

Annual Greater Sage-grouse Lek Survey, Nevada
Managed the project from 2018 through 2020 including staff, schedule and survey logistics, protocols, cost monitoring, budgeting, invoicing, and quality control of collected data in Survey123. Conducted Greater sage-grouse lek surveys and habitat reconnaissance using the Nevada Department of Wildlife (NDOW) protocol, Survey123, and ArcGIS Collector. Analyzed the collected data and completed a final technical review of all survey reports. Built a strong working relationship with NDOW that has aided in opening the doors of communication and allowed flexibility in protocols to ensure better data collection at lek sites.

Greater Sage-grouse Lek Survey, Nevada
Managed a new sage-grouse survey program for a mine in the Battle Mountain range of Nevada, including development of the program, coordination with NDOW, survey logistics, cost monitoring, and cloud-based data collection in Survey123.

Biological Baseline Studies for a Legacy Uranium Mine, New Mexico
Managed and authored the Phase I Environmental Report associated with a legacy uranium mine site to support future compliance with NEPA. Conducted migratory and breeding bird surveys along transects at 300 m intervals as part of the Phase II Environmental studies. Completed a desktop assessment of habitats to digitize transects for the surveys and develop the survey protocol and forms using ArcGIS Collector and Survey123. Analyzed the collected data to author the final Phase II report. Created maps for the report using ArcGIS. Completed project management duties including field scheduling, Level 3 HASP compliance, cost monitoring, budgeting, and oversight of subcontractors.

Biological Baseline Studies for a Mining Site, Nevada
Managed the project including staff, schedule, survey logistics, subcontractor, protocols, budgeting, and invoicing. Performed a desktop assessment prior to field work to establish survey transects in locations of suitable habitat. Conducted surveys for migratory and breeding birds, burrowing owls, and pygmy rabbits following BLM protocols. Determined appropriate sites for deployment of a bat acoustic monitor. Processed all collected data for analysis and authoring the final Biological Baseline Report.

Sage-grouse Mitigation Program, Nevada
Managed and authored the first agency Annual Report containing implementation data for activities performed to restore habitat for greater sage-grouse as part of a Bank Enabling Agreement (BEA) between the client and Bureau of Land Management (BLM). Analyzed annual monitoring data to create implementation data sheets to present to BLM. Project management activities include budgeting and invoicing.

Kangaroo Mouse Survey at a Mining Site, Nevada
Performed a desktop assessment prior to field work to determine areas of suitable habitat in a leach pad expansion area for the dark and pale kangaroo mouse. Managed the field staff who conducted the survey, analyzed data collected in the field, and authored the final survey report.

Biological Baseline Report for a Mining Site, Nevada
Provided technical authoring and editing for the 2017 Biological Baseline Report containing 5 years of collected data to support future NEPA compliance. Compiled data from the survey years to create final report tables and appendices. Implemented BLM comments and prepared responses. Performed quality control of presented data and figures, and assumed project management duties including invoicing, budgeting, and cost monitoring.

Wildlife Impact Assessment for a Mining Site, South Carolina
Authored a wildlife impact assessment including using existing data from previous baseline surveys. Project management duties included budget and schedule oversight, and review of authored reports and data.

Cyanide Audit for a Mining Site, South Carolina
Project manager for cyanide code audit to ensure client is ready for an audit. Provided project oversight to ensure gaps were being addressed on-site, all ERM and client H&S measures are being followed, and management of the budget and schedule.

Burrowing Owl Surveys for a Pipeline, Wyoming
Conducted burrowing owl surveys as a lone-worker along a pipeline ROW to confirm presence/absence of species in accordance with state requirements. Validated the Environmentally Sensitive Areas (ESA) established to protect the burrowing owls.

Emergency Permitting for Wildfire Rapid Response EP, Environmental Coordinator, and Business Unit Staff Coordinator, California
Wrote biological permits for an emergency response project along an existing transmission line in Northern California. Permits were written to agencies including USFS and BLM. Managed biological monitors on daily surveys and data collection. Coordinated and vetted staff from the Mountain West Business Unit for long-term deployment to the project site.

Bald Eagle Survey for Pipeline ROW, West Virginia
Performed aerial bald eagle nest surveys via helicopter in Monongahela National Forest for existing pipeline constructions. Compiled the collected data and edited the final survey report.

CURRICULUM VITAE

Mark Ram
University of Guyana: Biodiversity Specialist

Education	PG Dip (2019) Higher Education, University of Guyana, Guyana MSc (2018) Forest Biology, University Guyana, Guyana. BSc (2016) Biology, University of Guyana, Guyana.
Current Position	Lecturer, Department of Biology, University of Guyana.
Office Address	D5 Department of Biology, University of Guyana.
Contact Information	
– **telephone:**	+1 592-611-9927
– **email:**	mark.ram92@yahoo.com mark.ram@oug.edu.gy
– **website:**	http://fns.uog.edu.gy/staff/mr-mark-ram

Research Interests	Marine Ecology, Marine Conservation Science, Coastal ecosystems, Oceanography, Forestry, Climate Change, Habitat Degradation and Restoration.

Professional Experience	April 2019– Present: **University of Guyana** **Student Internship Coordinator** Main duties: Responsible for the selection, placement and supervision of interns in the Department of Biology. April 2017– Present: **University of Guyana** **Scientific Officer/Assistant Lecturer** Main duties: Aid in the delivery of course content to undergraduate students, co-supervise undergraduate research projects, involved in the day to day management of a museum and herbarium, verification of biodiversity specimens and samples for export and individual research. September 2016 – June 2017 **University of Guyana** **Laboratory Demonstrator (part-time)** Main duties: Supervision of laboratory exercise, graded and recorded marks for lab assessment and aid in designing practical field exercise.
Publication In-preparation	(1) Fish community composition after mangrove restoration along the Northern Atlantic Coast of Guyana. (2) Regeneration of *Chlorocardium rodiei* (greenheart) in logged and unlogged forest in Guyana
Professional Courses & Training	• Forest Landscape Restoration • Quantitative Analysis of Ecological Data • Qualitative Research Methods • Forest Research Methods • Ocean Governance-University of Sao Paulo • Tropical Coastal Ecosystems • Wildlife Survey Techniques • Disasters Environment Risk Reduction • Life on Earth: Biomes, Climates, Ecology and Evolution • Scientific Writing • Principles of Biochemistry • Ecological Monitoring • Species Conservation • Field Guide Preparation

CURRICULUM VITAE

Teaching Experience

University of Guyana-Department of Biology

Instructor (Undergraduate Courses)

- Marine & Coastal Ecology
- Biology of Marine Organisms
- Coastal Zone Management
- Ecology and Environmental Biology
- Biometry & Biostatistics
- Introduction to the Biology and Ecology of Living Organisms
- Conservation & Management of Forest Ecosystems
- Laboratory Instructor (2016-2017) for the following courses: Introductory Biology, Ecology, Biochemistry, Parasitology, Animal Physiology, Biotechnology, Microbiology, Plant Ecology, Taxonomy& Systematics, Vertebrate Zoology, Biology of Animals and Biology of Plants.

Instructor (workshops)

- Data Analysis in R (2018) Centre for the Study of Biodiversity, University of Guyana.

Research and Fieldwork

- Impacts of mangrove habitat degradation on fish community structure along Guyana's coastal regions (2018) MSc. Thesis.
- Socio-Economic Survey and Length-Based Stock Assessment Guyana and Suriname (2017-2018) for WWF Guianas.
- Regeneration of *Chlorocardium rodiei* (greenheart) in logged and unlogged forest in Guyana
- Survey of ecotourism resources and aquatic and terrestrial ecosystems of Orinduik falls and the upper Ireng river drainage, Region 8, Guyana (2016) led by Dr. Nathan Lujan
- Assessment Sharks & Rays Diversity of the North Atlantic Ocean, Guyana (2016) led Elford Liverpool
- Stream quality assessment and mercury content analysis using fishes and macroinvertebrates at Cuyuini Guyana (2015) led by Mr. Elford Liverpool.
- Comparison of avian and fish diversity in disturbed and undisturbed mangrove ecosystem (2015) led by Kavita Dookram.
- Effect of changing climatic variables on butterflies at CEIBA Biological Centre (2016). BSc. Thesis.

Talks

- Wetlands in Guyana (2019) Biology Club at the University of Guyana

Awards & Grants

- World Wildlife Fund- Education for Nature Professional Development Grant (2019)
- Conservation Leadership Progamme. Population dynamics of *Chlorocardium rodiei* (Greenheart) in Guyana, South America (2019).
- UG-UF (NORAD/WWF-Guianas). Achieving a Green State: Building human capacity for natural resource management in Guyana (2018)
- National Agriculture Research and Extension Institute, Guyana Mangrove Restoration Project small Grant (2017)

Posters and presentations

- Distribution, abundance & types of plastics debris along selected beaches in Guyana. Gulf & Caribbean Fisheries Institute 72nd Conference (2019) Punta Cana, Dominica Republic.
- Impacts of mangrove habitat degradation on fish community structure along Guyana's coastal regions. National Agriculture Research & Extension Institute Research Conference (2018), Guyana.

- Impacts of mangrove habitat degradation on fish community structure along Guyana's coastal regions. Latin America Caribbean Conference for Conservation Biology (2018) University of West Indies, Trinidad.
- Impacts of climate change on farmers and their adaptive strategies along the Essequibo Coast, Guyana. Latin America Caribbean Conference for Conservation Biology (2018) University of West Indies, Trinidad.
- Impacts of mangrove habitat degradation on fish community structure along Guyana's coastal regions. Sao Paulo School of Advanced Science on Ocean Interdisciplinary Research and Governance. (2018) University of Sao Paulo, Brazil.
- Regeneration of *Chlorocardium rodiei* (greenheart) in logged and unlogged forest in Guyana. The University of Guyana and The University of Florida in collaboration with WWF launch NORAD Funded Partnership, Guyana.

Consultancies

- Barima-Mora Passage Mangrove Special Protected Area (2019) Landel Mills International
- Coastal Sensitivity Mapping for Oil Spill Response in Guyana (2019) for Pragmatics Inc.
- Fishes of the Nappi Water Catchment Area, Nappi Village, Rupununi, Region 9 (2019). Conservation International Guyana.
- Identification of Marine Deepwater Specimens (Macro-Invertebrates and Fishes) (2018) Environmental Resource Management.
- Survey of mangrove fishes at Hope, Guyana. (2018). The Conservation Leadership in the Caribbean.

Associations

- Society for Conservation Biology
- Global Youth Biodiversity Network
- University of Guyana Biology Club
- Caribbean Youth Environment Network Guyana

Supervision of undergraduate Research Projects

- Brea Aaron (2019). Assessment of Crustaceans abundance and diversity in different mangrove ecosystems in Demerara-Mahaica (Region 4), Guyana.
- Waynace Forde (2019). The distribution, abundance, and characteristics of Marine debris along beaches in Demerara-Mahaica (Region 4), Guyana.
- Daniella Decosta (2019). Distribution, Composition and Abundance of fishes from the Moruca river (Region 1), Guyana.
- Jaishri Jethu (2019). A partial baseline study of the Butterfly Diversity within the Biodiversity Gardens of the Botanical Gardens, Georgetown, Guyana.
- Joanna Porte (2018) Impacts of water quality on fish diversity, richness and abundance in mining-impacted and non-mining impacted sites at Kaieteur National Park.
- Rovindra Lakenarine (2018) Impacts of climate change on farmers and their adaptive strategies along the Essequibo Coast, Guyana.

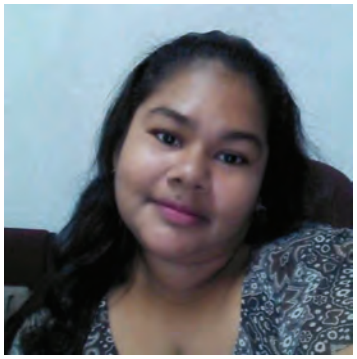
Indranee Roopsind

Leon Moore Nature Experience: Biodiversity Specialist

Indranee is a Guyanese field biologist who has conducted field expeditions all over Guyana studying large and small mammals with special focus on riverine and semi-aquatic specie, reptiles and amphibians, birds, and fishes. She has worked on developing and implementing monitoring systems for wildlife management, and wetland systems within the Iwokrama Forest and the North Rupununi Wetlands. She has a keen interest in understanding the population and behavioral ecology of the Giant River Otter Pteronura brasiliensis in Guyana. Over the years, she has also worked extensively with indigenous peoples on strategies that link the science of traditional knowledge with strategies for natural resources management. In the last year, she worked as part of a team with ERM Guyana for the EEPGL Guyana to develop and implement surveys for riverine mammals in the Demerara River.



Experience: 20 years of experience in environmental education, biodiversity assessments and working with indigenous communities on natural resource management planning

Email: Indranee.Roopsind@erm.com

Education

- Bachelors of Science, Biology Major, Chemistry Minor, 2002, University of Guyana
- Master of Science, Forest Biology, UG (Ongoing)

Professional Affiliations and Registrations

- IUCN SSC Otter Specialist Group (Giant Otter Species Group)
- Women in Nature Network (WiNN)Guyana

Languages

- English

Fields of Competence

- Field biology (Mammalogy, Herpetology and Ichthyology)
- Community engagement
- Environmental education

Key Industry Sectors

- Biodiversity
- Wetland ecology
- Ecosystem services and sustainable development

Honors and Awards

- Cleveland Metro Parks Zoo Scotts Neotropical Fund.
- Tom Dolan IV Conservation Fellowship. 2003. Philadelphia Zoo, USA
- UNDP Volunteer Award.
- Grant from the Smithsonian National Zoo. 2001
- Grant from the Jacksonville Zoo. 2001

Key Projects

Demerara River Mammal Survey (2019-2020) ERM Guyana
Main Duties: Assist in the development of survey methodology, implementation of survey and compilation of final report**.**

Community Engagement Specialist/Field Manager (2016 – 2018) WWF Guianas
Main Duties: Facilitate training and development sessions for indigenous villages in Region 9 on the development of 10 year village improvement plans, and coordinate field activities in the Rupununi.

Research Assistant (April 2015 – 2016) PANTHERA
Assessing sustainable hunting yields and hunter awareness as a foundation for managing wildlife populations in Guyana.

Rapid Assessment Programme Researcher (June 2014 – September 2014) Conservation International
Responsible for the documentation of the levels of ecosystem services use by communities and potential impacts on the savanna/forest/wetland systems for the baseline assessment for the expansion of the pre-investment Georgetown-Lethem Road.

Biodiversity specialist (August 2012 – October 2012)
Responsibilities included the design, implementation and compilation of an assessment of the biodiversity along the Cove and John Mangrove Reserve for applications to the Guyana Mangrove Restoration Project.

Researcher/Lecturer (August 2009 – October 2011)
IUCN funded project working with indigenous communities in southern Guyana (Rupununi) on capacity enhancement and natural resources management planning associated with wetland resources, including community fisheries management, and natural sites management. Work included facilitating courses to youths from Amerindian communities in the Rupununi, aimed at wildlife and natural resources management.

Research Assistant/Wetlands Researcher (January 2004 – December 2008)
Darwin Initiative sponsored project; Sustainable Management of the Rupununi Wetlands – Linking People, Environment and Biodiversity; Phase 1 and Phase 2.

Research Assistant
Development and implementation of distribution and habitat use studies of P. brasiliensis in the Iwokrama Forest and North Rupununi Wetlands. Additional responsibilities included extensive faunal field surveys, river patrols, data entry, and community outreach.

Environmental Educator
Responsibilities include the preparation of a bi-annual newsletter, instructing classes at the Guyana Zoo to primary level.

Leanna Kalicharan
University of Guyana: Marine Science Specialist

lkalicharan@yahoo.com | skype: leanna.kalicharan | +592 - 688 - 1733 | Lot 42 Annandale West E.C.D | DOB: 25/12/1990

EDUCATION

Master of Arts: Education (Leadership). In progress **2019 – 2021**
University of Bedfordshire (UB), United Kingdom

Post Graduate Diploma in Education: Higher Education. Pass with Distinction **2017 – 2018**
University of Guyana (UG), Turkeyen Campus, Georgetown, Guyana

Master of Science: Nat. Resource & Environ. Mgmt.: Coastal & Marine Resource Management **2015 – 2017**
University of the West Indies (UWI), Cave Hill Campus, Saint Michael, Barbados

Bachelor of Science: Biology. Pass with Distinction **2009 – 2013**
University of Guyana (UG), Turkeyen Campus, Georgetown, Guyana

EXPERIENCES

Consultant. CARIBBEAN REGIONAL FISHERIES MECHANSIM (CRFM), GY/SVG **3 – 4/2021**
Independently reviewed Guyana's fisheries laws, policies and plans, and consulted with the Officers of the Guyana Fisheries Division and artisanal fisherfolk to develop a detailed report and Communication Strategy Action Plan to improve effective communication of key fisheries laws, policies and plans between the Fisheries Division and fisherfolk in Guyana.

Consultant. OMAI GOLD MINES, Cuyuni-Mazaruni, GY **1 – 3/2021**
Conducted an Environmental Baseline Study (EBS) to develop a detailed report that described vegetation and wildlife biodiversity (terrestrial and aquatic), surface water and sediment quality that can be potentially affected by mining exploration.

Consultant. PRAGMATIS INC., GY **7 – 8/2019**
Conducted an Environmental Sensitivity Mapping (ESM) of Guyana's Coastal Zone to develop a detailed report, which characterized sensitive coastal and marine environmental and socioeconomic resources that can be potentially exposed and affected by the oil and gas industry.

Consultant. Guyana Society for Biodiversity and Ecosystems (GSBE), GY **7 – 8/2017**
Independently reviewed literature and conducted interviews with key stakeholder agencies involved in the water sector to prepare a detailed report and subsequently presented at a public forum on the status of Guyana's Freshwater Ecosystems.

Lecture I. University of Guyana, Faculty of Natural Sciences, Department of Biology **10/2016 to present**
Core Subject Areas: Introductory Biology, Introductory Microbiology, Biochemistry, Ecology, Environmental Biology, and Natural Resources & Environmental Management.

Assistant Lecturer. University of Guyana, Faculty of Natural Sciences, Department of Biology **3 – 7/2015**
Independently delivered 3 third year courses to undergraduate Biology majors in one semester by planning and organizing each course lectures, laboratory exercises, assignments, and examinations.

Field Research Assistant. Guyana Gold Fields Inc., Cuyuni-Mazaruni, GY **6/2015**
Collected and catalogued freshwater fish species, macro-invertebrates, sediment, and water samples for assessment of mercury content, culminating to an analytical report with recommendations for the improved management of mercury usage on site.

Tutor. University of Guyana, Faculty of Natural Sciences, Department of Biology **9/2012 – 12/2014**
Supervised at least 10 hours of laboratory sessions weekly over 6 semesters by introducing and demonstrating lab exercises to up to 60+ undergraduate students, while ensuring each activity was conducted in an orderly and safe manner.

Field Research Assistant. World Wildlife Funds Guianas/Global Wildlife Conservation, GY **9 – 10/2014**
Collected and documented freshwater fish species from the South Central region of Guyana with 3 other team members. Assisted with the scientific tagging of the collected specimens, and technical collection & storage of fish tissue for DNA, mercury and isotope analyses. Contributed to data analyses and subsequent preparation of the preliminary survey report.

Field Research Assistant. Arapaima Research Project, Shedd Aquarium/Rewa, GY **3/2014**
Assisted the principal researcher with the capturing of arapaima for surgical implantation of radio transmitters and tracking of arapaima in the Rewa River to map their migration patterns.

Field Research Assistant. Black Caiman Research Project, Yale University/Yupukari, GY **2/2014**
Captured and processed large (10+ feet) caimans to assess their morphological features and kept the Caiman Capture Database updated and organised. Assisted with stomach pumping of caimans to determine their feeding habits by identifying prey items collected from stomach contents. Collected caimans blood samples and prepared them for stable isotope analysis.

Field Research Assistant. World Wildlife Funds Guianas/Global Wildlife Conservation, GY **10 – 11/2013**
Collected and documented freshwater fish species from the South Rupununi region of Guyana. Assisted with the scientific tagging of the specimens, and technical collection and storage of fish tissue for DNA analyses.

EXPERIENCES

Summer Intern. Environmental Protection Agency Guyana (EPA), Georgetown, GY **6 – 9/2013**

Interned full-time as an Assistant to National Biodiversity Strategy Action Plan (NBSAP) Project Manager and conducted field surveys with the Environmental Management Division to produce detailed reports from one-on-one interviews done with the citizens on environmental compliance.

Enumerator. Guyana Bureau of Statistics, Georgetown, GY **9 – 11/2012**

Conducted at least 800+ structured interviews with civil servants to obtain census data through verbal communication, and prepared weekly progress reports on the status of work.

Field Research Assistant. Neotropical white-sand forest Research, Mabura, GY **8/2012**

Assisted the principal researcher to collect and identify local plants species, and prepared specimens for DNA analysis.

Field Research Assistant. **Aquatic Biodiversity & Water Quality Surveys, Shedd Aquarium/Karanambu, GY** **3/2012**

Collected and documented fish species to assess their health by preparing blood smears for evaluation and assessed water quality.

ACTIVITIES

N**etwork Coordinator** (Caribbean). United Nations Sustainable Development Solutions Network (SDSN) – Youth 12/2016 to 02/2021

Regional Coordinator (Caribbean & the Americas). Commonwealth Youth Climate Change Network (CYCN) 7/2016 – 7/2018

Recipient. Dean's Honour Roll Award for outstanding scholastic performance in PGDip Programme. 12/2018

Special Envoy. Caribbean Youth Environment Network (CYEN) 7/2016 – 7/2018

Recipient. National Youth Awards. Award of Service in recognition for championing Environmental Awareness and Biodiversity both as a Volunteer and Lecturer at the University of Guyana. 11/2017

Awardee. Best Graduating Student of Class 2013 – Department of Biology, University of Guyana 10/2013

Recipient. The Harry Persaud Memorial Prize for highest grade in taxonomy course – University of Guyana 9/2013

Mentee. Commonwealth Women's Mentorship Scheme 7 – 12/2017

Participant. University of Guyana (CSBD) – *Statistical Methods for Data Analysis in R (Workshop)* 10/2018

Country Participant. UNESCO, Port of Spain, Trinidad and Tobago – *Sandwatch: Citizen Science Workshop* 10/2017

Participant. Guyana National Youth Council, Georgetown, Guyana – *Effective Conflict Management, (Workshop)* 2/2015

Participant. Guyana National Youth Council, Georgetown, Guyana – *Grant Writing & Fundraising, (Workshop)* 1/2015

Participant. Global Shapers Community Hub, Georgetown, Guyana – *Communications Workshop, (Certificate)* 11/2014

Participant. Panthera/University of Guyana – *Tools for Conservation: Monitoring with camera traps, (Certificate)* 2/2014

Country Participant. Green Heritage Funds Suriname, Paramaribo, Suriname – *Diversity, Conservation and Research of Xenarthra*, (*Certificate)* 2/2013

Mark Irvine

Physical Oceanographic Specialist

Mark Irvine is a Technical Director in ERM's Impact Assessment and Planning team and is based in Edinburgh. Mark has been working in environmental consultancy for 28 years in which time has carried out numerous desk- and field-based projects covering a wide range of environmental and social issues as part of ESHIAs, ESM, monitoring plans and related studies. These projects have included terrestrial, coastal, and marine surveys covering physical, biological, chemical, and socio-economic impacts from development projects (including habitat mapping and ground truthing, fish and fisheries studies, seabed and water quality monitoring and socio-economic baseline studies).

Experience: Mark has wide experience in managing large and complex projects (fee value ranging from £0.5 to £1 million), and working with a wide range of specialists from within ERM and sub-contracted companies. Project work has often included large scale consultation and communication programmes with government and other regulatory bodies, local stakeholders and the wider public. Mark has worked primarily on projects in the oil and gas, ports and harbours, marine dredging and disposal, water, and offshore windpower industries. Mark's international experience includes working in Algeria, Azerbaijan, Brunei, Ethiopia, Ghana, Kenya, Libya, Nepal, Nigeria, Qatar, Russia (Sakhalin Island), Turkey, Turkmenistan and Uganda. Recent international projects have included ESHIAs, EMPs and associated consent submissions for the Jubilee and TEN developments in Ghana, and ESHIAs for oil and gas exploration activities in Ethiopia, Kenya, and Uganda.

Education

- MSc Water Resource Management (Distinction). Edinburgh Napier University, 1993
- BSc (Hons) Zoology, Class IIi. University of Aberdeen, 1984

Professional Affiliations and Registrations

- Member of the Institute of Environmental Management and Assessment

Fields of Competence

- Environmental Social, Health Impact Assessment (ESHIA);
- Environmental Auditing;
- consenting, licensing and planning;
- impacts of onshore and offshore oil and gas developments;
- impacts of marine and coastal zone developments on marine sediments and water quality;
- design and management of marine and aquatic monitoring surveys;
- fish and fisheries studies;
- liaison at all levels with clients, research establishments, central government departments, local authorities and non-governmental organisations;
- public communication and consultation;
- Expert Witness on EIA process and marine impact issues at two Public Inquiries.

Key Projects

Environmental and Social Support to the Nord Stream 2 Pipeline Project. Nord Stream. 2016-2017. ERM have been retained to provide environmental and social support to the Nord Stream 2 Project Team on a range of terrestrial and marine issues related to the NSP2 project, in particular in relation to IFC Performance Standards. Mark leads on providing advice on marine issues, including assessment of physical, chemical, and biological impacts from pipeline installation and landfall construction.

Operations Permit Support for the development of the Tweneboa, Enyenra, Ntomme (TEN) fields, Deepwater Tano Block, offshore Ghana, Tullow Oil, 2014-2017. Mark is the ERM project manager for the development of a series of management plans and procedures to implement the ESHIA and IFC Action Plan commitments for the TEN project. These include environmental management and monitoring plans, commissioning and decommissioning plans, waste management plan, and local content and social performance plans.

Independent Monitoring Group for compliance with IFC Performance Standards for Kenya and Ethiopia Oil and Gas Exploration and Development Projects Africa Oil Corp, 2015-ongoing. Mark is the team leader for the Independent Monitoring Group with respect to Africa Oil Corporation's compliance with the IFC Performance Standard for their interests in Kenya and Ethiopia. ERM is undertaking six-monthly monitoring visits which commenced in December 2015.

Best Practicable Environmental Option (BPEO) Studies for various clients, 1999-2017. ERM undertook a series of BPEO studies in support of licence applications for dredging and dredge spoil disposal. Habitats Regulations assessments were also undertaken to identify any potential issues with respect to European designated sites such as the Forth Islands SPA. Twenty-three separate BPEO studies have now been undertaken in the Firth of Forth and Tay Estuary.

Environmental Impact Assessment for Beatrice Offshore Wind Farm. Beatrice Offshore Windfarm Ltd, 2010- 2013. Mark was the Technical Director for the EIA for a 980 MW, 190 turbine offshore wind farm in the Moray Firth. Baseline studies include, coastal processes, seabirds, marine mammals, benthos, archaeology, shipping and navigation and aviation.

Environmental Assessment of Proposed Aggregate Dredging Operation, Liverpool Bay, Westminster Gravel Ltd, 1999 -2014. ERM was commissioned to conduct an EA for an offshore aggregate production licence in Liverpool Bay. A marine survey was carried out by ERM in 2001 and the Environmental Statement (ES) and Supplementary ES were issued. Ongoing monitoring support was provided during the licence period.

Area 351, area 340 and Area 451 Aggregate Production Licence Applications, Isle of Wight, Northwood (Fareham) Ltd, Westminster Gravels Ltd and Cemex Ltd, 2007 –2013. Mark was Project Director for three EIAs for licence renewal applications east of the Isle of Wight. Key issues are coastal impacts, navigation, archaeology, fishing activities and cumulative impacts from other dredging and dumping sites in the area.

Environmental Management Support for Jubilee Field Phase 1 Development, Tullow Ghana Ltd, 2010-2016. Mark was the Technical Director for a series of projects to provide support to Tullow Ghana Ltd to meet its permit requirements. These have included Waste Management Plan; Marine, Air Quality and Noise Monitoring Procedures; and a Fish and Fisheries Study.

Environmental Impact Assessment for Port of Mostyn: Maintenance of Navigation, 2006 - 2009. Mark was the Project Director for an EIA for capital and maintenance dredging of the navigation channel at the Port of Mostyn to further develop the port to allow it to receive large cargo vessels, including handing the wing sections for the Airbus 380. The Dee Estuary is designated as an SPA, SSSI, and RAMSAR site and the proposed development requires an Appropriate Assessment under the Habitat Regulations.

Environmental Impact Assessment of Proposed Aggregate Dredging Operation, Nobel Banks, Llanelli Sand Dredging, 2001- ongoing. ERM was commissioned to undertake an EIA for a new licence on Nobel Banks, off the Gower Peninsula (South Wales). Mark was the ERM Project Director and appeared as an Expert witness at a Public Inquiry in 2005. A licence was awarded for Nobel Banks in 2005. ERM continued to support LSDL in designing and interpretation of monitoring surveys during the licence period.

Environmental Monitoring of Clearance Operations in Holy Loch, MOD(N), 1997 - 2002. ERM was commissioned to undertake a major programme of field investigations to monitor the effect of the four year programme of debris clearance operations following the use of Holy Loch as a submarine maintenance depot. The monitoring programme covered water quality, sediment chemistry, ecotoxicology, bioaccumulation, radiation levels, and noise monitoring.

Environmental Assessment for CCGT Power Station. Intergen-Enka, Turkey 1999. ERM was commissioned by Intergen-Enka to carry out an Environmental Impact Assessment for a proposed 1500 MW CCGT power station near Izmir in south-west Turkey. The assessment was required to be carried out to World Bank standards. Mark's role was as survey manager working with consultants based in Turkey to produce an assessment of impacts of the cooling water intake and thermal discharge on the marine ecology of Nemrut Bay.

Catriona Munro, BSc (Hons)

University of Guyana: Marine Science Specialist

Catriona Munro is a Senior Consultant in ERM's Capital Projects team in Edinburgh. Catriona has ten years experience gained through positions in industry, including offshore oil and gas sector, renewable energy, aggregates and dredging, port construction and conservation organisations. She also has good experience of technical reporting and data quality control.

Her work has involved interaction with a variety of personnel within regulatory and licensing bodies, local stakeholders and the general public.

Catriona has primarily worked in the UK and Channel Islands, with experience of working on a wide range of projects in the North Sea, Atlantic Ocean, South China Sea, West African and Norwegian waters.

Experience: 10 years' experience in marine environmental surveying and consulting

Email: Catriona.munro@erm.com

LinkedIn: https://www.linkedin.com/in/catriona-munro-5798583b/

Education

- Applied Marine Biology, BSc (Hons). Heriot Watt University, UK, 2008

Languages

- English, native speaker

Fields of Competence

Catriona's experience covers a broad range of topics in environmental assessment. These include the following areas of work:

- Planning and managing marine and aquatic monitoring surveys.
- All aspects of marine environmental surveying, with particular expertise in acquiring high definition video and stills and accurate positioning.
- Consenting, licensing and planning (including preparing all Health and Safety documentation).
- Project Management.

Key Industry Sectors

- Ports and marine infrastructure
- Aggregates
- Oil and gas
- Marine renewable energy
- Unconventional power

Qualifications and Certificates

- Basic Offshore Safety Induction and Emergency Training (BOSIET).
- Offshore Medical ENG1.
- ISOS Fit to Work certification.
- Open Water PADI.
- Helicopter Underwater Escape Training (HUET).
- Travel Safely by Boat (OPITO).

Key Projects

Key Community, Infrastructure and Transport Experience

Environmental Assessment and associated Permit Applications in support of a new telecommunications cable, USA to Norway/Denmark, Subcom, 2018. Author of the Environmental Assessment for submission to Marine Scotland in support of a Marine Licence application for a telecommunications cable crossing Scottish Territorial Seas. Role required multiple permit applications in three different countries.

Community Development Plan (CDP) in support of construction of a new fertiliser plant, Lekki Free Trade Zone Nigeria, Dangote, 2016-2017. Project manager for the CDP of 14 communities displaced due to the forceful purchase of their land. The CDP was a requirement of the International Finance Corporation (IFC) prior to the award of any funding. Role included organising logistics for in country sub-contractors, managing budgets, health and safety and reporting of findings from the field.

AP1, 2, 3 ,4 and 5 - High Speed 2 Phase 1 London-West Midlands: London Metropolitan and Country South - for HS2 Ltd, 2014-2015. Assistant to the planning lead for the additional provisions work organising the future baseline and cumulative assessment screening of new planning application and allocation records for the London and Country South routes since the HB ES Submission. ERM worked within a consortium with Temple Group and Mott MacDonald on the EIA of the High Speed 2 rail network proposed by the Government from London to West Midlands.

East Rail Phase 1 – for Network Rail 2012. Undertaking the noise scheme of assessment East Rail Phase 1 involves new track installation between Bicester and Oxford, and new/improved stations along the route. ERM has been working on the project from concept development to the opening of the railway.

Key Marine Aggregate, Mining and Port Experience

Best Practicable Environmental Option (BPEO) in Support of a Marine Licence, Leith, Rosyth and Dundee, Forth Ports 2017. Assistant project manager and survey coordinator for a BPEO study into the disposal of dredged material from the maintenance dredge at the Ports of Leith, Rosyth and Dundee. Currently supporting client throughout marine licence application process.

Marine support and compilation of a Construction Environmental Management Plan for Waterside Apartments, Gibraltar, Ocean Village, 2016. Project manager and technical advisor to the client in support of full planning application for an apartment development over water within a marina in Gibraltar. Careful planning to determine if a number of sensitive species are present within the project footprint required, involving liaising with divers, benthic surveyors, taxonomists and laboratories. CEMP currently under development for submission with full planning application.

BPEO in Support of a Marine Licence, Grangemouth and Methil, Forth Ports 2016. Assistant project manager and surveyor for a BPEO study into the disposal of dredged material from the maintenance dredge at the Port of Grangemouth and Methil Docks. Currently supporting client throughout marine licence application process.

MIDAS Deep Sea Mining, International, European Commission, 2015 – 2017. The MIDAS project is an EC funded 3 year multidisciplinary research programme into the environmental impacts of deep sea resource extraction. ERM formed one of the work packages for the project, tasked with describing the industry activities involved in deep-sea mineral extraction, identifying the main activities leading to impacts on the environment, defining environmental management practices to control these impacts, and

disseminating this information to the other MIDAS work packages. ERM undertook engagement with industry stakeholders to define likely activities, and develop mining scenarios for assessment. Catriona wrote a number of deliverables for ERM's work package. Catriona also contributed to a review of standards and guidelines relevant to the environmental management of deep sea mining projects.

BPEO in Support of a Marine Licence, Newhaven, Forth Ports 2016. Project manager for a BPEO study into the disposal of dredged material from the maintenance dredge at Newhaven Harbour. Supported client throughout marine licence application process.

Five Year Monitoring Review, dredging operations at Area 457, Liverpool Bay, England, Westminster Gravels Ltd, 2015-2016. Primary author of the monitoring review of the five year monitoring review of dredging operations at Area 457. Role involved drawing on information provided from three site specific studies from different subcontractors to inform the assessment.

Environmental Statement (ES) for the proposed aggregate dredging operation at Area 476, Bristol Channel, England, Llanelli Sand Dredging Ltd, 2014-2015. Assistant project manager. Role included undertaking the physical processes technical chapter, assessing the socio-economic effects and compiling the relevant policies and legislations and part of an EIA supporting a licence renewal application on Nobel Banks, off the Gower Peninsula (South Wales).

Environmental and Social Impact Assessment (ESIA) for a harbour development, Gibraltar, Government of Gibraltar, 2015. Author of the marine biology and physical processes chapters of the ESIA. Responsibilities included reviewing the information from the survey reports from a number of sub-contractors and incorporating the physical processes modelling report.

BPEO in Support of a Marine Licence, Kirkcaldy, Forth Ports 2015. Project manager for a BPEO study into the disposal of dredged material from Kirkcaldy Harbour.

BPEO in Support of a Marine Licence, Inverkeithing, Tarmac Lafarge, 2014-2015. Project manager for a BPEO study into the disposal of dredged material from Inverkeithing Bay. Study included the collection of a number of sediment samples using a hand corer for physico-chemical analysis.

BPEO in Support of a Marine Licence, Newhaven, Forth Ports Ltd, 2014-2015. Project manager for a BPEO study into the disposal of dredged material from the capital dredge of Newhaven Harbour. Study included overseeing subcontractors during the collection of a number of sediment samples for physico-chemical analysis using a vibrocorer.

Environmental Baseline Survey and ESIA, Sierra Leone, Confidential Client, 2014. Responsible for planning and undertaking the marine survey to provide information on sediment and benthic composition. Data is provided to fill data gaps, required to run hydrodynamic models on the proposed dredging works to deepen the existing port. Also responsible for the marine environmental chapter of the Scoping Report and subsequent ESIA for this major iron ore mine development in West Africa to IFC standards.

ES to support the renewal of licence Area 515, Humber, England, Westminster Gravel Ltd, 2014.
ES undertaken in support of an application for a Marine Licence to dredge aggregates, made to the Marine Management Organisation (MMO) under the Marine Works (Environmental Impact Assessment) (Amendment) Regulations 2011. Responsibilities included contributing to the scoping report and authoring the physical and biological chapters of the ES.

ESHIA for a port expansion, Kazakhstan, Chevron, 2012 – 2013. Working in a small marine and freshwater team to undertake the screening matrix, scoping report and marine associated chapters in ESHIA.

Key Oil and Gas and Unconventional Power Experience

Environmental Impact Assessment for the development of a new offshore gas pipeline, Equatorial Guinea, Noble Energy, 2018-2019. Reviewer of the drafted EIA and responsible for incorporating client comments into the main text. Further responsibilities included interpreting marine baseline data to include in the EIA following the revision of the first draft.

Consolidation of Baseline data from across 10 years in support of offshore gas field developments, Egypt, Exxon Mobil International, 2018. Author of the nearshore marine baseline chapter. Project required the consolidation of multiple years of data from two offshore gas fields owned and operated by different entities.

ESIA for offshore gas and liquid fields, PICO, Egypt, 2018. Co-author of the marine environmental assessment for the development of new offshore platforms and associated supporting infrastructure in a sensitive marine environment.

Scoping Report, Preliminary Environmental Information Report (PEIR) and ES for a Combined Cycle Gas Turbine (CCGT) Power Station and DCO application support, UK, Sembcorp, 2017. Assistant project manager coordinating a large technical team to pull together a scoping report, PEIR and ES in support of a DCO application. Alongside day to day management support, invoicing, programming and logistical organisation, responsibilities included drafting the socio-economic chapter of the scoping report and PEIR.

Critical Habitats Assessment and EIA review, Nordstream 2, Black Sea, 2016-2017. Development of a presentation to identify and present habitats identified throughout the Black Sea as critically endangered or endangered Project and the critical habitat. Technical review of some of the EIAs produced by other consultancies in support of the Project.

Marine Monitoring Plans for Burullus Power Station, Egypt, EEHC, 2016. Lead author of the marine monitoring plans for the construction and operation of the Burullus Power Station in Egypt. Monitoring plans followed national and international best practice and aligned with commitments detailed in the original ESIA.

Environmental and Social Impact Assessment (ESIA) for a proposed power plant, Ghana, Globaleq, 2015. Author of the marine baseline chapter focussing on the Project Area of Influence. Desk based review of data and interpretation of results from site specific physico-chemical and biological surveys.

Environmental Impact Assessment (EIA) screening report and supporting documentation for Planning and Flood Defence Consent applications, England, Client Confidential, 2015. Phase manager and coordinator for the EIA screening report for a new jetty into a river. The purpose of the jetty was to receive large building components for a nearby Carbon Capture and Storage plant. Role included authoring the EIA screening report and coordinating planning team, transport statement team and flood defence consent team in support of the planning application. Weekly update meetings held with client and various teams involved in the project.

EIA, HRA and Sustainability report for a Carbon Capture and Storage project, UK, Confidential Client, 2014 – 2015. Contribution to the marine environmental chapter within the EIA, identifying impacts as presented by modelling outputs.

Managing the marine plume modelling subcontractors. Maintaining open lines of communication between client Project Manager and own project team.

Environmental and Social Baseline Study for a Seismic survey, Caspian Sea, Confidential Client, 2014 – 2015. Desk based baseline data assimilation and presentation to provide an understanding of impacts of a 2D and 3D seismic survey. Responsible for the offshore chapters of the project.

EIA for onshore LNG plant in Tanzania, Statoil, 2014 – 2015. Undertaking the marine environment chapter for an EIA of a new LNG pipeline and onshore plant. Baseline data collation and subsequent assessment of impacts and risks of proposed development on the marine environment.

Production of offshore Marine Monitoring plans, Southstream Transport B.V. Bulgaria, 2014. Identifying potential receptors to planned pipeline works and providing monitoring plans during pre-construction, construction and operational phases to mitigate environmental risks of the project.

Southstream Gas Pipeline, Southstream Transport B.V. Bulgaria, 2014. Supporting SST B.V. in managing and reviewing the offshore (and landfall) Bulgarian section of this pipeline from Russia, across the Black Sea to Bulgaria as part of the wider Southstream project. Responsibilities include ongoing support to the post consent process including supporting production of project monitoring plans.

Shoreline Sensitivity Mapping, Firth of Forth to Peterhead, BP, September 2013 – 2014. Provision of marine technical expertise to create a comprehensive shoreline map of biological and socio-economic features. A sensitivity ranking was then assigned to gauge how sensitive an extensive stretch of shoreline would be to an oil spill from the Forties pipeline. Presented in GIS format.

EIA for the installation of cuttings cleaner units in Azerbaijan, BP, 2013. Contribution to a number of chapters within the EIA concerning proposed changes to the treatment of cuttings and possible consequent impacts to the surrounding environment. Mitigation of impacts identified to ensure compliance to internal and international standards.

Environmental Addendum and Technical Note for two drilling platforms in the Caspian Sea, BP, 2012 –2013. Study into the impacts of two drilling platforms on the surrounding marine environment. Potential impacts to a number of species were assessed, including the Caspian Seal. Mitigation measures were provided where necessary.

Preliminary ESHIA for a LNG development in eastern Africa, Client Confidential, 2012 –2013. Marine environmental specialist contributing to baseline studies and preliminary ESHIA marine chapters, aiding in gathering information for onshore site selection.

Key Renewables Experience

Scoping report and ESIA for a wind farm development, Ghana, EM Power, 2016-2017. Assistant project manager for a scoping report and ESIA of a small wind farm in Ghana. Responsibilities include logistics and coordination of teams in country during scoping and baseline field data collection trips. Co-author of environmental baseline and support to technical teams during ESIA.

Pre-scoping Report for the development of a tidal turbine barrage in North Wales, North Wales Tidal Energy, UK, 2016. Technical author for the pre-scoping report of the proposed tidal lagoon along the coast of North Wales. Report informed the Hendry Review, which was favourably received. Report presented in Word and Publisher format, making use of innovative infographics.

Topics authored included physical processes, metocean processes, sediment transport and coastal processes, marine mammals and terrestrial and coastal ecology.

ESIA for a Hydroelectric Dam, Sierra Leone, Joule Africa, 2016. Assistant project manager for an ESIA and survey support to teams in Sierra Leone. Role includes assisting the coordination of a team of over 20 surveyors in field in both the dry and wet seasons, addressing survey health and safety plans, managing logistics and organising import/export permits for samples. Co-author of a number of non-technical ESIA chapters.

Renewable Energy Projects EIA Process Review, UK Wind Power Projects, NEDO, 2015. Worked in a small team to review and collate up to date EIA policies and processed around onshore and offshore wind developments to inform the Japanese industry, where the EIA process is relatively long. An overview of typical environmental surveys, EIA process timeframes and procedures was provided to the client in support of streamlining the EIA process for wind power consent applications in Japan.

Baseline Habitat Mapping, Mull of Kintyre, RES, 2013. Lead environmental surveyor during a survey to recover underwater video footage of potential tidal device sites and cable landing options.

Other Selected Survey Experience

Deep Sea Site Investigation, South China Sea, BSP, 2013. Lead environmental scientist during a survey to recover deep water video and stills footage of potential and historic rig sites. Water profiling, sediment and water sampling also undertaken. Sediment and water collected for analysis of physico-chemical properties. Additional survey sites were undertaken investigating the potential for deep water coral reefs. Water depths ranged from 200 – 1200 m and data was collected using the DTS6000 deep water camera system, 0.25m^2 box core, Niskin water sampler and a Valeport multi-parameter water profiler.

Deep Sea Coral Habitat Mapping offshore Florida, PCCS, 2013. Identifying and mapping deep water corals along a 150 km proposed cable route corridor. Potential and probable coral areas identified from side scan sonar and multibeam echosounder data. Coral health and density assessed and recorded using drop down video and stills cameras. Advice provided where necessary on cable routing options to avoid areas of live coral.

Key Projects Prior to Joining ERM

Wave and tidal monitoring, SSE Renewables, Islay, 2012. Responsible for overseeing the deployment of three wave rider buoys, three guard buoys and an ADCP off the west coast of Islay as part of a data gathering exercise on the resource available to renewable energy at this site.

Current and tidal monitoring, SSE Renewables, Orkney, 2012. Lead environmental scientist on a number of current and tidal profiling surveys around the Orkneys. Involved developing new technology to work in extreme tidal races safely. Reporting included identification of any key species and habitats surrounding sites ear-marked for tidal turbine deployment.

Dredge plume monitoring, London Gateway, Thames, 2012. Characterisation monitoring of dredge plume involving following the dredger as it worked. A VMADCP was used to record suspended solids as backscatter, the data from which was input into Sediview to produce exact sediment plumes resulting from the dredger's excavations.

Water sampling, Sheerness Port Authority, Sheerness, 2011. Project manager on an extensive water and sediment sampling survey for a dredging licence. The survey also included the 30 day deployment of ADCPs to monitor current velocity and direction in the channel approaching the port. Responsibilities included liaising with the

Client and stakeholders, applying for licences and consents and managing survey teams and vessels.

Environmental baseline survey, Open Hydro, Northern Ireland, 2011. Project Manager. This study was conducted for a Client proposing to deploy an array of tidal turbines in a tidal race to the north east of Northern Ireland. A VMADCP and drop down video (DDV) survey were undertaken to determine the potential impacts of installing these devices in the proposed area, including potential cable landing sites. Responsibilities aside from Project Management included habitat mapping from DDV footage and proposing the most suitable cable landing site.

Acoustic and Environmental baseline survey, Alderney Commission for Renewable Energy, Alderney, 2010. Survey area encompassed a sand bank in close proximity to a proposed tidal turbine site. Side scan sonar, multi beam bathymetry, DDV and sediment sampler all utilised to produce a comprehensive dataset. Responsibilities included interpreting acoustic data with the aid of camera footage as ground truthing.

Marine Mammal Observation (MMO), Statoil, Sheerness, 2010. Lead supervisory role for MMO and supervision of Passive Acoustic Monitoring (PAM) system during the installation of the Sheringham Shoal wind farm. Responsibilities included ensuring watches were carried out at the right time and for the appropriate length of time before and during piling operations. All log keeping and paperwork. Communication with client representative onboard the piling vessel to ensure all parties were aware of piling operations and permission to pile.

Assessment of cold water coral reefs, Fugro Norske, North Sea (Norway), 2010. Lead environmental scientist during a site survey aimed at assessing quality and quantity of cold water coral reefs in an area of the northern North Sea. Sites were selected from low resolution side scan data. A Panther ROV was used to record the health and extent of reefs. Production of report at end of survey detailing location and health of reefs.

Oil rig site survey, Fugro, North Sea, 2010. Lead environmental scientist on a site and pipeline route survey in the North Sea. Responsibilities included side scan data analysis, selecting sites to ground truth using a high definition shallow water camera system and Day grab. Production of daily field report outlining findings.

Baseline habitat assessment, Gardline Environmental, North Sea, 2009. Lead environmental scientist on potential oil rig and pipeline surveys. Responsibilities included selecting sites to ground truth using DDV and sediment sampler from acoustic data sets. Production of daily field reports.

Habitat mapping, SSE Renewables, Sound of Islay, 2008- 2009. On board environmental scientist during habitat mapping and ground truthing survey using DDV. Responsibilities included assessing the suitability of several sites for the deployment of ADCPs and ultimately tidal turbines.

Position Title and No.	ENVIRONMENTAL OFFICER, K-4
Name:	Hemwantie Singh, Marine Water Quality Specialist
Date of Birth:	26/10/1983
Country of Citizenship/Residence	Guyana

Education:

Institution	Degree/Diploma/Certificate	Year
University of Guyana	MSc. Natural Resource Management	2016
University of Guyana	Post Graduate Diploma in Environmental Management	2012
University of Guyana	*Bachelor Degree (BSc)*, Environmental Science	2004

Employment Record:

Period	Name of employer, position / position. Contact info for references	Country	Summary of activities carried out, related to this Assignment
June 2011 to Present	Employer: CEMCO Inc *Position: Senior Environmental Environmentalist* For Reference Tel: 592-226-2773/ rlatchmansingh@cemcoguyana.com; Mr. R. Latchmansigh, Managing Director	Guyana	• Environmental Impact Assessments • Preparation of Project Environmental and Social Impact Assessment and Environmental and Social Management Plan. • Review of ESIA and ESMP • Preparation of Environmental risk assessments and risk management plans. • Preparation of traffic and water management plans. • Conducted stakeholder consultation sessions. • Assisted with Preparation of Stakeholders Engagement Plan and Review Process. • Community Liaison. • Environmental Quality testing including water and air quality. • Environmental quality monitoring.
August 2010 to March 2012	Employer: H.Nauth and Sons Civil Engineering Contractors *Position Environmental Manager* For Reference Tel 592 6232701 hnauthandsons@hotmail.com Mr. Kiran Nauth, Manager	Guyana	• Preparation of Site Environmental Management Plan • Preparation of Traffic Management Plan • Preparation of Health and Safety Plan • Preparation of Emergency Response Plan. • Environmental quality and compliance monitoring.
September 2008 to March 2012	Employer: Environmental Management Consultants *Position: Projects Environmental Officer* For Reference: Tel: 222-4565 emc@networksgy.com	Guyana	Worked on. • Environmental Impact Assessments and Management Plans. • Sea-Defence Legality Study. • Monitoring of numerous roadway construction projects

	Mr. Shyam Nokta, Managing Director		
May 2008 to October 2010	Employer: Falcon Construction and Transportation Services *Position : Environmental manager* *For Reference:* Meerza65@hotmail.com Mr. Azad Meerza, Managing Director	Guyana	• Routine inspection of construction activities and staging area for compliance with EMP. • Health and Safety Inspection • Weekly Inspection reports • Provision of Mitigation measures for non-compliances and other environmental problems. • Liaison with MOA, EPA and other agencies involved in the project • Community liaison in the project area. • Conduct Baseline Surveys

Adequacy for the assignment:

Detailed tasks assigned on consultant's team of experts:	Reference to Prior Work/ Assignments that Best Illustrates Capability to Handle the Assigned tasks
• Develop ESMP • Ensure the Environmental Social Assessment Framework (ESAF) and health and safety regulations are compiled with. • Supervise and provide guidance to the Health and Safety Officers on site. • Monitor the Contractor's HSE performance against requirements.	**Assignment No. 1** **Name of assignment or project: FLOOD RISK MANAGEMENT PROJECT (FRMP). PROJECT ID NO: P 147258. Lots 1, 2 and 3, Construction of Pump stations at Lusignan, Buxton and Enmore.** **Year**: July 2016 to March 2018: **Location**: Region 4, Guyana **Client:** Ministry of Agriculture (ASDU). **Positions held:** Senior Environmentalist. ***Duties*** • Environmental Impact Evaluation • Preparation of Project Environmental and Social Impact Assessment and Environmental and Social Management Plan. • Attend and conducted stakeholder consultation sessions. • Compliance Monitoring • Preparation of Non-Compliance and Inspection reports. **Assignment No. 2** **Name of assignment or project: Sheriff street- Mandela Avenue Roadway Design.** **Year**: July 2012 **Location**: Region 4, Guyana **Client:** Ministry of Public Works and Communication. **Positions held:** Senior Environmentalist. ***Duties*** • Environmental Impact Evaluation • Preparation of Project Environmental and Social Impact Assessment and Environmental and Social Management Plan.

- Attend and conducted stakeholder consultation sessions.
- Assisted with Preparation of Stakeholders Engagement Plan and Review Process.

Assignment No. 3
Name of assignment or project: Grove-Timehri Roadway Rehabilitation Project.
Year: July 2014
Location: Region 4, Guyana
Client: Ministry of Public Works and Communications
Positions held: Senior Environmentalist

Duties

- Environmental Impact Evaluation
- Preparation of Project Environmental and Social Impact Assessment and Environmental and Social Management Plan.
- Attend and conducted stakeholder consultation sessions.
- Assisted with Preparation of Stakeholders Engagement Plan and Review Process.

Assignment No. 4
Name of assignment or project: East Bank Berbice Roadway Design.
Year: July 2014
Location: Region 6, Guyana
Client: Ministry of Public Works and Communications
Positions held: Senior Environmentalist

Duties

- Environmental Impact Evaluation
- Preparation of Project Environmental and Social Impact Assessment and Environmental and Social Management Plan.
- Attend and conducted stakeholder consultation sessions.
- Assisted with Preparation of Stakeholders Engagement Plan and Review Process.

Assignment No. 5
Name of assignment or project: Canals Polder Roadway Design Project.
Year: July 2014
Location: Region 3, Guyana
Client: Ministry of Public Works and Communications
Positions held: Senior Environmentalist

Duties

- Environmental Impact Evaluation
- Preparation of Project Environmental and Social Impact Assessment and Environmental and Social Management Plan.
- Attend and conducted stakeholder consultation sessions.
- Assisted with Preparation of Stakeholders Engagement Plan and Review Process.

Assignment No. 6
Name of assignment or project: Ministry of Public Works and Communication, **CJIA- Expansion Project.**
Year: July 2012 to present
Location: Region 4, Guyana

Client: Ministry of Agriculture, National Drainage and Irrigation Authority
Positions held: Senior Environmentalist

Duties

- Environmental Impact Evaluation
- Preparation of Project Environmental and Social Impact Assessment and Environmental and Social Management Plan.
- Attend and conducted stakeholder consultation sessions.
- Assisted with Preparation of Stakeholders Engagement Plan and Review Process.

Assignment No. 7
Name of assignment or project: University of Guyana Science and Technology Support Project.
Year: July 2012 to present
Location: Region 4, Guyana
Client: Ministry of Education- World Bank
Positions held: Senior Environmentalist

- Review of Project ESA and ESMP.
- Preparation of Risk Assessment and Risk Management and health& Safety Plan
- Preparation of Environmental Management Plan.

Assignment No. 8
Name of assignment or project: Ministry of Public Works and Communication Bridges Rehabilitation Project, Phase II, Rehabilitation of Lot II Structures Lots B1 and B2.
Year: May 2010 to Present
Location: Regions 4 and 5, Guyana
Client: Ministry of Public Works and Communications**.**
Main project features: Rehabilitation of Roadway Structures (Timheri to Rosignol, Berbice), Rehabilitation of culverts, construction of 21 new pre-cast culverts and pre-stressed bridges as well as associated traffic and water diversions.
Positions held: Senior Environmentalist
Activities performed:

- Compliance Monitoring in accordance with ESIA and EMP.
- Addressed Non- Compliant activities.
- Supervised Implementation of Mitigation Measures
- Convened and Conducted Site meetings related to Environmental Management.

Assignment No. 9
Name of assignment or project: Conservancy Adaptation Project
Year: July 2012 to present
Location: Region 4, Guyana
Client: Ministry of Agriculture, National Drainage and Irrigation Authority

Main project features: The project aims to strengthen government and donor understanding of the East Demerara Water Conservancy (EDWC) system and coastal drainage patterns through the integration of advanced mapping and engineering analysis. The project also aims to carry out the design of infrastructure investments to improve drainage performance within the

Region 4 coastal lowlands, to improve the stability of the EDWC dam, to strengthen the institutional capacity for managing water and floodwater levels, and to guide interventions to reduce Guyana's vulnerability to floods.
Positions held: Senior Environmentalist
Activities performed: Data collection, review and preparation of necessary project documents (EIA and EMP) for Dam Feasibility aspect of project as well at Coastal Infrastructure works.

Assignment No. 10
Name of assignment or project: East Bank Demerara Public Road Four Lane Extension.
Year: November 2011- March 2012
Location: East Bank Demerara (Region 4), Guyana
Client: Ministry of Public Works and Communications
Main project features: Upgrading 5.4km of the main road and improvement of associated infrastructure to accommodate four lanes of traffic (upgrading from existing two lane).

- Widening and rehabilitation of existing carriageway
- Construction of additional two lanes
- Construction and expansion of bridges and culverts along road alignment
- Relocation of public utilities

Positions held: Environmental Inspector
Activities performed: Routine inspection of construction activities and staging area for compliance with EMP; Health and Safety Inspection; Weekly Inspection reports; Provision of Mitigation measures for non-compliances and other environmental problems; Liaison with MPW&C, EPA and other agencies involved in the project; Community liaison in the project area; Conduct Baseline Surveys

Assignment No. 11
Name of assignment or project: East Demerara Water Conservancy Northern Relief Channel and Associated Drainage and Irrigation Canals at Hope Doch Four
Year: June 2011- March 2012
Location: Guyana
Client: Ministry of Agriculture, National Drainage and Irrigation Authority
Main project features:
Excavation of a 10.3km long channel x 30m wide (bottom width) through clays as well as very weak organic soils (6.5km over clay, 2.3km over a mixture of clay and organic soils and 1.5km through organic soil – pegasse). This new channel with discharge capacity of 58 cubic metres per second will provide another relief to the East Demerara Water Conservancy; Construction of impervious embankments and berms
Positions held: Environmental Inspector
Activities performed:

- Compliance Monitoring in accordance with ESIA and EMP.
- Address Non- Compliant activities.
- Supervise Implementation of Mitigation Measures
- Convene and Conduct Site meetings related to Environmental Management.

Assignment No. 12
Name of assignment or project: Road Improvement and Rehabilitation Project: Rehabilitation of East and West Canje Road
Year: August 2010
Location: Berbice (Region 6), Guyana
Client: Ministry of Public Works and Communications, Works Services Group
Main project features: Roadway reconstruction, construction of pre-cast culverts and pre-stressed bridges
Positions held: Environmental Monitor
Activities performed:
Routine inspection of construction activities and staging area for compliance with EMP; Health and Safety Inspection; Weekly Inspection reports; Provision of Mitigation measures for non-compliances and other environmental problems; Liaison with MPW&C, EPA and other agencies involved in the project; Community liaison in the project area.; Conduct Baseline Survey.

Assignment No. 13
Name of assignment or project: Black Bush Polder Road Rehabilitation Project.
Year: May 2010 - May 2012
Location: Berbice (Region 6), Guyana
Client: Ministry of Public Works and Communications, Works Services Group
Main project features: Rehabilitation and reconstruction of approximately 35 km of flexible pavement with an AC finish and rehabilitation of timber and concrete bridges.
Positions held: Environmental Inspector
Activities performed:

- Compliance Monitoring in accordance with ESIA and EMP.
- Address Non- Compliant activities.
- Supervise Implementation of Mitigation Measures
- Convene and Conduct Site meetings related to Environmental Management.

Assignment No. 14
Name of assignment or project: Agricultural Export Diversification Programme: Canals Polder Control Structures and Access Roads.
Year: 2008
Location: Region 3, Guyana
Client: Ministry of Agriculture, National Drainage and Irrigation Authority
Main project features: Upgrade of access roads to fair weather status (≈14.5kmm)**;** Rehabilitate timber access bridges and reinforced concrete culverts; Desilting and widening of canals (≈14.5kmm); Rehabilitation and construction of drainage and irrigation control structures
Positions held: Environmental Inspector
Activities performed: Routine inspection of construction activities and staging area for compliance with EMP; Health and Safety Inspection; Weekly Inspection reports; Provision of Mitigation measures for non-compliances and other environmental problems; Liaison with MPW&C, EPA and other agencies involved in the project; Community liaison in the project area.; Conduct Baseline Surveys

Assignment No. 15

	Name of assignment or project: Project: Ministry of Public Works and Communication Bridges Rehabilitation Project, Phase 11, Rehabilitation of Lot 11 Structures Lot A1, A2 and 2B **Year:** August and Sept 2009 **Location:** Regions 4 and 5**,** Guyana **Client:** Ministry of Public Works and Communications **Main project features:** Rehabilitation of Roadway Structures (Timehri to Georgetown, installation of ore-cast box culverts and bridges), Rehabilitation of culverts, construction of new culverts and bridges, permanent revetment; permanent relocation of utilities and associated temporary traffic and water diversions. **Positions held:** Environmental Inspector **Activities performed:** Routine inspection of construction activities and staging area for compliance with EMP; Health and Safety Inspection; Weekly Inspection reports; Provision of Mitigation measures for non-compliances and other environmental problems; Liaison with MPW&C, EPA and other agencies involved in the project; Community liaison in the project area.; Conduct Baseline Surveys **Assignment No. 16** **Name of assignment or project:** Shawnee Service Station Soesdyke Linden Highway Junction (EMC) **Year:** 2008-2009 **Location:** Region 4, Guyana **Client:** Private Sector **Main project features:** Construction of gas station and other ancillary facilities including a food court and convenience store. **Positions held:** Environmental Inspector

FORM TECH-6 CURRICULUM VITAE (CV) FOR PROPOSED PROFESSIONAL STAFF

Position Title and No.	**Environmental, Health and Safety**
Name of Expert:	Michael Lowe
Date of Birth:	August 1st, 1997
Country of Citizenship/ Residence	Guyana

Education:

INSTITUTION	**Diploma / Certificate**	**YEAR**
Coursera	Global Environmental Management	2021
New Guyana School	Basics of Occupational Health and Safety	2019
University of Guyana	Bachelors of Science Degree in Environmental Studies	2018
St. Roses High School	Caribbean Examination Council – 9 Subjects	2014

6. **Membership of Professional Associations**:

7. **Other Training**:

8. **Countries of Work Experience**: Guyana

9. **Languages:**

Language	**Reading**	**Speaking**	**Writing**
English	Excellent	Excellent	Excellent

10. **Employment Record:**

PERIOD	**EMPLOYER**	**POSITIONS HELD**
July 2018 - Present	CEMCO Inc.	Environmental Officer

11. Detailed Tasks Assigned	**12. Work Undertaken that Best Illustrates Capacity to Handle the Tasks Assigned**
Task 4.4 – Manage Implementation of EMP	**Assignment No. 1**
	Name of assignment or project: Cunha Canal Rehabilitation Project **Year:** 2018 – 2019 **Location:** Land of Canaan, East Bank Demerara **Client:** Agriculture Sector Development Unit- Ministry of Agriculture **Main project features:** The objective of the Cunha Canal Rehabilitation Project for Guyana is to increase the capacity of the Cunha Canal to drain the East Demerara Water Conservancy and local agricultural areas in the recipient's territory. The flood of 2005 highlighted the significance of the risks posed by the weakened containment and drainage capacities of the

11. Detailed Tasks Assigned	12. Work Undertaken that Best Illustrates Capacity to Handle the Tasks Assigned
	EDWC and coastal drainage system. The project entails construction of two Sluices and a Bridge over the existing roadway to facilitate re-alignment of the canal. **Positions held:** Environmental Officer **Activities performed:** - Routine inspection of construction activities and staging area for compliance with Environmental Management Plan - Tri weakly Health and Safety Inspection - Weekly Inspection reports - Provision of Mitigation measures for non-compliances and other environmental problems - Liaison with MOA, EPA and other agencies involved in the project - Community liaison in the project area.
	Assignment No. 2
	Name of assignment or project: Cheddi Jagan International Airport Expansion Project **Year**: 2018 - 2019 **Location**: Timehri, **Client:** Ministry of Public Infrastructure **Main project features**: The Cheddi Jagan International Airport Expansion Project entails construction of the New Arrivals Terminal Building (NATB); Existing Terminal Building (ETB); Remote Apron; North East (NE) Runway Extension; South West (SW) Runway Extension; Diesel Generator Room (DGR); and Fire Pump Station. **Positions held:** Environmental Officer **Activities performed:** • Routine inspection of construction activities and staging area for compliance with EMP. • Health and Safety Inspection • Weekly Inspection reports • Provision of Mitigation measures for non-compliances and other environmental problems. • Liaison with MPI, EPA and other agencies involved in the project • Community liaison in the project area.
	Assignment No. 3
	Name of assignment or project: Community Based Livelihood Enhancement Fisheries Development Project - Lot 1 **Year:** 2019 – 2020 **Location:** Victoria, East Coast Demerara **Client:** Basic Needs Trust Fund - Ministry of Finance **Main project features:** Development of a 1600 Kg to a maximum of 3700 Kg per day Processing Facility that would cater for artisanal fishing operators and trawler owners.

11. Detailed Tasks Assigned	12. Work Undertaken that Best Illustrates Capacity to Handle the Tasks Assigned
	Positions held: Environmental Officer **Activities performed:** - Preparation of the Environmental and Social Management Plan. - Attend team meetings - Provision of Mitigation measures for environmental problems during design phase.
	Assignment No. 4
	Name of assignment or project: Construction of Processing and Packaging Facility – Lot 2 **Year:** 2019 – 2020 **Location:** NAREI, Mon Repos, East Coast Demerara **Client:** Basic Needs Trust Fund - Ministry of Finance **Main project features:** Project entail the construction of a modern agro-processing and packaging facility to support value added production in the agricultural sector. **Positions held**: Environmental Officer **Activities performed:** - Preparation of the Environmental and Social Management Plan. - Attend team meetings - Provision of Mitigation measures for environmental problems during design phase. - Routine inspection of construction activities and staging area for compliance with EMP. - Health and Safety Inspection. - Weekly Inspection reports.
	Assignment No. 5
	Name of assignment or project: Water and Sanitation Systems Enhancement Projects **Year:** 2019 – 2020 **Location(s):** Wowetta, Rupertee, Aranaputa, Kwaimatta, Fly Hill, and Shulinab; Region 9 **Client:** Basic Needs Trust Fund - Ministry of Finance **Main project features:** Water supply to the isolated deemed villages in Region 9 was insufficient and unsafe in some cases. Residents obtained water from hand dug wells, approximately 15-30 minutes (or more in some cases) to the water source. With the recognition of the challenge for clean and safe water, installation of a distribution network with stand pipes at strategic locations, became a necessity for development of the villages. **Positions held:** Environmental Officer

11. Detailed Tasks Assigned	12. Work Undertaken that Best Illustrates Capacity to Handle the Tasks Assigned
	Activities performed: - Routine inspection of construction activities and staging area for compliance with Environmental Management Plan. - Weekly Health and Safety Inspection. - Monthly inspection reports. - Preparation for the Environmental Management Plan. - Attend team meetings.

Certification:

I, the undersigned, certify that to the best of my knowledge and belief, this CV correctly describes myself, my qualifications, and my experience, and I am available to undertake the assignment in case of an award. I understand that any misstatement or misrepresentation described herein may lead to my disqualification or dismissal by the Client, and/or sanctions by the Bank.

Name of authorized Representative of the Consultant | Signature | Date: 22/03/2021

Shwet Prakash

Partner
Hydrodynamic Modeling Specialist

Shwet is a Partner who manages ERM's Water Resources, Climate Change and Modeling Group. He is an oceanographer and has been managing and delivering water resources and modeling services. Shwet has been involved in developing state of the art chemical fate and transport models for a variety of offshore, coastal and inland water quality applications. His experience includes directing projects that include hydrodynamic studies, groundwater contamination, fate and transport, accidental oil spill studies, sediment transport and scour studies, regulatory permitting climate change risk analysis and adaptation. Shwet has provided these services to most of the major oil & gas companies

Experience: 14 years' experience in oil & gas, power, chemical, mining and manufacturing industry.

Email: Shwet.Prakash@erm.com

Education

- M.S. (Civil Engineering), University at Buffalo, State University of New York, NY, February 2004
- B.S. (Civil Engineering), Indian Institute of Technology, Bombay, India, May 2001
- Professional Development courses in Environmental Hydrodynamics and Sediment Transport Modeling with POM and ECOMSED, Stevens Institute of Technology, Hoboken, NJ

Languages

- English, native speaker

Fields of Competence

- Computational fluid dynamics
- 1-D, 2-D and 3-D numerical modeling of coastal and shelf processes including hydrodynamics and waves
- Chemical transport and fate and water quality modeling
- Ecological risk assessment & spill modeling
- Sediment transport modeling
- Particle tracking and entrainment modeling
- Groundwater modeling
- Programming in FORTRAN, C, Visual Basic and HTML
- Field data processing and analysis
- Marina design and water quality
- Coastal zone protection

Key Industry Sectors

- Oil and Gas
- Electric Utility (fossil fuel, nuclear, wind and hydropower)
- Mining

Key Projects

Water Quality Impact Assessment from offshore FPSO, Guyana
Managed a comprehensive modeling exercise to quantify environmental impacts related to the commissioning of an FPSO offshore Guyana. Environmental risks associated to wastewater discharge, dredging, drill cuttings, mud discharge, pipeline hydrotesting and accidental spills were estimated using numerical models. Individual wastewater components were modeled and evaluated against relevant ambient water quality standards. Assessments were performed based on detailed metocean study of the region to identify critical circulatory patterns. Conducted workshops for local Guyanese government agencies including Guyana EPA.

Multiple Specialist Studies related to offshore O&G development in Gulf of Mexico
Managing and developing various large scale comprehensive water quality and thermal impacts studies in Gulf of Mexico. Modeling studies typically included oceanography and metocean assessments, assessment of chlorine discharges, thermal discharges, wastewater discharges, brine water discharges and accidental spills into the open waters of the Gulf.

Brine Discharge Study for Onshore LNG Facilities, Ras Laffan Industrial City, Qatar
Directed a comprehensive study to assess the impacts of brine discharge from various operators in Ras Laffan Industrial City (RLIC). Assessment included performing a complete three-dimensional hydrodynamic and water quality model for the waters offshore RLIC. Multiple scenarios were developed including normal and upset cases along with a combination of various ambient conditions such as Shamal winds, typical and extreme water temperatures, and multiple tidal cycles. Three different locations of potential discharge of brine release were evaluated to identify the location that would result in least environmental impact. Study results were presented to Qatar's MME.

Multiple Studies Related to Water Quality and Thermal Impacts from Onshore LNG facilities, Qatar
Managing and developing various large scale comprehensive water quality and thermal impacts studies in Ras Laffan Industrial City, Qatar. Modeling studies included assessment of chlorine discharges, thermal discharges and brine water discharges into the Arabian Gulf.

Multiple Specialist Studies related to FLNG development offshore Mozambique
Managed five specialist studies related to the environmental impacts from operational and accidental discharges from an FLNG. Study included development of a comprehensive flow, transport and fate model for thermal, produced water and wastewater discharge along with consideration of accidental oil spill and planned drilling operations.

Development of Constructed Wetlands Model for Water Reuse, Qatar
Directed development of numerical model for constructed wetlands that could aid in designing these wetlands for treatment of wastewater through the removal of nutrients, metals and organic compounds. A functioning wetlands system would allow for the reuse of treated process water for irrigation or recharging groundwater.

Water Quality Impact Assessment from Onshore LNG Terminal Expansion, Indonesia
Managed a comprehensive modeling exercise to quantify environmental impacts related to expansion of an onshore LNG facility in Indonesia. Environmental risks associated to wastewater discharge, dredging, drill cuttings and mud discharge and pipeline hydrotesting were estimated using a 3-D hydrodynamic and transport model. Individual wastewater components were modeled and evaluated against relevant ambient water quality standards.

Lower Passaic River Superfund Site Hydrodynamic and Contaminated Sediment Transport Modeling
This confidential study included analysis of current meter and water surface elevation data and modeling of the hydrodynamics and transport of sediments. The purpose of the study was to support our client, a PRP, in the interim allocation process and to help establish the magnitude of dispersal of material introduced into the prominent Newark Bay river-estuary system. This effort also included review of EPA- and Cooperating Parties Group-generated documents and datasets (particularly EPA's Framework Document and modeling reports), submission of comments, and attendance at Technical Committee meetings.

Dredging Impact Assessment, Saigon Premier Container Terminal, Vietnam
The purpose of this project was to estimate the potential impacts of proposed dredging operations for the Saigon Premier Container Terminal. Three types of impacts were examined: re-suspended sediments entering the water column; suspended and newly exposed bottom sediments exerting a demand on the water column's dissolved oxygen (DO); and, changes in currents caused by the new bottom configuration. Model results predicted magnitudes, durations, and locations of the suspended solids and dissolved oxygen reductions compared to criteria.

Deposition and erosion studies in Tawau Harbor, Vietnam
The hydrodynamic and sediment transport modules of GEMSS were used to evaluate the deposition and erosion characteristics of bottom sediments in Tawau Harbor, Vietnam. The hydrodynamic circulation in the harbor was obtained using tides and winds. Sediment bed characteristics were assumed as non-cohesive and deposition and erosion probabilities were estimated for each model grid cell in the harbor by comparing the bottom currents with the threshold velocities for the movement of sediment particles of different sizes.

Submarine Tailings Disposal Studies in Stephens Passage, Juneau, Alaska
The purpose of this study was to evaluate the impact of proposed submarine tailings outfall in Stephens Passage. The only practical way to include the effects of the complex bathymetry and ocean currents on tailings distribution on the ocean bottom was to use a numerical model to simulate the relevant processes. The models were used to evaluate the distribution of tailings on the ocean bottom based on design parameters for the tailings pipe, and on the model predicted ocean currents. The model results were used to set up sediment monitoring program in the Passage.

Oil Spill Response Planning and Impact Assessment for various clients and fields, offshore Malaysia
Currently developing models to estimate the environmental impacts from accidental spills during the operations of MOPUs and FSOs offshore Malaysia. Responsibilities include overall project management of these modeling projects, client liaison and regulatory support.

Oil Spill Impact Assessment for confidential field development, offshore Western Australia
Currently developing models to estimate the environmental impacts from accidental spills during the operations of FLNGs (Sunrise, Prelude and Scarborough), MOPUs and FSOs offshore Australia. Responsibilities include overall project management of these modeling projects that include three individual clusters.

Oil Spill Response Planning and Impact Assessment for various clients and fields, offshore Africa
Currently directing several model developments to estimate the environmental impacts from accidental and operational discharges including spills during the operations of offshore production units offshore Africa. Responsibilities include overall project management of these modeling projects, client liaison and regulatory support.

Oil Spill Modeling, MA
Involved in development of an oil spill fate model. The model was developed using GEMSS-COSIM (Chemical and Oil Spill Impact Module). The study required analysis of oil spill fate and its shoreline interaction under varying meteorological and hydrodynamic conditions.

Entrainment Modeling Regassification Facility, New Jersey
Proposed development of an LNG import terminal on the Delaware River in Gloucester County, NJ. During vessel unloading while at berth, LNG carriers take on about 30,000 m3 of water to maintain hydraulic stability when empty. Concerns exist regarding the entrainment effects and possible fishery losses due to this ballast water intake. Striped Bass, White Perch and Bay Anchovy are the species of concern since they consistently dominate the ichthyoplankton population in the Delaware River. ERM simulated intake effects using a high resolution hydrodynamic model to estimate entrainment rates for various life stages of these species of concern. These rates were used to estimate the loss of equivalent adults using a specialized module developed by ERM.

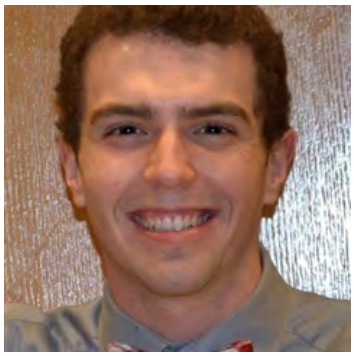
Jacob Guise

Hydrodynamic Modeling Specialist

Jacob has over 2 years of experience in environmental consulting, focusing on environmental impact assessments, remediation, risk assessment, water quality/resources modeling, thermal, and chemical discharge modeling. With a background in environmental engineering, his primary focus is on the Power, and Oil and Gas sector. He has prepared environmental impact assessments for projects located around the coast of Africa (Cote d'Ivore, Sao Tome and Principe, and Equatorial Guinea), Southeast Asia, Montenegro, and in the Gulf of Mexico. Jacob has worked with Exxon Mobil for about a year, and has been part of ERM's support to EEPGL in Guyana since 2019.



Experience: 2 years of experience in Water Resources and Water Quality Modeling

Email: Jacob.Guise@erm.com

Education

- Bachelors of Environmental Engineering, Biological and Chemical Processes, University of Delaware, USA, 2018

Languages

- English, native speaker

Fields of Competence

- CORMIX thermal plume modelling
- COSIM-Oil Spill Modelling
- Chemistry
- Geographic Information System (GIS)
- Python/Visual Basic
- Water resources

Key Industry Sectors

- Oil and Gas
- Power

Key Projects

Water Quality Analysis off the Coast of Brunei
This project focused on the impacts of an oil and gas company's produce water discharge off the coast of Brunei. A three-dimensional, hydrodynamic model was built in order to capture the near field area, and the effects of a neighboring estuary. Jacob supported this work in preparing input files and processing output files from the Generalized Environmental Model for Surface water Systems (GEMSS). Constituent concentrations were compared to Brunei water quality standards.

Discharge Modeling for EEPGL off the Coast of Guyana
Assessed compliance of thermal and chemical discharged due to changes in water quality standards relative to the mixing zone. CORMIX Modelling was ran with local water body conditions and discharge characteristics to determine concentration and percent reduction at multiple distances from the discharges.

Oil Spill and Drill Cuttings Deposition Modeling
Performed oil spill and drill cuttings deposition modeling for Environmental Impact Assessments (EIA) for over 20 projects around the world including around the coast of Africa (including, Cote d'Ivore, Sao Tome and Principe, and Equatorial Guinea), Southeast Asia (including Brunei), Montenegro, and in the Gulf of Mexico. Supported these projects through creation of control files, executing model runs, producing figures, analyzing results, and writing reports.

Wastewater Discharge Temperature Modeling of in United States
Assessed compliance of a thermal discharge due to changes in water quality standards relative to the mixing zone using data analysis and CORMIX Modelling was based on local water body conditions and discharge characteristics.

Hydraulic Zone of Influence Calculations in Southern United States
Assessed compliance of hydraulic intake zones as it relates to meeting the requirements of the United States' Clean Water Act (CWA) 316(b) rule issued on October 14, 2014. The zone of influence shape are based on the dimensions, design intake flow, and surrounding lake/river velocity.

Mark E. Garrison

Air Quality Modeling Specialist

Mark works out of the ERM Philadelphia office in Malvern. He has several years of experience providing expert consultation related to litigation, including expert testimony. His extensive experience in the application of air quality models to assess releases of criteria and toxic air pollutants. Mark has detailed knowledge of the technical, regulatory, and policy issues related to dispersion modeling of new and existing sources and modeling the effects of accidental releases of toxic chemicals; special expertise in modeling sources in complex terrain and in the application of advanced models. He has extensive experience in modeling for PSD and NA-NSR permitting, with special emphasis on electric utility power plants. Mark is author of numerous papers presented at technical conferences on a wide variety of modeling topics.

Experience: 40 years' experience as a meteorologist and air quality dispersion modeler in the environmental consulting field.

Key Projects

Modeling
Currently directing and conducting modeling for sulfur recovery units (SRUs) at ten facilities in Saudi Arabia. Modeling is being conducted with CALPUFF and meteorological data developed using WRF and MMIF at grid resolutions down to 1.3 km.

Modeling
Directed and conducted modeling in support of an EIA for a 2.4GW Integrated Gasification/Combined Cycle (IGCC) project north of Jazan, Saudi Arabia. Both CALPUFF and AERMOD were used to model emissions from the facility and an adjacent refinery. Meteorological data prepared by CALMET was based on WRF prognostic model wind fields.

Modeling for Gas Facility
Directed and conducted modeling in support of an expansion at a gas processing facility in Saudi Arabia. AERMOD and CALPUFF were both used in this study, and several approaches to developing meteorological inputs were tested, including: single point measurements, gridded meteorological data from MM5, single point and full profile winds extracted from MM5 output data sets. An in-depth analysis was conducted that examined the underlying scientific basis for differences in predictions between different models and different meteorological approaches.

Modeling for a Refinery
Directed and conducted modeling in support of an EIA for a major expansion project at a refinery in Saudi Arabia. CALPUFF was used for this project, with meteorological data prepared by CALMET based on MM5 prognostic model wind fields.

Modeling for a Gas Facility
Completed a modeling analysis of ambient impacts due to emissions from a Greenfield gas processing facility in Saudi Arabia. CALPUFF was used for this project, with meteorological data prepared by CALMET based on MM5 prognostic model wind fields. Numerous scenarios were modeled to determine the optimum plant configuration; modeling of releases from high pressure and acid gas flares was conducted to determine impacts.

Modeling for Mining
Directed and conducted modeling using CALPUFF with WRF meteorological inputs for two mining projects in Canada. Analyses included modeling of hundreds of individual sources at up to 40,000 receptors, to assess compliance with ambient air quality standards, deposition impacts to local vegetation and wildlife, and acid deposition impacts.

Modeling
Conducts modeling as the lead air quality modeling specialist for the Maryland Department of Natural Resources Power Plant Research Program (PPRP) review of several new power plant applications, including the use of AERMOD with special emphasis on addressing the 1-hour NAAQS for SO2 and NO2. Recent work includes use of the SCICHEM model to address secondary impacts on ozone and PM2.5 due to emissions from single sources.

Legal/Expert Witness
Serves as an expert witness in Maryland Public Service Commission cases involving new power plant air quality impacts.

Modeling for Oil Project
Directed and conducted modeling using CALPUFF with WRF meteorological inputs for an oil exploration and production project in the Atlantic Ocean off the coast of Georgetown, Guyana in South America. Modeling included consideration of offshore sources and emissions from delivery ships from shore to the project area.

Modeling
Directed a study that focused on the use of developing meteorological inputs to AERMOD based on WRF model outputs processed with MMIF and AERMET, evaluating the performance of WRF compared to measured wind profiles, and evaluating the performance of AERMOD compared to measured concentrations.

The study is using the Martins Creek data set, consisting of a full year of wind profile measurements and hourly SO2 concentrations at eight monitors in complex terrain. Results of the study were presented at an AWMA Specialty Conference (April 2016).

Modeling for Power Plant
Directed and conducted modeling of SO2 emissions from four coal-fired power plants for confidential clients in Texas to address compliance with the new 1-hour NAAQS for SO2. Modeling included exploration of numerous options for creating and using different meteorological data, the use of CEMs data to estimate the effects of actual emissions variability, and options involving the identification and processing of measured background concentrations.

Modeling and Permitting
Directing an on-going project for a confidential client, in support of PSD permitting of a new generating station in complex terrain. The project is focused on developing meteorological inputs to AERMOD based on WRF model outputs processed with MMIF and AERMET. The modeling with WRF includes innovative approaches to developing refined land use and terrain grids which are key to simulating winds in complex terrain. A protocol was developed for review by EPA OAQPS, intended to gain approval of this approach consistent with EPA's proposed revisions to the Guideline on Air Quality Models.

Modeling
Directing an on-going project for the Maryland Department of Natural Resources Power Plant Research Program (PPRP) that involves development and evaluation of WRF data sets across the State, for possible use in local scale modeling using the WRF data processed by MMIF and AERMET.

Modeling for Gas Facility
Directed a PSD air quality modeling analysis for a new natural gas fired power generation facility in Northeast Pennsylvania. Meteorological data from a nearby tall tower were used in the analysis. An innovative technique using the Weather Research and Forecast (WRF) meteorological model was used, and approved, to demonstrate that the tall tower observations were representative of the project site in an area of complex terrain.

Modeling for Glass Manufacturing Facility
Conducted modeling and prepared a justification document for the use of the ARM2 NOx to NO2 conversion technique, for a glass manufacturing facility in New York State. The U.S. EPA Office of Air Quality Planning and Standards (OAQPS) issued a clearinghouse memorandum approving the justification; this was the first ARM2 approval in the U.S.

Modeling
Supervised and conducted modeling with CALPUFF to determine visibility impacts on Class I areas using MM5-based data for facilities in Alaska (Fertilizer plant), South Carolina (Steel Mill), Pennsylvania (Two Petroleum Refineries), Nebraska (Fertilizer Manufacturing), Oklahoma (Petroleum Refinery), and Texas (Three Carbon Black Facilities). Modeling was conducted in support of BART exemption for the regional haze rule and BART engineering analyses. These projects included the development of meteorological inputs to CALPUFF using CALMET with native format MM5, incorporating local observations, and extraction and evaluation of the effects on regional haze of modeled concentrations.

Modeling
Conducted modeling of two industrial facilities to address compliance with the new 1-hour NAAQS for NO2 and SO2, including in-depth source culpability analyses and in-depth analysis of the OLM and PVMRM Tier 3 approaches to addressing NO to NO2 conversion.

Modeling
Directed and conducted modeling of PM10 and PM2.5 emissions from a biomass power plant in Minnesota. Conducted detailed diagnostic modeling to determine source culpabilities.

Legal/Expert Report
Assisted in the preparation of an expert report in support of a power company defendant involving allegations by the government of avoidance of New Source Review (NSR) requirements for over a dozen mid-western and eastern coal-fired power plants.

Modeling
Directed and conducted modeling with AERMOD in support of an EIA for a proposed fluidized bed power plant firing coal and petroleum coke in Guatemala. Modeling included numerous existing sources, and incorporated measured concentrations as background. Represented client in meetings, conference calls, and correspondence with the IFC.

Modeling
Directed and conducted modeling with AERMOD in support of an EIA for a proposed gas-fired combustion turbine in Peru. Modeling included numerous existing sources. Meteorological inputs were developed from MM5 files, and the advanced PVMRM technique was used to evaluate conversion of NOx to NO2.

Legal/Expert Witness
Served as an expert witness and prepared an expert report in litigation involving the air quality impacts of a gasoline spill, successfully avoiding class certification.

Modeling
Directed and conducted modeling of PM10 emissions from a refinery in New Jersey as part of an update to a PSD application. Project successfully demonstrated compliance with the NAAQS for PM10 based on a region-wide, multi-source analysis.

Modeling
Conducted modeling with the Offshore Coastal Dispersion (OCD) model to evaluate the effects of drilling operations in Bock 15 off of the coast of Angola. Project included processing and evaluation of both land and overwater meteorological data.

Modeling
Directed and conducted modeling in support of a proposed new refinery for a confidential client. CALPUFF was used for this analysis for estimating near-field impacts, with meteorological inputs developed from WRF prognostic model output data files. Since complex terrain was involved, the advanced terrain treatment within CALPUFF was employed and direct comparisons were made between the CALPUFF predictions and predictions from the CTDMPLUS model.

Modeling for Aluminum Smelting
Conducted modeling using CALPUFF of proposed greenfield aluminum smelters in Algeria and Saudi Arabia. Analyses included utilizing specialized approaches for modeling buoyant line sources (potroom exhaust), and evaluations of hydrogen fluoride, SO2, NOx, PM10 and PM2.5, and PAH emissions to determine ambient impacts for comparison to relevant Algeria, Saudi Arabia, WHO, IFC, and EU standards. The Saudi Arabia project was evaluated as part of the King Abdullah Economic City (KAEC) development.

Modeling for Aluminum Smelting
Conducted modeling in support of an aluminum smelter modernization project in New York State. The BLP, AERMOD, and CALPUFF models were evaluated as part of this project. Pollutants modeled include SO2, NOx, and HF from stack and fugitive sources.

Modeling for Aluminum Smelting
Conducted modeling using CALPUFF of a proposed aluminum smelter expansion project in Brazil. Analyzed impacts of hydrogen fluoride, SO2, NOx, and PM10 emissions to compare modeled concentrations to ambient measurements as well as for comparison to relevant ambient standards.

Modeling
Conducted extensive modeling with AERMOD to evaluate the ambient impacts of potential repowering projects at two sites on Long Island, as part of a larger repowering feasibility study. Numerous optional scenarios were modeled and recommendations provided to address air quality requirements of PSD, NNSR, and the State and City Environmental Quality Review (SEQR and CEQR) processes.

Modeling for Aluminum Refinery
Utilized AERMOD to evaluate the impacts of a proposed expansion project at an aluminum refinery in Suriname. The pollutants which were evaluated included nitrogen oxides (NOx), sulfur dioxide (SO2), carbon monoxide (CO), and particulate matter (PM). The results of the modeling analysis were compared to United States Environmental Protection Agency's (USEPA) ambient air quality standards. In addition, the impacts of emissions of hazardous air pollutants (HAPs) from the project on health risks were evaluated.

Modeling
Conducted modeling of the atmospheric transport, transformation and fate of mercury emitted by coal-fired power plants and other source types for the Maryland Department of Natural Resources Power Plant Research Program (PPRP). Developed a speciated mercury emissions inventories for the Eastern U.S., and developed a simplified mercury transformation scheme that has been incorporated into CALPUFF. Model evaluations were performed comparing model predictions to, and analysis of data collected at Mercury Deposition Network (MDN) sites.

Impact Analysis
Performed a cumulative impact analysis for several new electric generation facilities in Maryland utilizing CALMET and CALPUFF, including the effect of multiple plants on visibility resources in the Shenandoah National Park and an assessment of ambient standards in Maryland.

Scientific Peer Review
Participated in scientific peer review panels for the new AERMOD and CALPUFF models at the invitation of the U.S. EPA. Developed comments on the scientific and performance aspects of AERMOD and CALPUFF.

Analysis
Performed a full-scale analysis using the CALMET/CALPUFF modeling system to assess Nitrogen deposition to the Chesapeake Bay resulting from NOx emissions from sources located up to 1000 kilometers from the Bay. Conducted evaluations of the performance of CALPUFF and developed proposed improvements.

Modeling
Performed dispersion modeling in support of accidental release assessments for Clean Air Act 112(r) Risk Management Plan for chemical, paper and other industries at over a dozen facilities using the ALOHA, SLAB, and DEGADIS models.

Modeling
Conducted modeling for input to a risk assessment for a manufacturing facility in Albuquerque, New Mexico using CALPUFF for a local, complex wind application.

Air Quality
Prepared a comprehensive set of input files including MM4, upper air, surface, precipitation, buoy, ozone, land use, and terrain and ran CALMET for Public Service Electric and Gas in New Jersey. Provided evaluation of resultant wind fields.

Legal/Expert Reports
Prepared expert reports including dispersion modeling to address exposure to airborne asbestos particles in two court cases, both of which were settled with plaintiffs prior to trial.

Legal/Expert Report
Prepared an expert report in support of defendant involving the effects of airborne fluoride on the environment in the vicinity of an industrial facility in

Pennsylvania; was deposed by plaintiffs attorney in this case which was settled before going to trial.

Legal/Expert Oversight
Provided expert oversight in a project to estimate metals deposition to several watersheds in the L.A. Basin, due to emissions from seven petroleum refineries. Accomplishments include the development of meteorological input files using CALMET, based on MM5 data developed by the California Air Resources Board and available local observations.

Modeling
Directed and conducted modeling of criteria and toxic emissions, including mercury, from a proposed waste-to-energy facility in Baltimore, MD. Modeling was conducted on behalf of PPRP as part of the environmental review of the facility, and includes modeling of NOx and SO2 emissions to address the new 1-hour NAAQS for NO2 and SO2.

Air Quality Modeling
Conducted extensive air quality modeling to address SO2 ambient standards compliance issues for a refinery in Oklahoma. Work involved model evaluation comparing predicted to measured ambient concentrations. Models included AERMOD and ISCST3. Project included processing and evaluation of meteorological data for ISCST3 and AERMOD.

Olga Samani

Senior Scientist

Olga Samani is a Senior Scientist based in Boston, Massachusetts. She has extensive experience with air quality modeling, emissions inventory development, source characterization, and risk assessment. Olga has conducted a wide range of projects involving the application of dispersion models (e.g., AERMOD, CALPUFF, VISCREEN, PLUVIEW, OCD) for industrial clients ranging from simple stack applications to complex projects involving an array of stacks and fugitive emission sources in the US and many countries around the world. Performed daily "predictive modeling" to confirm that planned operations for the following day will not cause or contribute to a modeled NAAQS exceedance. Performed monthly "hindcast modeling" using actual station emissions parameters and actual hourly meteorological conditions for each day, for comparison to the NAAQS as well as actual monitored concentrations. She has also been involved a number of challenging modeling applications designed to demonstrate compliance with the newly promulgated NO_2, SO_2, and $PM_{2.5}$ ambient standards ranging from small indusial boilers to combined cycle, coal fired power plants, steel and paper mills in support of NAAQS, PSD, BART project, SIP attainment demonstrations, and Hazardous Air Pollutants heath and ecological risk assessments.

Experience: 18+ years of experience in consulting and air quality analysis services in the oil & gas, power industry, chemical, and manufacturing sectors

Key Projects

Environmental Impact Assessment

Environmental Impact Statement for a Proposed Prince Rupert LNG Terminal, British Columbia, Canada
Led the effort of the air dispersion modeling team to develop the Environmental Impact Statement for an LNG terminal. Worked closely with the BC Ministry of Environment to address concerns related to the modeling procedures and meteorological data development. Developed high-resolution meteorological data and conducted CALPUFF modeling of the sources associated with the proposed LNG facility construction and operation to demonstrate compliance with ambient standards.

Air Quality Assessment of the Vancouver Fraser Port Authority Centerm Expansion Project, Vancouver, British Columbia, Canada
Led the effort of the air dispersion modeling team to develop the Air Quality Assessment for the terminal expansion. Worked closely with the BC Ministry of Environment to address concerns related to the modeling procedures and meteorological data development. Developed high-resolution meteorological data and conducted CALPUFF modeling of the sources associated with the proposed terminal expansion to demonstrate compliance with ambient standards.

Environmental Impact Assessment for the Proposed Toco Marine Port, Trinidad
Conducted air dispersion modeling of the construction and operational phase. Performed CALPUFF modeling of marine vessels, onshore sources, and construction equipment to demonstrate compliance with the Trinidad and Tobago ambient air standards and International Finance Corporation guidelines.

1-Hour SO_2 Data Requirement Rule in Complex Terrain

1-Hour SO_2 Demonstration for Eastman Chemical Manufacturing Facility, Tennessee
Primary investigator for site-specific monitoring and modeling study to resolve an SO_2 non-attainment area in Kingsport, TN. The study has involved installation of meteorological and monitoring equipment, negotiation of monitoring and modeling protocols with reviewing agencies, and EPA approval of a site-specific dispersion model. Performed meteorological data sensitivity analysis utilizing the collected meteorological data and the Weather Research Forecast (WRF) prognostic meteorological data. Conducted numerous CALPUFF and AERMOD model runs to find a compliance scenario for several continuously operating industrial sources using actual emissions.

1-Hour SO_2 Demonstration for GenOn Facilities, Pennsylvania and Ohio
Primary investigator for modeling study to resolve 1-hour SO_2 non-attainment area near the Conemaugh and Seward Generating Stations. Conducted AERMOD modeling using actual emissions from the major coal-fired power plants (Keyston, Homer City, Seward, and Conemaugh) to demostrate complaince with the 1-hour SO_2. Innovative approach was implemented and approved to model complex terrain receptors with the onsite met data and simple terrain was modeled with the airport met data. Applied EPA procedure of randomly reassigned emissions to establish a longer-term averaging.

Litigation Support

Provided litigation modeling expertise for the expert witness report and declarations in support of defendants for Sierra Club vs. Ameren Misouri. Provided litigation modeling expertise for the expert witness report and declarations in support of defendants for Sierra Club vs. Energy Future Holdings Corporation and Luminant Generationg

Company LLC regarding self-reported opacity excursions at the Big Brown Steam Electric Station in Texas during the period 2007-2010.

PSD Permit Applications

PSD Permit Application for Nucor **Steel Mill, Illinois**
Lead the effort to prepare a PSD permit modification application for a large steel mill. The project triggered PSD Review for all pollutants. Performed NAAQS and PSD increment modeling for all pollutants. Performed screening and review of potential impacts at Class I areas in the region. Performed VISCREEN visibility modeling. Performed Tier-I screening for potential ozone and secondary PM2.5 impacts using the MERPs approach. Worked closely with the ADEQ to address all concerns related to the modeling approach and inventory.

PSD Permit Application for Alaska LNG
Liquefaction Facility, Nikitski, Alaska
Lead the effort to prepare a PSD permit application for an onshore LNG facility. Processed meteorological data and conducted CALPUFF modeling of the onshore stationary and marine sources to demonstrate compliance with the PSD increments, AQRVs (visibility and acidic deposition), and NAAQS at nearby Class I and sensitive Class II areas.

PSD Permit Application for Alaska LNG Gas Treatment Plant Permit Application, North Slope, Alaska
Lead the effort to prepare a PSD permit application for the onshore GTP facility. Processed meteorological data and conducted CALPUFF modeling of the stationary sources to show compliance with the PSD increments, AQRVs (visibility and acidic deposition), and NAAQS.

PSD Permit Application for ConocoPhillips **Chukchi Sea, Exploratory Drilling Project, Devil's Paw Prospect, Alaska**
Lead the effort to prepare a PSD permit application for the offshore drilling project. Processed meteorological data for CALPUFF and OCD models. Conducted modeling of the project-related and mobile emissions associated with the exploratory drilling activities to demonstrate compliance with the NAAQS.

PSD Permit Application for ConocoPhillips **Beacon Port LNG Terminal, Gulf of Mexico**
Lead the effort to prepare a PSD permit application for the LNG project. Processed meteorological data for CALPUFF, OCD, and OZIPR (ozone) models. Conducted modeling of the LNG terminal sources and the riser platform in the Gulf of Mexico to demonstate compliance with the PSD increments, AQRVs, and NAAQS.

Surya Ramaswamy

Air Quality Modeling Specialist

Surya is a Principal Consultant working out of ERM's Philadelphia office in Malvern, PA. He has experiences in air quality modeling including emulating, evaluating and processing the meteorological data from prognostic models. His meteorology experience includes implement, update and maintain an ensemble prognostic modeling system such as MM5, WRF, CAMx, and SMOKE on Linux clusters. In addition, he has also extensive experience in Shell, C, FORTRAN, python, R, and Visual Basic (VB) programming. His modeling experience also includes compiling regional scale emission inventory, and evaluating model performance with monitoring data. He has worked extensively in AERMOD, CALPUFF, SCICHEM, MMIF, MOVES, CAMx, SMOKE, and CMAQ. He also has experience in build, and configure Linux clusters to ensemble various models.

[Double click to add pic]

Experience: 14 years' experience of experience in meteorological data evaluation and processing.

Education

- Certificate in Weather Forecasting, Penn State, Graduating in Fall 2012
- M.S., Environmental Engineering, University of Tennessee, 2005
- B.E., Mechanical Engineering, University of Madras, India, 2001

Languages

- English, native speaker
- Tamil, Fluent
- Hindi, Fluent

Fields of Competence

- Air quality dispersion modeling (CALPUFF, AERMOD, ISC-PRIME, and ISCST3)
- Use of regional scale models including SMOKE, CAMx, and CMAQ
- Programming experience in C, FORTRAN, python, R, and VB
- Proficiency in Linux system administration and shell programming (C shell and Bash)
- Experience in scientific programming and familiarity with netCDF format and visualization tools including pynetCDF, SURFER, Panoply, CDO, NCAR Graphics, ncBrowse, and ncview
- Developing prognostic model data using WRF/MM5

Key Industry Sector

- Power
- Metals/Mining
- Oil & Gas

Key Projects

Air Quality & Meteorological Modeling

Performed detailed modeling for power plants related to review of licensing projects for the State of Maryland Power Plant Research Program (PPRP) for construction and modification at electrical generating units. These projects involved the preparation of environmental review documents (ERD) in addition to modeling using AERMOD and CALPUFF.

Developed gridded meteorological data using MM5 from various analyzes data for use in various projects including Middle East Countries, Caribbean Islands, and Eastern United States. In addition, performed MM5 runs with various analyses data (FNL, NNRP, GDAS, and ETA) and with or without LSM option and evaluated the runs with onsite meteorology data.

Conducted regional scale modeling analysis using CAMx, SMOKE, AMET, SCICHEM and VERDI for Ozone and PM2.5.

Managed and performed numerous ambient impact analyses including supporting PSD permit applications using AERMOD, and CALPUFF. These analyses included both Class I and Class II area impacts and deposition modeling studies.

Air Quality Permitting Project

Assisted Indiana Department of Environmental Management (IDEM) in the issuance of over 40 air quality permits including construction and operating permits. Reviewed air permits related to refineries, power plants, landfills, auto, and paint manufacturing. Review includes computing source-wide potential emissions for all applicable air pollutants. Responded to all comments/issues received during the public notice period, including comments from the public, and U.S. EPA. Reviewed BACT analyses, NSPS, and NESHAP (40 CFR 60, 61 & 63). Conducting regulatory reviews and compliance assessments with applicable state and federal regulations. Established special operating conditions, testing, record keeping, and reporting requirements. Comprehensive knowledge in control devices like Thermal Oxidizers, Dry Filters, Baghouse, and Scrubber.

Surface Modeling Projects

Developing and automating the collection of input files required to run the ERM's surface water hydrodynamic and oil spill dispersion modules of — GEMSS (Generalized Environmental Modeling System for Surfacewaters). This includes preparing the files in the format required by the model, i.e., netCDF format. In addition, in order to complete the time-critical model runs in an expedited manner, develop algorithms which will assist with transitioning the Windows based GEMSS model runs to a Linux platform. Providing support on the review of existing hydrodynamic models for Gulf of Mexico and setting up models in-house for getting real time high resolution currents for spill modeling.

Assisted in developing and automating comprehensive statistical analyses on the met parameters and pollutants from various data source including WRF and CAMx in netCDF format. In addition, developed in-house statistical tools including wind rose and multi-rose to evaluate various meteorological parameters using SURFER, FORTRAN and shell scripting.

Developed WRF data at higher resolution (148 mt) using the high-resolution (10-meter) geo spatial data for multiple complex terrain regions.

Developed numerous handy tools for WRF, AERMOD and CALPUFF to perform pre and post-processing job using FORTRAN and python.

Anna Sundby, MSc

Socioeconomic Resources/Stakeholder Engagement Specialist

Anna is an experienced and versatile consultant with a background in social performance, communications, and project management. Her expertise includes community and indigenous engagement, land use, livelihoods, impact assessment, and risk management. She is skilled in rapid appraisals and due diligence, as well as comprehensive research and analysis over a project's lifecycle. In addition to consulting activities, Anna has spent extensive periods seconded to clients providing in-house advisory and management services. She has worked across Canada and internationally and is skilled in the application of IFC Performance Standards and other international guidelines. She is comfortable working in politically and culturally complex regions, and works with clients and stakeholders to manage expectations, improve communication, and achieve productive outcomes.

Experience: 13 years' experience in social performance for extractives industries and other sectors.

Key Projects

Facilitator
Managed and facilitated a comprehensive alternatives assessment process for a proposed mine in Yukon, Canada, involving a high level of engagement between the proponent, multiple indigenous groups, and regulatory authorities.

Social Impact Assessment
Managed social, economic, land use, and indigenous baseline studies and impact assessments for a proposed mine in BC, Canada. Also oversaw consultation and engagement programs.

Community-Based Research
Interviewed service providers and land users in remote Arctic communities to support socio-economic and land use impact assessments for a proposed mine in Nunavut.

Technical Oversight and Quality Control
On behalf of the client, provided senior technical review and quality control of social, economic, community health, and land use deliverables for a contentious proposed mine in Canada.

Plain Language Reports
Developed a series of non-technical summary reports describing the expected environmental, socio-economic and health effects of a proposed mine adjacent to a mid-sized city in Canada, including a review of studies completed, management measures, and monitoring programs.

Communities Audit
Completed a community-focused audit for a mine site in Canada. Included commitments from agreements with four indigenous groups and other social risks.

Community Liaison Group
Worked with a mining proponent and municipality to establish a framework and detailed terms of reference for a multi-stakeholder community liaison group to support ongoing engagement and monitoring programs for a sub-urban mine site.

Social and Economic Effects Management Plan
Developed a management plan to address social and economic effects, and community/indigenous engagement, throughout construction and operation of a mine in BC, Canada. Provides regular reports on company and contractor performance.

Due Diligence for Financing and Acquisitions
Led multiple due diligence assessments on behalf of potential investors and buyers, in accordance with international standards and guidelines including IFC Performance Standards and Equator Principles. Includes mining, LNG, and energy assets.

Fisheries Livelihoods Assessment
Assessed potential impacts on fishing activities and livelihoods in relation to a major marine infrastructure project in Nicaragua.

Social Responsibility Advisor
Seconded for two years as an in-house advisor on social responsibility, impact assessment, and stakeholder engagement for a natural gas pipeline through three countries. Provided review and quality control of EIA and ESIA reports for each country. Provided management oversight and quality control.

Construction Management Plans
In Bulgaria, worked with client and contractors to ensure that construction management plans addressed expected socio-economic risks and impacts, and to optimize potential benefits of local employment and procurement.

Stakeholder Engagement Program
For a multi-national pipeline project, developed and implemented stakeholder engagement programs in Bulgaria, Russia and Turkey in collaboration with local consultants. Represented the proponent in public consultation activities, and in meetings with landowners and government.

Social Assessment and Management Plans
Completed a social impact assessment for a proposed power plant in Egypt. Prepared operational management plans related to employment and working conditions.

Social Impact Assessment
Led the social impact assessment for a 700 km rail line associated with a proposed mine in Guinea.

Monitoring and Evaluation
Developed indicators and monitoring measures to evaluate impact and outcomes of a women's economic development NGO activities in East Africa.

Environmental and Social Impact Assessment
Managed the ESIA process for a proposed mine in Greenland. Conducted community-based research to gather socio-economic baseline information. Challenges included remote communities and a relatively new legislative process.

Guidance Note on Community Development Agreements in the Mining Industry
Prepared a guidance note for the World Bank summarizing recent research, best practices, and recommendations related to community development agreements (e.g. IBAs), focused on the mining industry, and aimed at supporting the needs of proponents, governments, and civil society.

Global Stakeholder Management Platform
Worked with a major mining company to develop and implement a web-based system to manage their relationships with government, local communities, indigenous groups, landowners, and other stakeholders. The program was implemented across all of the client's sites worldwide.

Social Responsibility Toolkit
Developed a series of practical and informative social performance tools for site-level staff at a major mining company with global operations. Included thematic and process tools focused on gender, indigenous peoples, social impact assessment, health, stakeholder engagement, and other topics.

Resettlement Framework
Developed a resettlement framework for involuntary land acquisitions associated with a proposed mine, including guidance to ensure the objectives of the IFC Performance Standards are achieved through, and beyond, the government-led expropriation process.

Key Projects Prior to Joining ERM

Stakeholder Engagement and Needs Assessment
Needs assessment and in-country consultation program in Albania engaging government, community members, and employees. Identified potential issues or challenges from government and community perspectives, and ideas for local community investment, capacity building and other benefits. Included an assessment of gender challenges in rural Albania, and consultation with local women's groups.

Land Use Impact Assessment
Evaluated impacts on land users in rural Argentina in relation to a proposed mine and associated transportation and utility infrastructure.

Socio-Economic Impact Assessment
Led the socio-economic and land use assessments for a 350 km transmission line, including nine indigenous groups with varying land claim status. There was a high level of interest in the project, with contrasting priorities for industrial, recreation, and subsistence values. Also coordinated the stakeholder engagement program for this complex project.

Land Use and Livelihoods Study
Conducted workshops and interviews with land users in the Canadian Arctic to understand potential impacts of a proposed mine on land-based livelihoods and subsistence harvesting.

Candice Ramessar

Socioeconomic Resources/Stakeholder Engagement Specialist

Ms. Ramessar is part of ERM Guyana office acting as the Social Team Lead. She has More than 20 years of relevant professional experience as an international consultant in Guyana, Jamaica, St. Vincent & The Grenadines, Barbados, Trinidad and Tobago, Grenada, Antigua, Barbuda, and the United States. Along her career, she had been part of projects related to environmental and social issues including gender equality and mainstreaming. Ms. Ramessar is familiar with the EHS International Guidelines of the World Bank and IFC Performance Standards.

Experience: 20 years' experience in international consulting, environmental and social development, gender equality and environmental and social research in Guyana and across the Caribbean.

Email: Candice.ramessar@erm.com

Key Projects

Applied Political Economy Analysis Consultant
Develop a country strategy for Pact USAID funded project on capacity building of indigenous organizations in Guyana and extractive industries and natural resources management issues.

Stakeholder and Institutional Assessment and Gender Expert
Gender, Social and Institutional Assessment expert for Guyana for the preparation of two UNDP-GEF proposals for USD 20 Million project in mainstreaming biodiversity in small-scale gold mining in Guyana. Conducted Stakeholder Analysis and Gender analysis through Key Informant Interviews etc

Social Specialist World Bank Projects
Ensure compliance of all World Bank-funded projects implemented by the Government of Grenada complies with the World Bank Environmental and Social Operational guidelines. Conduct training and workshops for the government of Grenada staff and local and international contractors

Consultant Results Based Framework
Conducted a two-day workshop on Results-Based Management and facilitation of the planning and development of the Work Plan for the agency for the year 2019. Application of ARC-D toolkit and integration of the Guyana Green State Development Strategy framework for resilient communities

Gender and socio-economic expert
Gender and socio-economic expert for Grenada and St Vincent and the Grenadines for the preparation of two UNDP-GEF proposals for USD 19 Million and 20 Million projects respectively in biodiversity mainstreaming and climate resilient agriculture. Conducted Stakeholder Analysis and Gender analysis through Key Informant Interviews.

Volunteer
Conducted project management and other training for the NGOs and CBOs associated with the Civil Defense Commission as part of the CDC activities to build resilient communities in Guyana and their Community-Based Disaster Management initiatives. Application of the ARC-D toolkit.

Consultant
Conduct an assessment of the users and holders of Biodiversity information including a needs assessment and a capacity development strategy.

Women and Child/Social Inclusive Expert
Designed and developed 10 children friendly regional profiles to be used by the Civil Defense Commission for the Ministry of Communities and the Civil Defense Commission in climate-smart and disaster planning for the 10 regions of Guyana using the data and indicators from the 2016 MICS Survey.

Environmental Sociologist
Conducted socio-economic analysis including gender analysis of the Rio Conventions implementation in Guyana (United Nations Convention on Climate Change, Desertification, and Biodiversity). Design and implement a national KAP survey to assess the perceptions of the public to the conventions. Conducted an assessment of the awareness of the Rio Conventions in 28 Governmental Agencies in Guyana.

Consultant Social Specialist
Serves as the social consultant for World Bank-funded projects at the Ministry of Agriculture, Guyana. Responsible for the implementation of social safeguards according to World Bank OP guidelines, including voluntary resettlement. Develop and implement a monitoring framework and collect baseline social indicators. Monitor social indicators.

Social Consultant
Part of a team that conducted an -ex-ante economic analysis of a USD 20 Million IDB housing project in

Sophia, Guyana. Served as the environmental/social consultant. Conducted Key Informant Interviews and provided social indicators in the development of the economic analysis tool.

National Researcher/Consultant Women
Researcher for a National Qualitative Study on Indigenous Women and Children in Guyana. Conducted focus groups, key informant interviews, and individual profiles in 20 indigenous hinterland communities across Guyana.

Gender Environmental and Social Consultant
Safeguards Consultant for the development of a stakeholder engagement plan, indigenous peoples plan and gender plan for a GEF 3.5 million USD project on the elimination of mercury in small-scale gold mining in Guyana.

Socio-economic and Gender Consultant
Conducted a rapid socio-economic impact assessment including a gender analysis of the Caribbean Marine Bio-diversity Project on the fisherfolk in the islands of St. Vincent and the Grenadines and Grenada

Researcher, Social Analysis
Prepared three country reports for Guyana, Saint Vincent and the Grenadines and Suriname on the HDI indices, institutional, gender and human capacities of the Water and Sanitation (WASH) sector in the respective countries. Interviewed key governmental officials in the water, health, and education sectors.

National Project Consultant
Consultant in the Sustainable Financing and Management of Eastern Caribbean Marine Ecosystems Project. Guided all the activities of the project especially the development of a conservation trust fund for funding of environmental NGOs by providing technical support, including baseline assessment of financing, sustainable finance options and the development of a business model. Collaborated closely with other project consultants, the NIE within the government of Saint Vincent and the Grenadines, the project focal point within the NIE, and other government, regional and international partners and stakeholders. Carried out gender and vulnerability analysis.

Consultant Environmental Communications
Designed and implemented a 7-day workshop and modules on Environmental Awareness and Communications for the staff of the Ministry of Agriculture and Rural Development of Saint Vincent and the Grenadines

Social and Gender Consultant
Georgetown Solid Waste Project/ Social Development Specialist as part of the study of an Environmental and Social Audit of the Haggs Bosch landfill; Eccles. Using PRA methodologies researched, analyzed, and present the findings, including a gender analysis of the impacts of the landfill on the surrounding communities. Data were analyzed using SPSS and differentiated impacts by gender calculated.

Consultant on Communications for Development
Developed and implemented a 5 module Communication for Development Programme for the farmers of the Peter's Hope Bordisen area in Saint Vincent and the Grenadines.

Social sector Consultant Project Management
Sustainable Grenadines GEF Civil Society Capacity Building Project Developed a toolkit for civil society organizations in SVG on Basic Project Management including data management and use of project management software. Conduct two-day training on Project Management for CSOs.

Consultant on Communications and Knowledge Management
Developed a toolkit for civil society organizations in SVG on Monitoring and Evaluation, Communications and Knowledge Management. Conduct two-day

training on M& E-communications and Knowledge Management for CSOs.

Consultant in gender in a DRM project
Conducted a vulnerability assessment of the agriculture sector of SVG including gender and social analysis using PRA methodologies and other qualitative tools. Major stakeholders included female farmers, farmers' association's cooperatives, NGOs and governmental bodies. Developed a methodological tool for the assessment of vulnerability. The gender dimensions of vulnerability were noted and actions to address impacts were recommended.

Consultant, Project manager
Served as the consultant and project manager for an IDB Funded Caribbean project targeting the capacity building and institutional strengthening of consumer organizations in three Caribbean countries, Jamaica, Trinidad, and Tobago, and Barbados. Reported to the Director of Global Operations and was responsible for all aspects of the project including financial management.

Social Specialist
Facilitated, designed and coordinated a Social Monitoring Study of Rose Place, Kingstown, Saint Vincent in collaboration with the Ministry of Agriculture and Fisheries and the fishermen society. Designed a qualitative study, coordinated interviewers and the collection of data, analyzed primary data using SPSS to produce a final document.

Consultant
Designed Public Awareness and Promotional materials for the Environmental Health Division of the Ministry of Health and Environment St Vincent and the Grenadines

Consultant in DRM
Designed and conducted a desk study on the status of and debate and actions on Community Disaster Management (CDM) in the Caribbean and recommendations for a workshop on Farmers Association and CDM in the Caribbean region.

Consultant
Prepared two modules and conducted two workshops on Solid Waste Management and Corporate Citizenship in Kingstown, SVG

Consultant
Prepared a Strategic Plan for the Caribbean Farmers Network for the years 2008-2010 and an Action Plan for the year 2008.

Volunteer Natural Resources Management Expert
Conducted research on areas such as the World Trading Organization, Economic Partnership Agreements, Served as Technical Adviser to several Agricultural Projects on Sustainable Agriculture and Climate Change

Adjunct Professor
Taught a senior level class of Human Geography to final year undergrad students.

Science Teacher
Taught 9th and 10-grade environmental science classes per New Jersey Core Curriculum in Biology and Physical science

Teaching Assistant
Taught undergrad classes in Environmental and Physical Geography, served as an Assistant to several Professors, also gave guest lectures on Caribbean environmental and social issues.

Program Officer
Designed and Implemented a one-year USAID funded programme to increase the political participation of women, youth and indigenous peoples in various aspects of governance in Guyana including capacity building of the organizations.

Director
Co-Founded and managed an environmental organization in Guyana focused on watershed issues particularly a cyanide spill in the Essequibo River. Research projects for GREEN were funded by several international organizations including the IUCN. The advocacy work of the organization was also featured in several international media outlets including German Public TV.

Cross-Cultural Facilitator
Conducted training exercises with new volunteers on Guyanese society particularly on topics of Guyanese women, African Guyanese, local geography and local dialect.

Technical Assistant to the Minister
Designed, implemented, and monitored and evaluated projects for women's groups and organizations across Guyana. Served as a contact with the press for the Women Affairs Bureau and the Ministry of Labour in Guyana. Represented the government minister at meetings.

SERVING PEOPLE FOR DEVELOPMENT. GUIDED BY PRINCIPLES OF: HONESTY; INTEGRITY; RESPECT; DIGNITY; AND TRANSPARENCY

SUMMARY OF KEY COMPETENCIES

COMPETENCE	EXPERTISE	YEARS OF EXPERIENCE
Programme Management	Managing programmes that promote community resilience using integrated programming models. Focus areas: Gender; Health - Sexual and Reproductive Health (SRH), HIV and STI prevention, Non-Communicable Diseases, Vector-borne Diseases, First Aid; Disaster Risk Reduction and Management; Youth Development. Water and Sanitation. Leadership Capacity Development	18 years
Planning, Monitoring, Evaluation and Reporting (PMER)	Developing Monitoring and Evaluation frameworks for projects/programmes. Designing monitoring, evaluation and reporting tools. Training practitioners. Designing and implementing assessments and evaluations including but not limited to: performance appraisals, capacity assessments, impact evaluations, satisfaction surveys, Gap Analysis.	16 years
Facilitation (Facilitator, Trainer of Trainers and Coach)	Development of agenda using pedagogical and participatory approaches, coordination and facilitation of community, national, regional, and global level workshops, conferences, training, meetings, consultations, and other fora. Trainer of trainers (TOT)	18 years
Community Life Competence (CLC) Facilitator and Coach	Integrating CLC into community programming to identify and maximize strengths, capacities, and resources by harmonizing vision, conducting self and situation assessments, and developing action plans to achieve community goals	12 years
Designing for Behaviour Change (DBC)	Designing programmes using Social and Behaviour Change Communication (SBCC) models. Integrating behaviour change models in program implementation. Providing training for programme planners and implementers. Designing M&E tools for measuring change	8 years
Project/Programme Planning Process - Trainer of Trainers, Facilitator and Coach	Conducting certificate training adapted for Community Leaders, Civil Society groups, programme implementers, youth organizations, other institutions and agencies; enabling them to identify and analyze issues, develop strategies for comprehensively addressing them, and designing projects/programmes for implementation.	16 years

KEY ROLES/PROFESSIONAL EXPERIENCE

CONSULTANT: SOCIAL SPECIALIST – DEVELOPMENT OF THE LINDEN-MABURA HILL SOCIAL IMPACT AND GENDER ANALYSIS, NOVEMBER 2020 – JANUARY 2021

Supported the process by conducting stakeholder and community consultations for updating the feasibility study and prepare detailed designs for the Linden-Mabura Hill Road upgrade and bridge at Kurupukari through a review of the existing studies and undertake the necessary surveys, studies, analysis and designs. Contributed to the preparation of tender documents for the upgrade of the Linden-Mabura Hill Road and bridge at Kurupukari inclusive of, but not limited to, final detailed designs, bills of quantities, environmental and social impact assessment and management plan, technical specifications and conditions of contract. Specifically produced; revised Environmental and Social Impact Assessment (ESIA), and revised Environmental and Social Management Plan (ESMP).

PROJECT COMMUNITY LIAISON OFFICER/SOCIAL SPECIALIST – SHERIFF STREET MANDELA AVENUE ROAD EXPANSION PROJECT, FEBRUARY 2020 – PRESENT

Provide construction management, contract administration and resident engineering services to the Works Services Group of the Ministry of Public Infrastructure for the Implementation of the Sheriff Street – Mandela Avenue (SSMA) Roadway Enhancement Project funded by the Inter-American Development Bank (IDB). Implemented all activities and tasks outlined in the project's Stakeholder Engagement Plan (SEP). Provided oversight for the implementation of the social aspects of the project Environmental and Social Management Plan (ESMP). Coordinated and conducted quarterly frequent stakeholder consultation meetings to discuss all social and environmental issues on the project. Continuously monitored the conduct of workers towards neighbouring communities and the quality of the social engagement activities of the Contractor. Investigated and solved issues raised by communities related to abuses, violations and conflicts caused by the behaviour of workers and other construction activity (e.g., traffic, accidents with victims, dust, property damage, conflicts with communities, etc.).

CONSULTANT: TEAM LEADER – GENDER AND SOCIAL ANALYSIS, GEF-GOLD PROJECT, CONSERVATION INTERNATIONAL-GUYANA (CI), AUGUST 2019 – APRIL 2020

Lead the process of designing process, methodology and tools, and conducted a baseline gender and social
assessment to evaluate participation and contribution in the gold value chain. The assessment specifically identified and examined gender roles in the artisanal and small-scale gold mining value chain, with specific emphasis on constraints and opportunities for participation, livelihood options and income generation; evaluated awareness about the use, handling and effects of mercury on humans and the environment;
and assessed local interest, and potential incentives, for the transition towards more responsible use of mercury and mercury free approaches.

CONSULTANT: NATIONAL GREEN STATE DEVELOPMENT STRATEGY (GSDS) CONSULTATIONS, WWF GUIANAS CONTRACTED. JUNE, DECEMBER 2018

Facilitated planning and execution of national consultation processes conducted in Regions 1, 2, 7, 8, 9, and 10. Included leading preparation of detailed, well-designed consultation process document. Lead and facilitated consultation process at cluster locations according to plan. Ensured meaningful stakeholder engagement and inputs. Compiled regional reports. Analyzed data and drafted recommendations for the Green State Development Strategy

ORGANIZATIONAL DEVELOPMENT CONSULTANT: NATIONAL SOCIETY DEVELOPMENT, INTERNATIONAL FEDERATION OF RED CROSS RED CRESCENT. FEBRUARY – MAY 2018

Provided support to the thirteen Red Cross National Societies (Red Cross organizations) of the Caribbean in updating and modernizing their way of operating by primarily addressing internal pressures related to the areas of National Society leadership, integrity, accountability, development strategy, financial sustainability and internal reforms. This included related development areas such as Learning and Innovation, Federation Data Reporting Systems and Volunteering and Youth Development as prescribed in the Development Operational Plan.

CAPACITY DEVELOPMENT CONSULTANT: NORTH RUPUNUNI DISTRICT DEVELOPMENT BOARD AND SOUTH CENTRAL PEOPLES DEVELOPMENT ASSOCIATION CAPACITY BUILDING, WWF GUIANAS CONTRACTED. NOVEMBER – DECEMBER 2017

Designed and facilitate capacity building training with the North Rupununi District Development Board (NRDDB), South Central Peoples Development Association (SCPDA) Leadership and Community Monitors, and other direct and indirect project partners of the WWF SRJS Project.

AUTHOR: INTERNATIONAL RED CROSS RED CRESCENT GLOBAL YOUTH ENGAGEMENT STUDY REPORT 2017. AUGUST – DECEMBER 2017

Analyzed findings of the Global Youth Engagement Study of 2017 (122 National Societies /Countries participated), and wrote a comprehensive report: "IFRC Global Youth Engagement Study Report 2017". conducted a comparative analysis of the 2017 findings with those of the 2015 Global Report, and produced recommendations for improving and increasing meaningful youth engagement in the context of 'youth as leaders, 'youth as members of affected communities' and 'youth as volunteers.'

CONSULTANT: GENDER MAINSTREAMING AND INCLUSIVENESS WORKSHOPS, WWF GUIANAS AND IUCN GLOBAL GENDER OFFICE. NOVEMBER 2017 AND JUNE 2019

Coordinated, design methodology, and facilitated Gender Mainstreaming and Inclusiveness Workshop. Prepared substantive content for learning sessions covering the topics Gender, Intersectionality, Diversity and Mainstreaming; Rights based approach for environmental governance; and gender and inclusiveness.

CAPACITY DEVELOPMENT CONSULTANT: SOUTH CENTRAL PEOPLES DEVELOPMENT ASSOCIATION, CAPACITY DEVELOPMENT OF MONITORS - WWF GUIANAS. AUGUST 2017

Designed, prepared materials for and facilitated capacity development exercise to support SCPDA by training Community Monitors and technical/project staff in the areas behavioural change communication and advocacy communication, addressing issues such as mining impacts on environment and human health and legislation (natural resources and environmental management).

PROGRAMME MANAGER: BUILDING RESILIENT COMMUNITIES IN REGIONS 1 AND 7, GUYANA RED CROSS SOCIETY. 2013-2017

Lead a team of 15 persons on the strengthening community resilience programme. Specifically to: Lead the process of adopting new ways of strategically engaging key stakeholders and build alliances at grass root levels. Transformed the involvement of the programme in addressing community vulnerabilities by transitioning from a position of ‘project experts’ to one of partners and facilitators of comprehensive and holistic approaches intended to: a. foster cohesiveness within communities; b. build capacity of local leadership to identify, analyze, and respond to challenges; c. increase dialogue for greater connectedness; d. provide technical expertise in specific areas of vulnerability in an integrated manner; e. train community members as resources in diverse sector specific disciplines; and f. build alliances

with local and external partners increasing the impact of the programme. The programme directly reached over ten thousand people and indirectly impacted many more.

OTHER ROLES

FACILITATOR: EXCHANGE MEETING ON COMMUNITY MONITORING REPORTING AND VERIFICATION – NORTH RUPUNUNI DISTRICT DEVELOPMENT BOARD AND KANUKU MOUNTAINS COMMUNITY REPRESENTATIVE GROUP --- REGION 9, WWF GUIANAS CONTRACTED. 2017

FACILITATOR (WWF GUIANAS): STAKEHOLDER MEETING "PROMOTING INTEGRATED AND PARTICIPATORY OCEAN GOVERNANCE IN GUYANA AND SURINAME: THE EASTERN GATE TO THE CARIBBEAN" - GEORGETOWN, GUYANA. 2017

EVALUATOR (THE CONSULTANCY GROUP - TCG): POST ASSIGNMENT EVALUATION OF CI-IDB BASELINE FARM SURVEY. 2015

NATIONAL PROGRAMME MANAGER: CARIBBEAN HIV AND AIDS PREVENTION PROJECT FOR 'AT-RISK' POPULATIONS - REGIONS 1 AND 7, GUYANA RED CROSS SOCIETY. 2010 – 2013

FIELD MANAGER (USAID/PEPFAR): HIV AND AIDS PROGRAMME INITIATION MANAGER - REGIONS 1, 4 AND 9, 2004-2010

PROJECT MANAGER (WORLD BANK): REGIONS 1, 4, AND 10. 2006 - 2010

FIRST AID (FA) COORDINATOR, NATIONAL, 2002-2004

EDUCATION

St. Ignatius Secondary School
Dip. Public Management, University of Guyana
BSc. Sociology, University of Guyana
Certificate – Youth Leadership, Commonwealth Youth Programme
Certificate – Programme Management in Development (PMD Pro), APMG International Certificate
Certificate - Community Engagement and Accountability (IFRC)
Certificate - Project/Programme Planning Process (Programme Development)

Amanda Sahai–Alli

Social Specialist

42 Houston Gardens,
Georgetown, Guyana
Mobile: 592–6716343/Email:
Amanda.sahai@hotmail.com

PROFILE

Dynamic, hardworking and detail-oriented professional with over ten years' experience engaging members of diverse communities, government agencies and private sector organisations to effectively and efficiently build and maintain cross-functional relationships that contribute to capacity building, community development, and client health and wellness. Works independently with minimal oversight to prioritize tasks and meet tight deadlines in high-pressure environments. Adept in conducting research and synthesizing large volumes of information into concise and informative reports.

CORE COMPETENCIES

- ❖ Stakeholder Engagement
- ❖ Project Management
- ❖ Statistical Package for Social Sciences
- ❖ Research
- ❖ Logistics
- ❖ Monitoring & Evaluation
- ❖ Social Impact Assessment
- ❖ Mental Health

Computer Skills: Microsoft Office Suite

EDUCATION

- **Master of Science (Public Health),** University of Bedfordshire, London, England, 2019–2021
- **Bachelor of Science in Social Work**, University of Guyana, Turkeyen, Guyana, 2005–2007
- **Diploma in Social Work**, University of Guyana, Turkeyen, Guyana, 2003–2005

CERTIFICATION

- Corona Virus Workforce Preparedness Training, Corporate Health and Wellness Association, October 2020
- Certified Training in Statistical Package for Social Sciences (SPSS), Nations University, July 2020
- Certificate in Psychological First Aid for Children (A&B) and Worker Care Module 1, Guyana Red Cross Society, February 2008

PROFESSIONAL EXPERIENCE

March 2017 –Present **Social Work Consultant**
Panacea Consulting

Provide Employee Assistant Programme (EAP) services to organisations in the public and private sectors of Guyana to help employees manage life-stressors of various kinds. The services offered include:

- individual counseling through the practice of social work
- interactive group sessions on mental health awareness
- corporate wellness and pertinent social issues
- corporate social responsibility and
- social impact assessments for projects

February 2008–2011 **Project Manager**

Health Sector Development Unit, Ministry of Health

- Provided oversight of projects managed by the Health Sector Development Unit particularly budget preparation and addressing implementation issues for Human Resource Management Information System Project and other donor funded projects.
- Provided capacity building support for Civil Society Organizations in Project Management.
- Participated in the formulation of the National Mental Health Strategic Plan (2008-2012) including addressing gaps in the then Mental Health Legislation.

Monitoring & Evaluation Officer

Health Sector Development Unit, Ministry of Health

- Responsible for the monitoring of IDB, World Bank and Global Fund Projects including the Basic Nutrition Programme, Guyana HIV/AIDS Reduction Project, the Global Fund Malaria and Tuberculosis Projects.
- Assisted in the adaptation of M&E Tools by Civil Society Organizations and Line Ministries implementing HIV interventions in Guyana.

Assistance Mental Health Coordinator

Health Sector Development Unit, Ministry of Health

- Facilitated workshops under Programme including "Enhancing the Capacity of First Responders to Provide Therapeutic Psychosocial and Basic Mental Health Interventions to Children Affected by Trauma".
- Served on National Suicide Prevention Committee.
- Represented Ministry of Health on "Mental Health and Media Reporting" forum organized by the Ministry of Health in

collaboration with the IDB and the Pan American Health Organization.
- Participated in the preparation and planning of the Treatment and Rehabilitation Program for Substance Abusers in Guyana.
- Planned and executed several psychosocial interventions in the Lusignan Community, Bartica Community and Linden Region.

VOLUNTARY WORK

- Current Director of Public Relations, Rotary Club of Garden City Georgetown Guyana
- Volunteer Counselor with Guyana Foundation , 2012 - 2016
- Member and Social Worker for the Central Islamic Organization of Guyana (CIOG) Medical Outreach Committee, 2008 – 2010
- "Humanitarian Assistance Program" (HAP); which included workshops and seminars [US Embassy Office – Georgetown, Guyana], July 2007
- Community Service Work with the Transfiguration Church, August 2005

1. INTRODUCTION

1.1 Purpose

In support of an Environmental Impact Assessment (EIA) for the proposed Yellowtail Development Project (Project), Esso Exploration and Production Guyana Limited (EEPGL) commissioned Environmental Resources Management (ERM) to perform modeling of discharges into the marine environment related to planned drilling and oil production in the Stabroek Petroleum Prospecting License Area offshore Guyana (Stabroek Block; Figure 1-1). This modeling included simulations of drill cuttings and mud deposition; and discharges of cooling water; sulfate removal, ultrafiltration, and wash water processing brines; produced water; and hydrotest fluid. Additionally, modeling was performed for a potential unplanned event comprising the hypothetical release of untreated black water from the Project's proposed floating production, storage, and offloading (FPSO) vessel.

1.2 Scope of Work and Report Organization

This technical report describes the modeling study performed to facilitate assessment of the potential impacts from planned offshore releases and one unplanned offshore release. Section 2 describes modeling performed for planned discharges related to drilling operations; Section 3 describes modeling performed for planned discharges related to production operations, as well as modeling performed for an unplanned release of untreated wastewater (black water) from the Project FPSO. Because the planned activities of the Project will overlap with the planned activities of other EEPGL projects in the Stabroek Block, Sections 4 and 5 describe modeling performed for the combined (cumulative) activities of the Project along with those of the Liza Phase 1, Liza Phase 2, and Payara Development Projects.

Computational models were used to estimate the fate and transport of Project-related discharges. Input data for the modeling were selected based on review of available Project design information, review of oceanographic data from the Project Development Area vicinity, and use of conservative assumptions where data were not available.

Results from modeling conducted for unplanned oil spill scenarios are provided under separate cover in an Oil Spill Response Plan prepared in support of EEPGL's offshore activities in Guyana.

km = kilometer

2. DRILL CUTTINGS AND MUD DEPOSITION MODELING

2.1 Approach

In this section, the planned discharge of drill cuttings is evaluated. It is assumed that there will be a direct discharge (i.e., near the seabed) of cuttings with water-based drilling fluids during drilling of the riserless open-hole section at each well and, for all other well sections, a discharge near the sea surface of cuttings from material removed in the lower well sections plus a small fraction of adhered residual non-aqueous drilling fluid (NADF) after treatment on the FPSO.

Modeling was performed to predict the following as a result of cuttings discharge:

- The total suspended solids (TSS) concentrations in the water column;
- The accumulation (thickness) of the adhered muds and drill cuttings on the seafloor; and
- The mass of hydrocarbons settled upon the seafloor.

2.1.1 Scenario Design

Released material will pass vertically through the water column because cuttings and muds are denser than the receiving water. Released material will also migrate horizontally due to advection by local and regional currents. The dispersion of cuttings and muds is fundamentally a three-dimensional (3-D) phenomenon requiring 3-D hydrodynamic fate and transport modeling.

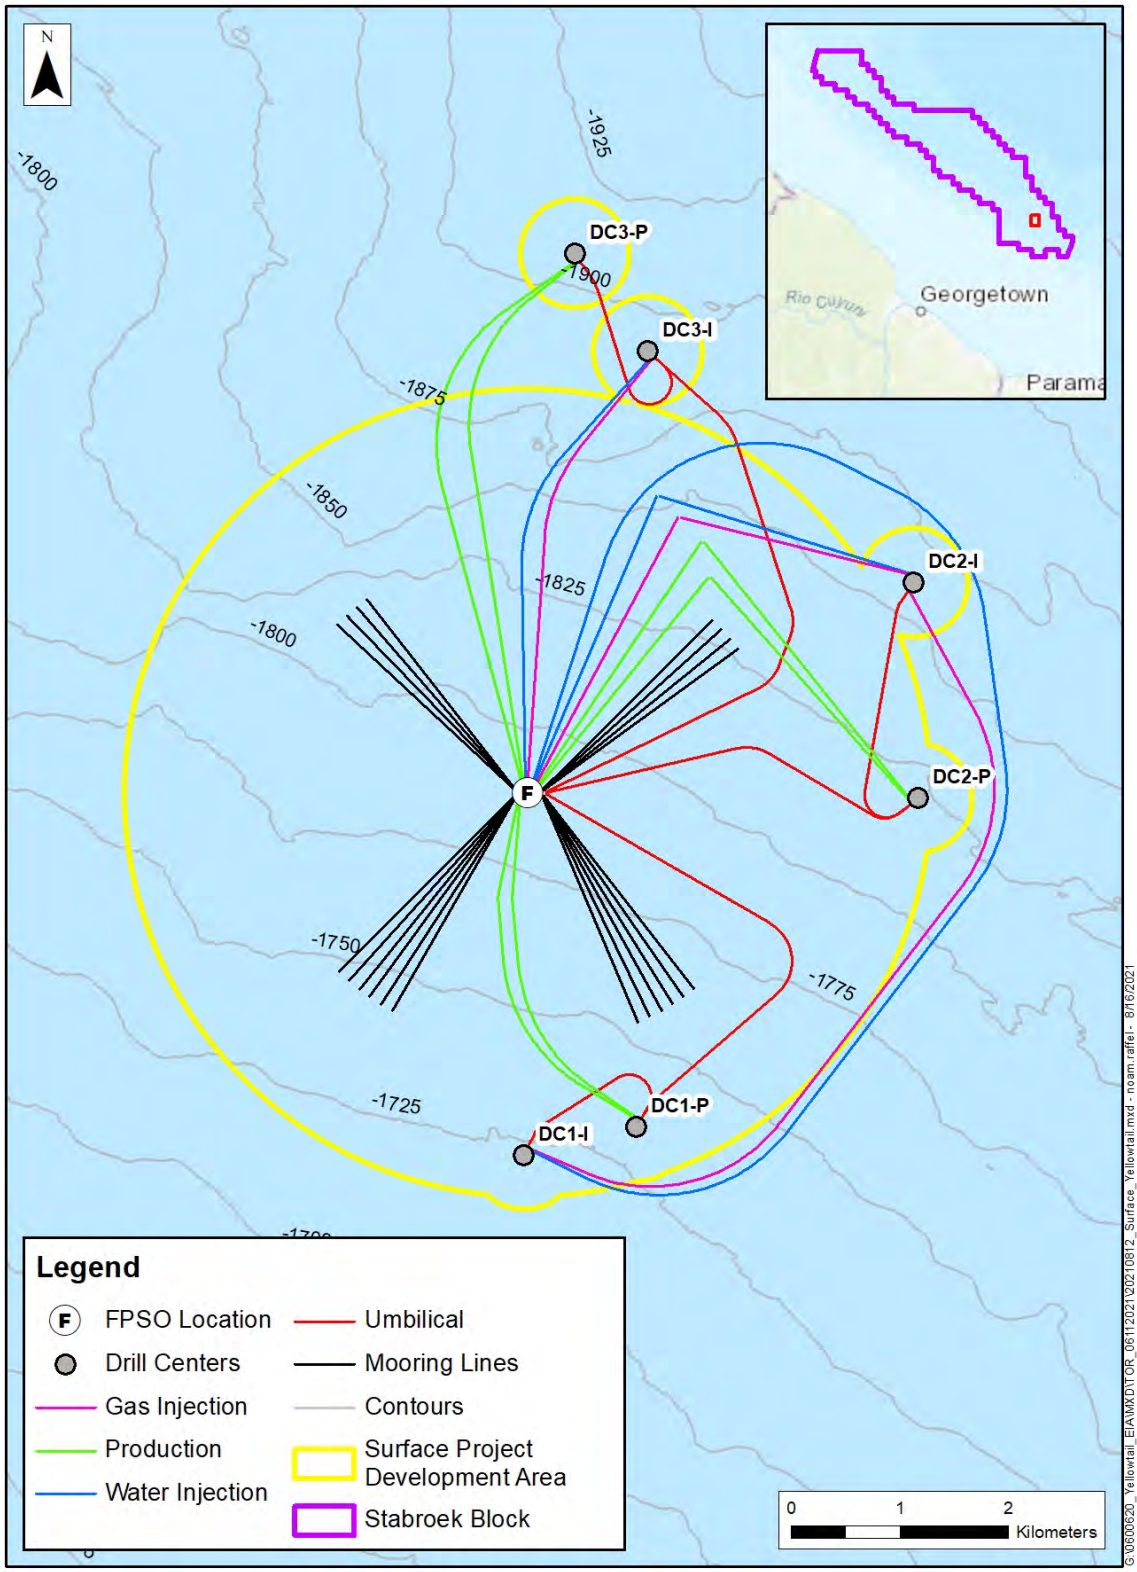
For modeling purposes, two drill center locations were selected at extreme ends of the range of water depths across the Project drill centers (see Figure 2-1). Location DC1-I represents an injection well cluster at drill center DC1-I, and location DC3-P represents a production well cluster at drill center DC3-P. Coordinates of the drill centers and the approximate depths of water at these locations are presented in Table 2-1.

Table 2-1: Modeled Drill Center Locations and Water Depths

Drill Center Location	Longitude	Latitude	X Coordinate in UTM 21N (meters)	Y Coordinate in UTM 21N (meters)	Water Depth (meters)
DC1-I	-56.7168	7.9272	531,218.4	876,268.4	1,723
DC3-P	-56.7122	8.0019	531,720.6	884,520.0	1,910

UTM = Universal Transverse Mercator

Figure 2-1: Locations of Planned Drill Centers in the Yellowtail Project Development Area



2.1.1.1 Location DC1-I

For modeling purposes, it is assumed that a cluster of four wells will be drilled within <20 meters (65.6 feet) of the drill center at DC1-I. Each well will consist of five sections. At each of these well locations, the top hole (Section 1) and conductor (Section 2) will be jetted and drilled with water-based muds (WBM) to a depth of 1,540 meters (5,052.5 feet) below the mud line. The subsequent three sections—with hole diameters of 44.5 centimeters (17.5 inches), 31.1 centimeters (12.25 inches), and 24.1 centimeters (9.5 inches)—will be drilled with NADF until a total depth of approximately 6,090 meters (19,980 feet) below the mud line is reached. Details of these sections are presented in Table 2-2. The discharge pipe from the drill ship is assumed to release treated cuttings from Sections 3 through 5 at a depth of 11 meters (36 feet) below mean sea level.

Table 2-2: Well Profile at Location DC1-I

Section	Diameter, millimeters (inches)	Section Length, meters (feet)	Modeled Cuttings Discharge Duration (days)
Section 1—Structural (Top Hole, Jet)	914.4 (36)	120 (393.7)	0.5
Section 2—Conductor	711.2 (28)	1,420 (4,658.8)	1.6
Section 3—Surface	444.5 (17 ½)	950 (3,116.8)	3.5
Section 4—Production	311.2 (12 ¼)	2,550 (8,366.1)	8.1
Section 5—Open	241.3 (9 ½)	1,050 (3,444.9)	6.8

2.1.1.2 Location DC3-P

For modeling purposes, it is assumed that a cluster of four wells will be drilled within <20 meters (65.6 feet) of the drill center at DC3-P. Each well will consist of five sections. At each of these well locations, the top hole (Section 1) and conductor (Section 2) will be jetted and drilled with WBM to a depth of 1,430 meters (4,691.6 feet) below the mud line. The subsequent three sections—with hole diameters of 44.5 centimeters (17.5 inches), 31.1 centimeters (12.25 inches), and 24.1 centimeters (9.5 inches)—will be drilled with NADF until a total depth of approximately 6,070 meters (19,914.7 feet) below the mud line is reached. Details of these sections are presented in Table 2-3. The discharge pipe from the drill platform is assumed to release treated cuttings from Section 3 through 5 at a depth of 11 meters (36.1 feet) below mean sea level.

Table 2-3: Well Profile at Location DC3-P

Section	Diameter millimeters (inches)	Section Length, meters (feet)	Modeled Cuttings Discharge Duration (days)
Section 1—Structural (Top Hole, Jet)	914.4 (36)	130 (426.5)	0.5
Section 2—Conductor	711.2 (28)	1,300 (4,265.1)	1.6
Section 3—Surface	444.5 (17 ½)	930 (3,051.2)	3.5
Section 4—Production	311.2 (12 ¼)	2,670 (8,759.8)	8.1
Section 5—Open	241.3 (9 ½)	1,040 (3,412.1)	6.8

2.1.1.3 Model Scenarios

The model simulations for drill cuttings discharges included three scenarios at each drill center location. These are described below.

Scenario 1

Scenario 1 evaluated the impacts from sequentially jetting and drilling two top-hole sections (Sections 1 and 2) at each of the four well locations at DC1-I and DC3-P. This represents the most likely maximum number of top holes (eight; four wells with two top-hole sections each) that could be drilled sequentially at any time from a drill center (DC1-I or DC3-P) within a 30-day time period (the time period relevant for the 5 centimeters (2 inches) per month deposition threshold used). Table 2-2 and Table 2-3 show that the predicted drilling durations based on continuous drilling are 0.5 day and 1.6 days for Section 1 and Section 2, respectively. However, from an operational standpoint, the total duration of the jetting/drilling of these top-hole sections (Sections 1 and 2) will each take approximately 1 week, considering breaks and labor shifts. In addition, jetting/drilling of any top-hole section (Sections 1 and 2) will be followed by at least a 4-day rest period prior to starting the jetting/drilling of the next top-hole. Considering these breaks and rest periods, in addition to the actual drilling/jetting period, this results in a total operational period of 40 days for all four locations, with two top-hole sections at each location.

The resting/break period of 4 days between the sections and wells will allow releases to settle without initiation of a new release from a subsequent well. For conservativeness in the model, the model simulations assumed only a 1-day resting/break period, while preserving the actual continuous drilling duration. This conservative assumption significantly compresses the overall drilling schedule from a total of 40 days to a total of 19 days. The modeled drilling schedule is shown in Table 2-4.

Table 2-4: Scenario 1 Simulation Schedule

Drilling Action	Duration (days)
Well 1—Section 1	0.5
Break	1
Well 1—Section 2	1.6
Break	1
Well 2—Section 1	0.5
Break	1
Well 2—Section 2	1.6
Break	1
Well 3—Section 1	0.5
Break	1
Well 3—Section 2	1.6
Break	1
Well 4—Section 1	0.5
Break	1
Well 4—Section 2	1.6
Additional Modeled Period for Particle Settling	3.6
Total Simulation Days	**19**

Scenario 2

Scenario 2 evaluated the sequential jetting and drilling of two top-hole sections (Sections 1 and 2) at two of the drill center locations (DC1-I and DC3-P) followed by the change-out of the drill ship to NADF drilling and the drilling of Sections 3 and 4 at the second drill center location for which top-hole sections were drilled. This represents the most likely maximum number of top holes (two wells with two top-hole sections each) and bottom holes (one well with two bottom-hole sections) that could be drilled sequentially at any time from a drill center (DC1-I or DC3-P) within a 30-day time period (the time period relevant for the 5 centimeters (2 inches) per month deposition threshold used). Table 2-2 and Table 2-3

show that the actual predicted drilling durations based on continuous drilling are 0.5 days and 1.6 days for Section 1 and Section 2, respectively. Actual predicted drilling duration based on continuous drilling is 3.5 days for Section 3 and 8.1 days for Section 4. However, from an operational standpoint, the total duration of the jetting/drilling operation of these top-hole sections (Sections 1 or 2) will take approximately 1 week, considering breaks and labor shifts. Once the top-hole sections of the second well have been drilled (approximately 7 days), WBM drilling equipment will be changed to NADF equipment over a rest period of approximately 7 days. Following this change out, Sections 3 and 4 of the second well will be drilled over a period of approximately 15 days. Considering these breaks and rest periods, in addition to actual drilling/jetting period, this results in a total operation period of approximately 40 days.

The resting/break period of 4 to 7 days between the sections and wells will allow releases to settle without any new release starting from the subsequent section. For conservativeness in the model, the model simulations only assumed a 1-day resting/break period, while preserving the actual continuous drilling duration. This conservative assumption significantly compresses the overall drilling schedule from a total of 40 days to a total of 21.5 days. The modeled drilling schedule is shown in Table 2-5.

Table 2-5: Scenario 2 Simulation Schedule

Drilling Action	Duration (days)
Well 1—Section 1	0.5
Break	1
Well 1—Section 2	1.6
Break	1
Well 2—Section 1	0.5
Break	1
Well 2—Section 2	1.6
Break	1
Well 2—Section 3	3.5
Break	1
Well 2—Section 4	8.1
Additional Modeled Period for Particle Settling	0.7
Total Simulation Days	**21.5**

Scenario 3

Scenario 3 assesses hydrocarbon deposition from topside discharges of treated drill cuttings with adhered NADF from sequentially drilling three bottom-hole sections (Sections 3, 4, and 5) at each of four well locations at a drill center. Table 2-2 and Table 2-3 show that the actual drilling durations based on continuous drilling are 3.5 days, 8.1 days, and 6.8 days for Section 3, 4, and 5, respectively. However, from an operational standpoint, the drilling of Sections 3 through 5 of a well would likely extend over a period of approximately 25 days, followed by a period of approximately 14 days before beginning drilling of Sections 3 through 5 of a subsequent well. The drilling of Sections 3 through 5 of the subsequent well will require another approximately 25 days to complete, followed by a period of approximately 14 days before drilling the next well's bottom-hole sections. Drilling of the third and fourth wells will take another approximately 64 days. In total, it is estimated that this drilling operation would take approximately 140 days.

The resting/break period ranging from 4 to 7 days to multiple weeks between the sections and wells will allow releases to settle without any new release initiating. For conservativeness in the model, the model simulations only assume a 1-day resting/break period while preserving the actual continuous drilling

duration. This conservative assumption significantly compresses the overall drilling schedule from a total of more than 140 days to a total of 87 days. The modeled drilling schedule is shown in Table 2-6.

Table 2-6: Scenario 3 Simulation Schedule

Drilling Action	Duration (days)
Well 1—Section 3	3.5

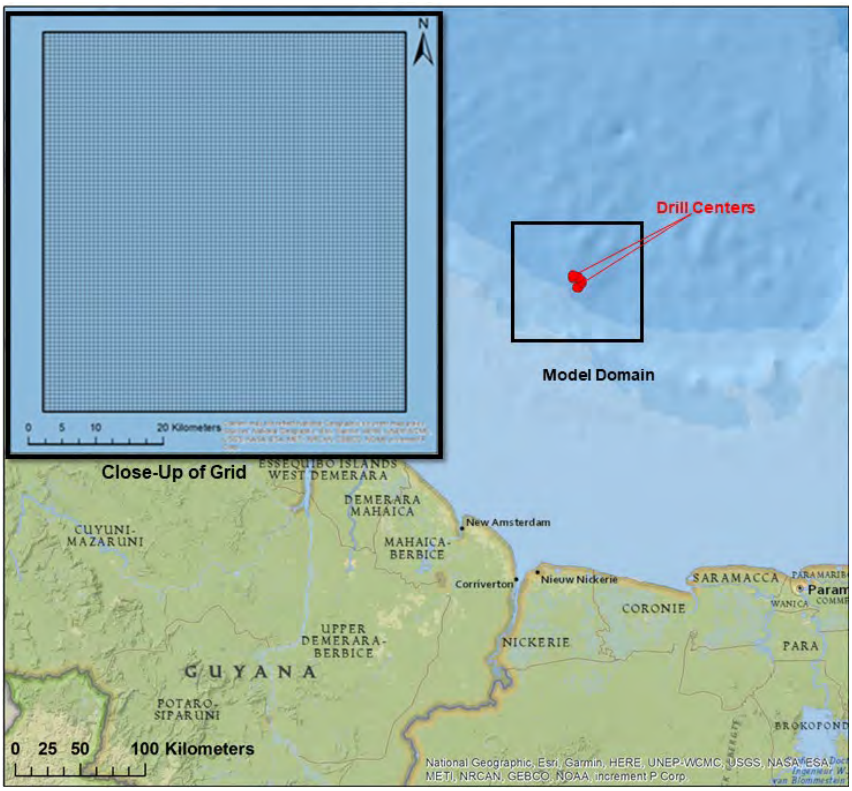
Additional Modeled Period for Particle Settling	2.4
Total Simulation Days	**87**

2.1.1.4 Particle Grids

Three model grids were used: a particle grid, a depositional grid, and a concentration grid. The movement of the discharged cuttings and muds using Lagrangian particles was computed within the particle grid (Figure 2-2). This particle grid is a square approximately 50 kilometers (31 miles) on each side, with each cell approximately 50 meters (164 feet) by 50 meters (164 feet). Each grid cell contains an interpolated depth value derived from the bathymetry data described in Section 2.1.3.1, Bathymetry. Particles are free to move horizontally and vertically within this grid's domain, independently of the grid, except for movement past the grid boundaries representing the seafloor (as defined by the bathymetry) and any shorelines.

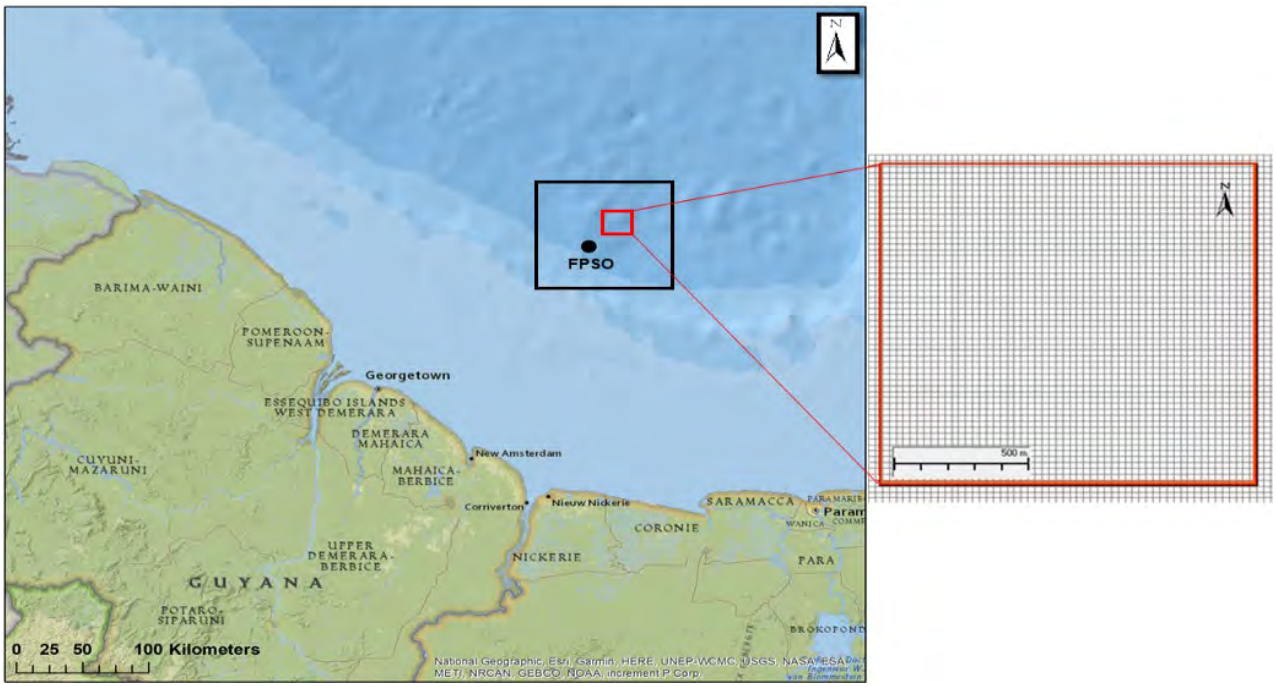
Figure 2-2: Particle Grid



For computation of the deposition on the seafloor, the model used a smaller, more finely spaced two-dimensional (2-D) depositional grid, with each grid centered on a drill center. The depositional grid is a square approximately 20 kilometers (12.4 miles) on each side. Cell sizes vary in size from 10 meters (32.8 feet) by 10 meters (32.8 feet) near the center to 100 meters (328 feet) by 100 meters (328 feet) at the edge of the grid. Figure 2-3 shows a closer look at the depositional grid in the vicinity of the FPSO.

The concentration grid, used for computation of TSS concentrations in the water column, is 3-D, with the same horizontal dimensions as the depositional grid. Vertically, the cells are 10 meters (32.8 feet) thick at the surface and bottom of the water column, where the maximum TSS concentrations are predicted to occur. The cell thicknesses expand in size toward the middle of the water column.

Figure 2-3: Depositional and Concentration Grid



m = meter

A summary of the dimensions of these grids is presented in Table 2-7.

Table 2-7: Grid Dimensions

Grid	Horizontal Dimensions (meters)	Vertical Dimensions
Particle grid	50 x 50	NA
Depositional grid	Variable—smallest 10 x 10 at center	NA
Concentration grid	Variable—smallest 10 x 10 at center	Variable—smallest 5 meters at top and bottom of water column

NA = not applicable

2.1.2 Drill Cuttings and Mud Deposition Software

The modeling was performed using the software package Generalized Environmental Modelling System for Surfacewaters (GEMSS®) and its drill cuttings and muds discharge module, Generalized Integrated Fate and Transport (GIFT) (Kolluru and Spaulding 1993; Kolluru, et al. 1998; Fichera and Kolluru 2007; Fichera et al. 2013; Prakash and Kolluru 2014). GIFT can simulate the fate of dissolved and particulate material discharged from a range of sources, including drill cuttings and muds and produced water. This 3-D particle-based model uses Lagrangian algorithms in conjunction with currents, specified mass load rates, release times and locations, particle sizes, settling velocities, and shear stress values. The modeling methodology is based on a deterministic mode of simulation. In deterministic, single-event simulations, the starting date and current speed and direction at each time step are chosen from a database of properties in the selected periods.

Drill cuttings and muds were modeled as particles. Movement in the vertical direction resulted in the settling and deposition of cuttings on the seabed. The deposition, based on particle size distribution and the intensity of release, results in the predicted accumulation of drill cuttings on the seabed.

Modeling data inputs included:

- Drill section sizes and schedule;
- Drilling mud types;
- Cuttings and mud grain size distribution;
- Mud and cuttings densities; and
- Mud and cuttings release rates, durations, and discharge depths.

2.1.3 Environmental Data

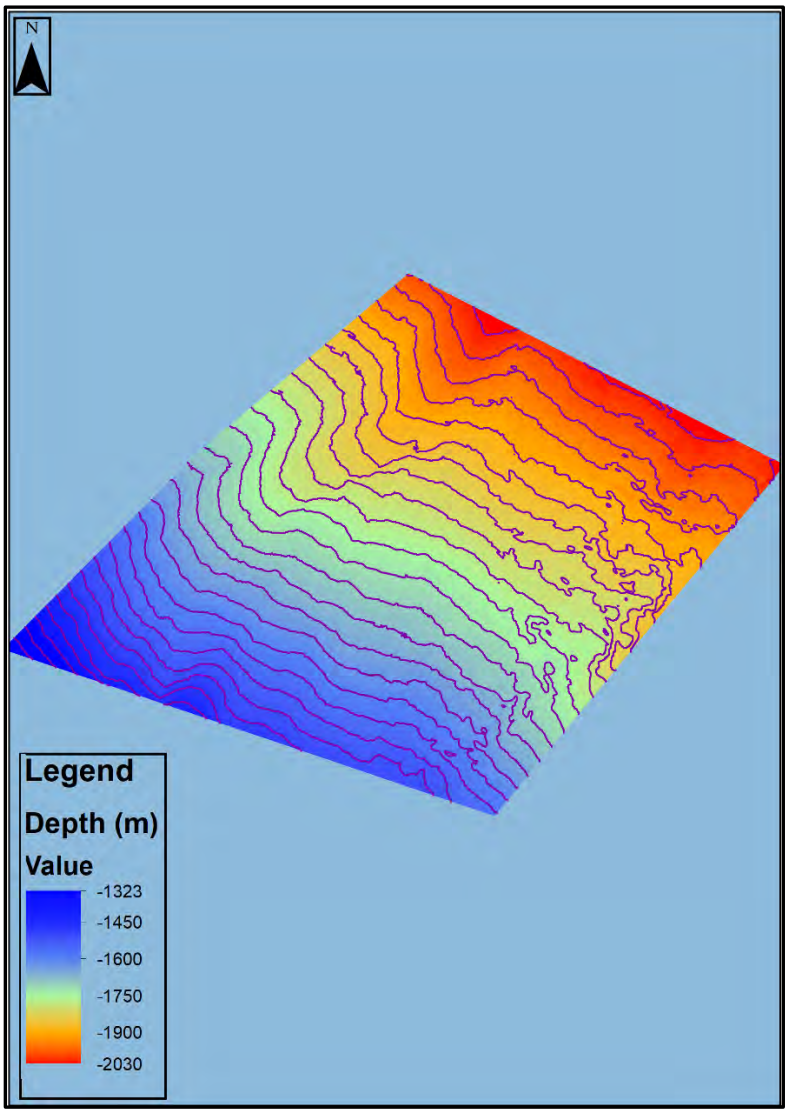
Model inputs were assembled and formatted for use with GIFT. The environmental data used by the model included bathymetry, ocean current, water temperature, and salinity data. Spatially and temporally varying oceanic data were collected to characterize the area in which the discharges will occur and to determine appropriate simulation periods to represent the range of potential results (see Yellowtail EIA Section 6.4.2, Existing Conditions—Marine Water Quality).

2.1.3.1 Bathymetry

The primary spatial dataset is bathymetric data, used to describe the depth and shape of the seafloor. Bathymetric data are used to develop the lower boundary of the modeling grids. EEPGL supplied bathymetry contour data at the study site with contour intervals of 25 meters (82 feet). The bathymetric contours are shown on Figure 2-4.

A polyline shapefile of the Guyana coastline was used as a boundary in the model domain between land and water. The coastline boundary was obtained from Esri's World Boundaries and Places Alternate product.

Figure 2-4: EEPGL Bathymetry Data Offshore Guyana



m = meters

2.1.3.2 Time Varying Data: Ocean Current, Temperature, and Salinity Data

The time-varying data used for the drill cuttings deposition modeling included ocean current speed and direction, water temperature, and salinity. Deposition modeling requires time-varying currents on a 3-D grid. Hourly depth-varying and spatially varying currents were obtained from ExxonMobil Upstream Research Company using the SAT-OCEAN model combined with currents from the HYbrid Coordinate Ocean Model (HYCOM) global ocean circulation hindcast model. Currents were obtained every 3 hours from 2005 through 2014. The model extended from 56ºW to 58ºW longitude and 7ºN to 11ºN latitude over 128 by 128 grid cells and 22 depth bins at 0-, 5-, 10-, 20-, 30-, 40-, 50-, 75-, 100-, 125-, 150-, 200-, 300-, 400-, 500-, 1,000-, 1,500-, 2,000-, 2,500-, 3,000-, 3,500-, and 4,000-meter (0-, 16.4-, 32.8-, 65.6-, 98.4-, 131.2-, 164-, 246.1-, 328.1-, 410.1-, 492.1-, 656.2-, 984.3-, 1,312.3-, 1,640.4-, 3,280.8-, 4,921.3-, 6,561.7-, 8,202.1-, 9,842.5-, 11,482.9-, and 13,123.4-foot) depths. Depth-varying temperature and salinity values were obtained directly from HYCOM model output.

Monthly averaged, depth-averaged current speeds were computed across the 2005 to 2014 period of record. Through a statistical analysis of these current speeds at the well locations, the months with the minimum and maximum average current speeds were determined. Modeling was performed assuming drill cuttings deposition occurs starting on the first day of these 2 months: March 2006 (maximum speed) and August 2013 (minimum speed). Simulations performed during these 2 months will provide the extremes of the full range of depositional patterns (i.e., from a larger and thinner footprint when the current speeds are highest to a smaller and thicker footprint when the current speeds are lowest).

Example current vector plots for March 2006 and August 2013 are shown below on Figure 2-5 and Figure 2-7 (showing current speeds and directions at the sea surface) and on Figure 2-6 and Figure 2-8 (showing current speeds and directions at a depth of 1,000 meters [3,280.8 feet]).

2.1.3.3 Drill Cuttings and Mud Volumes and Properties

Estimated quantities of drill cuttings and fluids to be discharged during drilling are provided for locations DC1-I and DC3-P in Table 2-8 and Table 2-9, respectively. The estimated times to drill each section were provided by EEPGL (as discussed above). For the top-hole sections (Sections 1 and 2), only WBM is expected to be used and cuttings will be discharged at the seafloor. For Sections 3 through 5, the cuttings with a small percentage of adhered non-aqueous muds will be discharged at a depth of 11 meters (36.1 feet) below sea level. No non-aqueous drilling muds will be directly discharged. Solids control and cuttings drying equipment will be installed on the drill ships to process and reduce the percentage of NADF retained on cuttings, such that non-aqueous base fluid (NABF) retained on discharged cuttings will not exceed 6.9 percent (by mass) on average. Accordingly, the modeling assumed an NABF content of 6.9 percent by mass for all discharged cuttings.

Table 2-8: Discharge Description for Location DC1-I

Hole Diameter, millimeters (inches)	Volume of Cuttings to be Discharged, bbl (m^3)	Volume of Drilling Fluid to be Discharged, bbl (m^3)	Type of Drilling Fluid	Modeled Cuttings Discharge Duration (days)
914.4 (36)	545.32 (87.3)	683.96 (109.4)	WBM	0.5

2.1.3.4 Cuttings and Mud Properties

The grain size properties of the drill cuttings and muds were provided by EEPGL. The distribution of particle sizes and associated fall velocities used in this study are listed in Table 2-10 for cuttings discharged from Section 1 and 2, in Table 2-11 for WBM, and in Table 2-12 for treated cuttings with NADF discharged from Sections 3 through 5. Cuttings density was assumed to be 2.6 kilograms per liter. The WBM density was assumed to be 11 pounds per gallon (ppg) (1.3 kilograms per liter [kg/L]). The density of NADF was reported by EEPGL to range between 9 and 13.2 ppg (1.1 to 1.6 kg/L); 9 ppg (1.1 kg/L) was used as a conservative assumption since it would result in slower settling and a larger footprint of deposition.

Table 2-10: Properties of Cuttings for Well Sections 1 and 2 (Water-Based Fluid)

Estimated Diameter (cm)	Mass Fraction (wt%)	Fall Velocity (cm/s)
0.00005	2	0.00003
0.0001	3	0.0001

[a] Fall velocity outside the range of available correlations; size computed internally by GIFT model. Fall velocities were based on experiments. These velocities were directly used in the GIFT model to estimate settlement. Estimated diameter sizes are only for reference and do not affect GIFT computations.

2.2 Simulations

Modeling was performed for 12 simulations: for each of three scenarios at each of the two modeled locations (DC1-I and DC3-P), at each of the minimum and maximum ambient current scenarios determined by the monthly averaged, depth-averaged currents analysis (see Table 2-13).

Table 2-13: Drill Cuttings and Fluid Deposition Simulations

Drill Center	Scenario	Parameter(s) Evaluated	Ambient Current Scenario
DC1-I	1	Depositional Thickness Bottom TSS	Minimum Monthly Average
			Maximum Monthly Average
	2	Depositional Thickness Bottom TSS Surface TSS	Minimum Monthly Average
			Maximum Monthly Average
	3	Hydrocarbon Mass Deposition	Minimum Monthly Average
			Maximum Monthly Average
DC3-P	1	Depositional Thickness Bottom TSS	Minimum Monthly Average
			Maximum Monthly Average
	2	Depositional Thickness Bottom TSS Surface TSS	Minimum Monthly Average
			Maximum Monthly Average
	3	Hydrocarbon Mass Deposition	Minimum Monthly Average
			Maximum Monthly Average

Because Scenario 1 results in only bottom discharges from the sequential jetting/drilling of the top-hole sections of four wells, the simulations include predicted cuttings depositional thickness on the seabed on a 2-D basis and TSS concentrations in the water column on a 3-D basis. Scenario 2 drilling results in both bottom and surface discharges. Consequently, depositional thickness as well as surface and bottom TSS concentrations were evaluated. Scenario 3 evaluated the sequential drilling of bottom holes (Sections 3 through 5) for four wells, which represents the worst case for hydrocarbon deposition (from the perspective of temporal overlap) resulting from surface discharges of treated drill cuttings. For this scenario, the mass of deposited hydrocarbons on a 2-D basis was evaluated.

2.2.1 Cuttings Depositional Thickness

Burial by drilling mud and cuttings may cause physical impacts on benthic communities on the seabed. The potential severity of burial impacts depends on the sensitivity of the benthic organism, the thickness of deposition, the amount of oxygen-depleting material, and the duration of the burial. Thickness thresholds vary by species and sediment impermeability. A suggested threshold deposition rate of 5 centimeters (2 inches) per month is recommended based on Ellis and Heim (1985) and MarLIN (2019). Smaller threshold values as low as 1 millimeter (0.04 inch) have been reported (e.g., Smit et al. 2006); however, they are associated with instantaneous burials on benthic species, not gradual smothering effects. Accordingly, for the purpose of modeling, results are presented in terms of the lateral extent of deposition exceeding 5 centimeters (2 inches) in thickness over a 30-day period. Simulations were designed with consideration to the temporal aspect of the threshold.

2.2.2 Total Suspended Solids

Increases in TSS concentrations in the water column will occur due to discharges of drill cuttings and mud. The highest concentration increases will occur at the point of discharge (i.e., at the seafloor for top sections of the well and near the sea surface for subsequent sections of the well), and will decrease over time and distance as the TSS plume dissipates and settles. Larger particles will settle out more quickly than finer particles, such that smaller particles may stay suspended longer and travel laterally further than larger particles. As such, elevated TSS concentrations may form in regions where tiny suspended particles linger in a cloud and mix with particles from subsequent discharges.

Impacts on marine organisms related to elevated TSS may occur if light penetration in the photic zone (typically the top 200 meters [656.2 feet]) is impeded significantly for long periods of time (reducing the ability of plants and phytoplankton to photosynthesize). Increases in TSS may also decrease water clarity and clog fish gills. A commonly used guidance value for TSS from effluent discharges in the marine environment recommended by MARPOL 73/78[1] is 35 milligrams per liter (mg/L) (IMO 2006). Accordingly, for the purpose of modeling, results are presented in terms of the lateral area with TSS concentrations exceeding 35 mg/L. The likelihood of impacts related to elevated TSS concentrations will tend to decrease in deeper waters below the photic zone, where photosynthesis does not occur. However, elevated TSS concentrations at deeper depths can still impact fish gills. In the absence of a depth-varying guidance value, the same value is applied throughout the water column, but delineation of potential impacts related to elevated TSS concentrations at water depths below the photic zone should be considered a more conservative estimate than near the surface.

2.3 Mass of Oil Deposition

Cuttings containing NADF will be treated through the drilling rig onboard systems (shakers and dryers). The NABF portion of the NADF that remains will be reduced to no more than 6.9 percent base fluid retention on cuttings (average, by mass). These base oils made of hydrocarbons, once settled to the

[1] International Convention for the Prevention of Pollution by Ships, 1973, as modified by the Protocol of 1978

seafloor, degrade over time, and may enter the pore water within the sediments or become dissolved in the water column, depending on each specific hydrocarbon's tendency to remain partitioned to the solids.

2.4 Results

The results of the modeling are illustrated in the following sections as contour plots. The plots presented indicate the location of the drill cuttings release point. Results are presented for each of the following parameters for the appropriate scenarios:

- Cuttings deposition thickness on the seafloor at the end of the simulation;
- Maximum TSS concentration in the water column at any time in the simulation (at the surface and at the bottom, representing the surface and seabed discharges, respectively); and
- Mass of hydrocarbons per unit area deposited on the seafloor.

As discussed above, the following threshold criteria were applied for the purpose of reporting results:

- Criterion 1—Cuttings deposition rate less than 5 centimeters (2 inches) per month; and
- Criterion 2—Recommended TSS concentrations no greater than 35 mg/L.

There are no available criteria applicable for the mass of hydrocarbons deposited on the seafloor.

2.4.1 Cuttings Depositional Thickness

2.4.1.1 Scenario 1

When the first two (top-hole) sections of a well are jetted and drilled (prior to the installation of a riser), cuttings and WBMs are discharged directly to the seabed, resulting in a mound of material deposited closely around the well. The material discharged at the seabed is mostly deposited in the area directly adjacent to each wellhead.

Figure 2-9 through Figure 2-12 present the depositional thickness for Scenario 1 for drill centers DC1-I and DC3-P. Higher thicknesses are concentrated around the drill center at the well clusters, but some discrete patches of depositional thicknesses greater than 1 millimeter (0.04 inch) are also present at some distance from these wells.

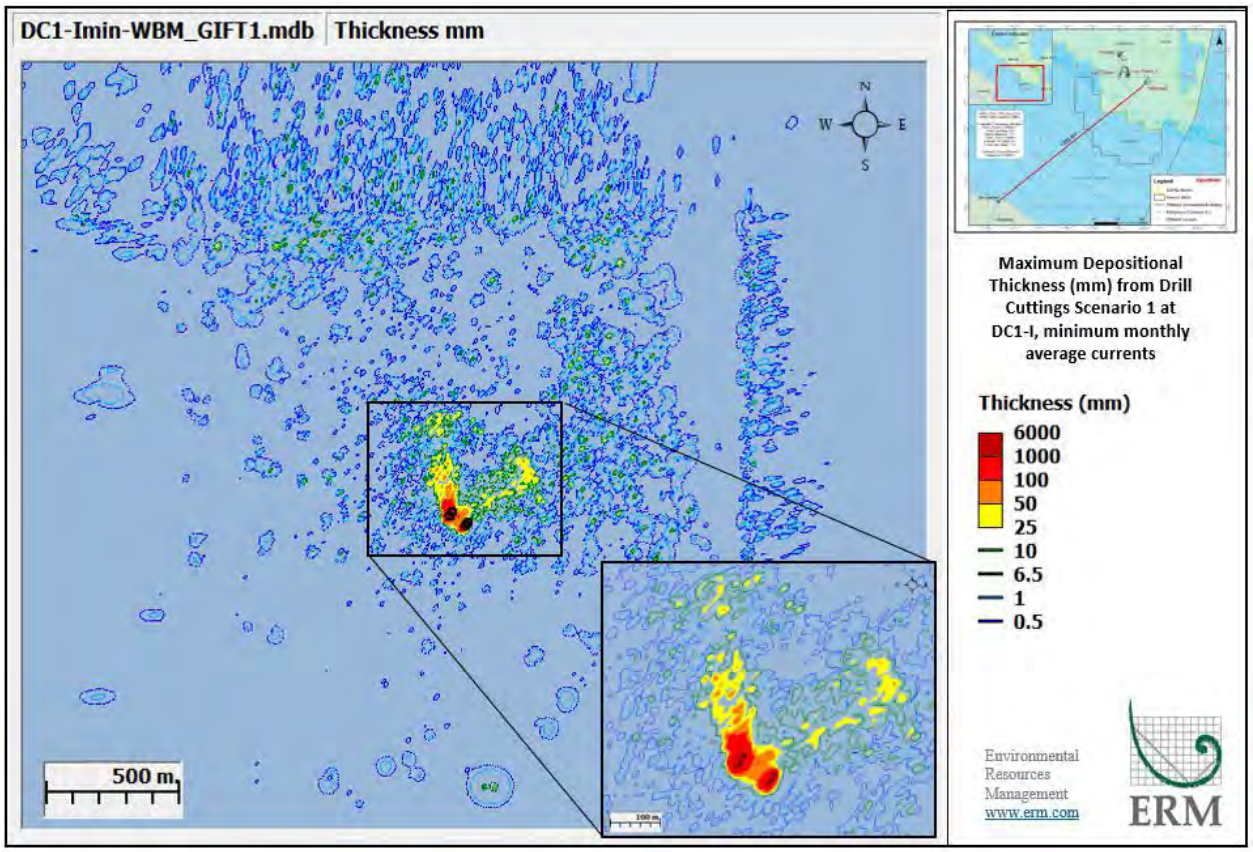
In all simulations, a small region surrounding the well clusters at the drill centers exceeds the depositional thickness threshold value of 5 centimeters (2 inches). For DC3-P, there are two deposition mounds with an approximate lateral extent of 50 meters (164 feet) where the thicknesses exceed this threshold. For DC1-I, the thicknesses exceed this threshold primarily within a 0.4-kilometer (0.23-mile) radius of the drill center. The maximum depositional thicknesses and areas exceeding the threshold value of 5 centimeters (2 inches) for Scenario 1 are presented in Table 2-14. For drill center DC1-I, the maximum depositional thickness is approximately 561 centimeters (220.9 inches) under the minimum currents simulation. For drill center DC3-P, the maximum depositional thickness is approximately 200 centimeters (78.7 inches) under the maximum currents simulation. It is noted that these are conservatively high estimates, as slope failures (i.e., collapse of the depositional mound) and resuspension of the particles by ocean currents are likely to reduce the height of the deposited materials over time.

Table 2-14: Summary of Results—Cuttings Depositional Thickness: Scenario 1

Simulation	Maximum Depositional Thickness (cm)	Area (m^2) with Thickness > 5 cm threshold
DC1-I Scenario 1 Minimum Currents	560.8	8,381
DC1-I Scenario 1 Maximum Currents	443.1	7,234
DC3-P Scenario 1 Minimum Currents	190.3	3,969
DC3-P Scenario 1 Maximum Currents	200.2	3,436

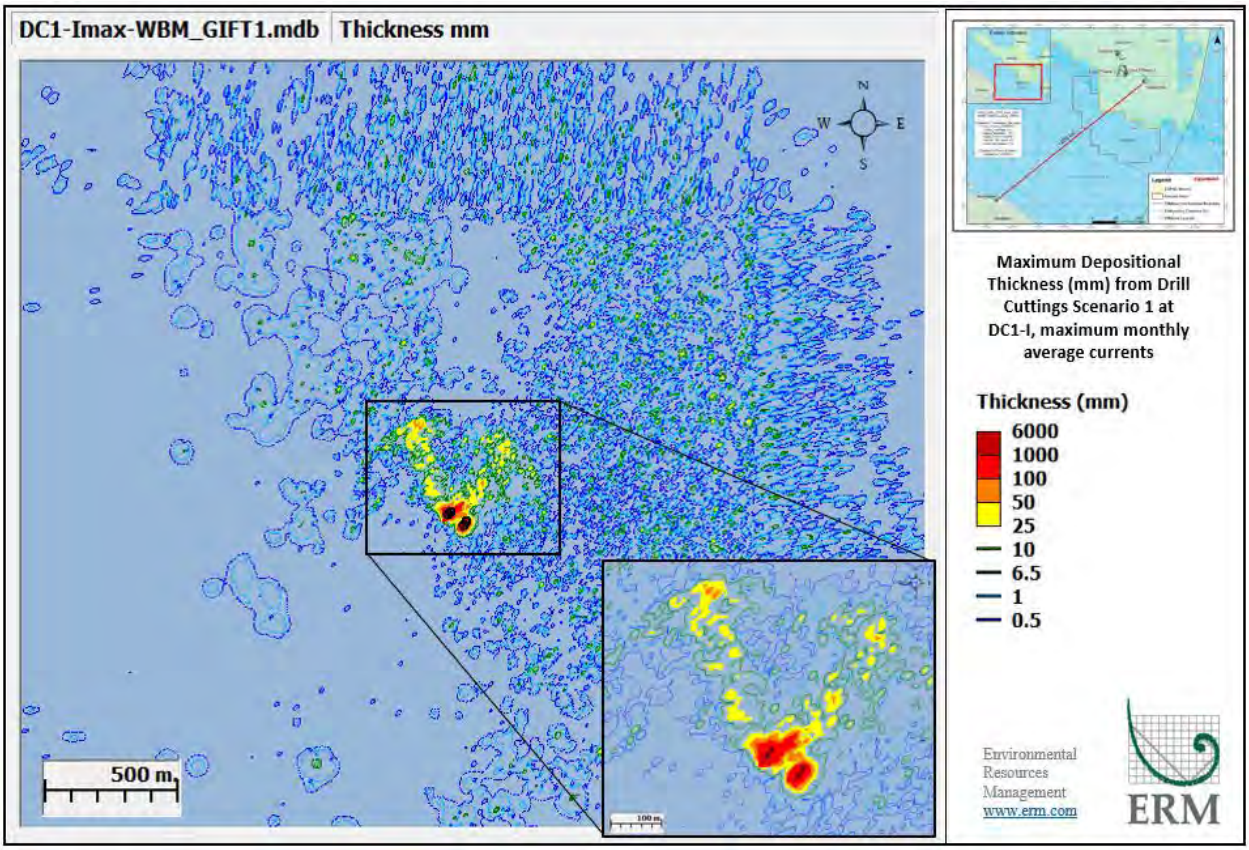
cm = centimeter; m^2 = square meter

Figure 2-9: Maximum Depositional Thickness—Scenario 1 DC1-I: Minimum Currents



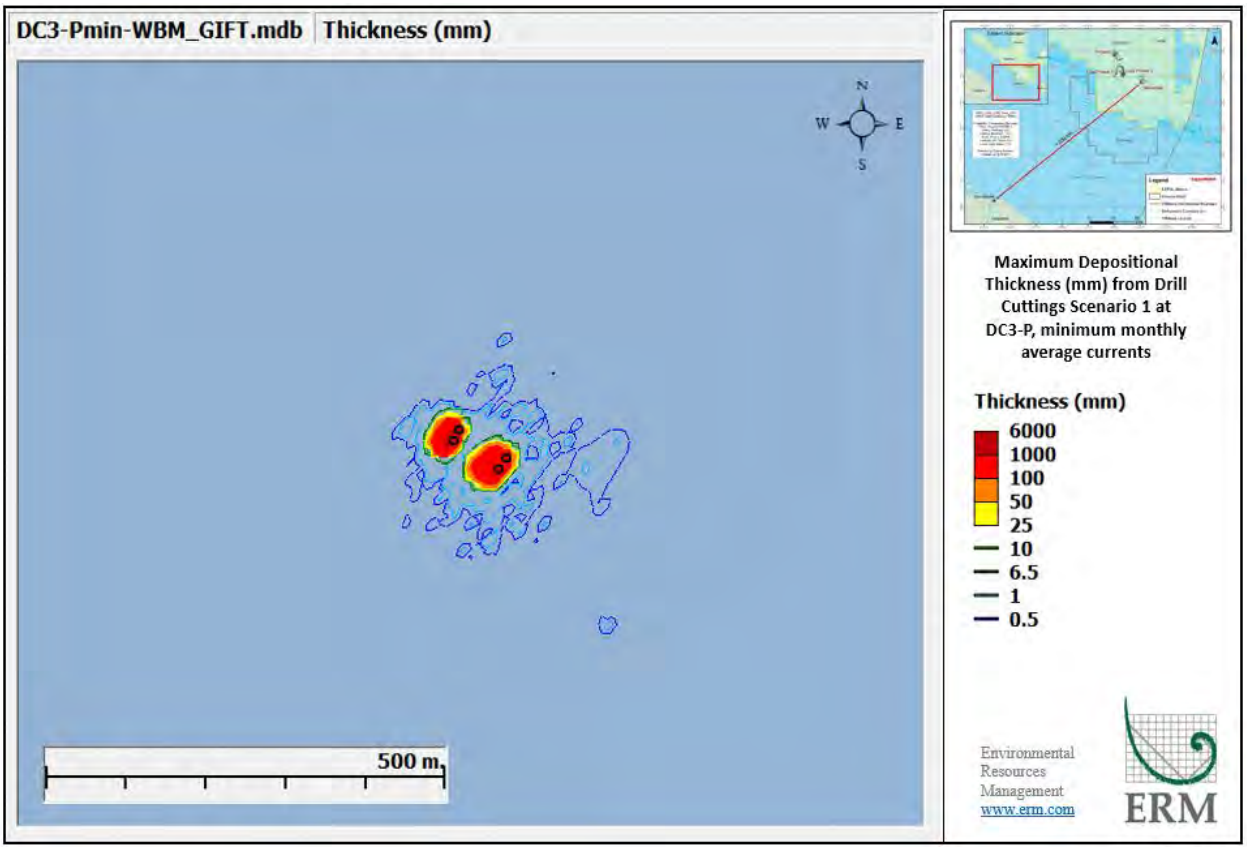
m = meter; mm = millimeter

Figure 2-10: Maximum Depositional Thickness—Scenario 1 DC1-I: Maximum Currents



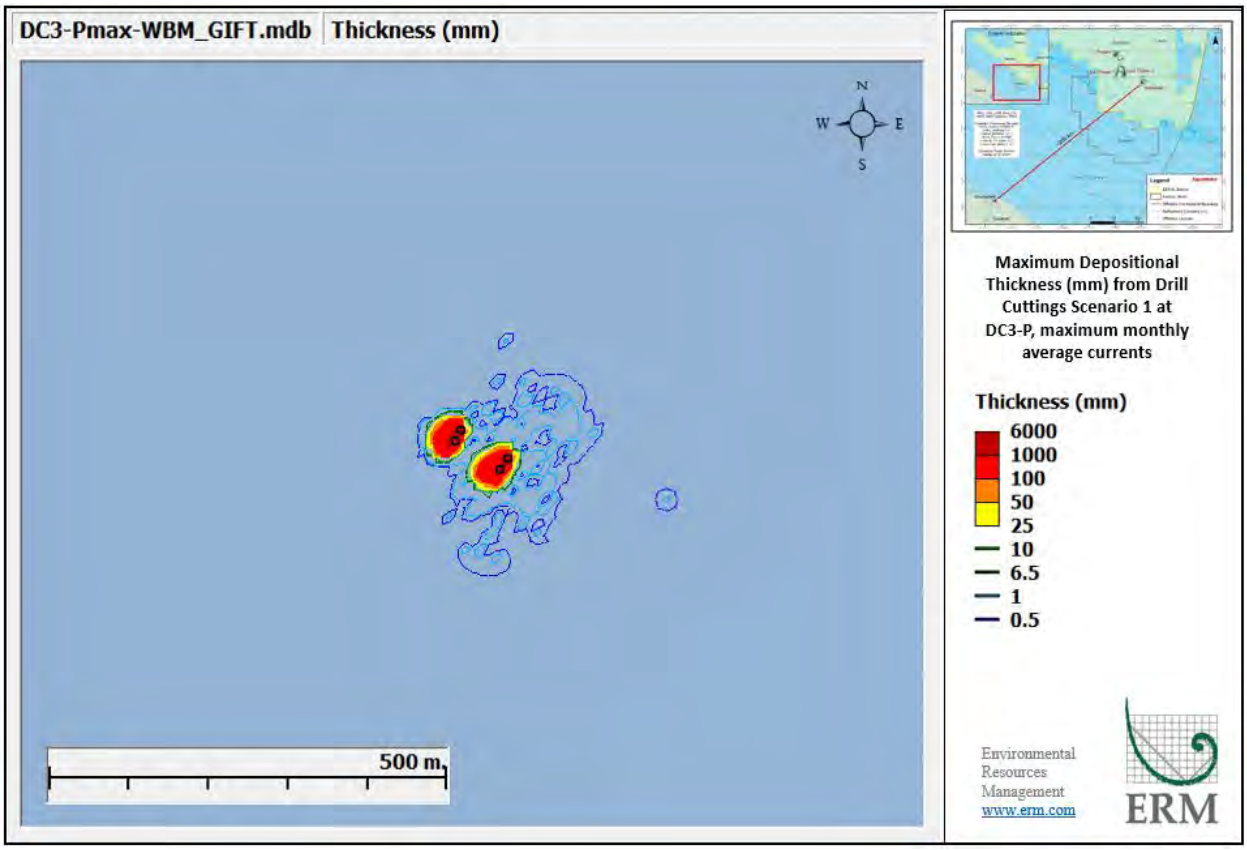
m = meter; mm = millimeter

Figure 2-11: Maximum Depositional Thickness—Scenario 1 DC3-P: Minimum Currents



m = meter; mm = millimeter

Figure 2-12: Maximum Depositional Thickness—Scenario 1 DC3-P: Maximum Currents



m = meter; mm = millimeter

2.4.1.2 Scenario 2

Figure 2-13 through Figure 2-16 present the depositional thickness for Scenario 2 for drill centers DC1-I and DC3-P. For both DC1-I and DC3-P, higher thicknesses are concentrated around the well cluster associated with the drill center, but discrete patches of depositional thicknesses greater than 1 millimeter (0.04 inch) thickness are also present. In all simulations, a small region close to the drill centers exceeds the depositional thickness threshold value of 5 centimeters (2 inches). There is one deposition mound with an approximate lateral extent of 50 meters (164 feet) where the thicknesses exceed this threshold.

The maximum depositional thicknesses and areas exceeding the threshold value of 5 centimeters (2 inches) for Scenario 2 are presented in Table 2-15. For drill center DC1-I, the maximum depositional thickness is approximately 258 centimeters (101.6 inches) under the maximum current simulation. For drill center DC3-P, the maximum depositional thickness is approximately 170 centimeters (70 inches) under the maximum current simulation. It is noted that these are conservatively high estimates, as slope failures (i.e., collapse of the depositional mound) and resuspension of the particles by ocean currents are likely to reduce the height of the deposited materials over time.

Table 2-15: Summary of Results—Cuttings Depositional Thickness: Scenario 2

Simulation	Maximum Depositional Thickness (cm)	Area (m^2) with Thickness > 5 cm threshold
DC1-I Scenario 2 Minimum Currents	247.1	1,632
DC1-I Scenario 2 Maximum Currents	258.4	1,939
DC3-P Scenario 2 Minimum Currents	126.7	2,135

2.4.2 Total Suspended Solids

2.4.2.1 Scenario 1

Figure 2-17 through Figure 2-20 present the predicted TSS concentrations added above ambient levels at the time when the maximum Project-generated area exceeding the above-referenced TSS concentration guideline value[2] occurs near the seabed. A separate “maximum” event was captured for near-seabed concentrations (correlating with direct discharge at the seabed).

Table 2-16 summarizes the maximum predicted surface and bottom TSS concentrations modeled and the maximum areas with TSS concentrations exceeding the 35 mg/L threshold under minimum and maximum current conditions at each drill center.

[2] As noted above, the likelihood of impacts related to elevated TSS concentrations will tend to decrease in deeper waters below the photic zone, where photosynthesis does not occur. However, elevated TSS concentrations at deeper depths can still impact fish gills. In the absence of a depth-varying guidance value, the same value is applied in the EIA throughout the water column, but delineation of potential impacts related to elevated TSS concentrations at water depths below the photic zone (as in the case of Scenario 1) should be considered a conservative estimate of potential impact.

Table 2-16: Total Suspended Solids Summary—Scenario 1

Simulation	Maximum TSS (mg/L)		Maximum Area (m^2) with TSS >35 mg/L Threshold	
	Surface	Bottom	Surface	Bottom
Scenario 1: DC1-I Minimum Currents	NA	52,248	NA	400,000
Scenario 1: DC1-I Maximum Currents	NA	43,854	NA	991,000
Scenario 1: DC3-P Minimum Currents	NA	55,939	NA	81,100
Scenario 1: DC3-P Maximum Currents	NA	33,152	NA	60,800

km^2 = square kilometer; NA = not applicable

At the DC1-I drill center, the maximum TSS concentration added above ambient as a result of seabed discharges ranged from 43,854 mg/L under maximum monthly averaged currents to 52,248 mg/L under minimum monthly averaged currents. The maximum area with TSS exceeding the 35 mg/L threshold was 400,000 square meters (m^2) (0.2 square mile [mi^2]) under minimum currents and 991,000 m^2 (0.4 mi^2) under maximum currents.

At the DC3-P drill center, the maximum TSS concentration added above ambient as a result of seabed discharges ranged from 33,152 mg/L under maximum currents to 55,939 mg/L under minimum currents. The maximum area with TSS exceeding the 35 mg/L threshold was 81,100 m^2 (0.03 mi^2) under minimum currents and 60,800 m^2 (0.02 mi^2) under maximum currents.

Figure 2-17: Maximum Area of TSS Exceedance near the Bottom—Scenario 1 DC1-I: Minimum Currents

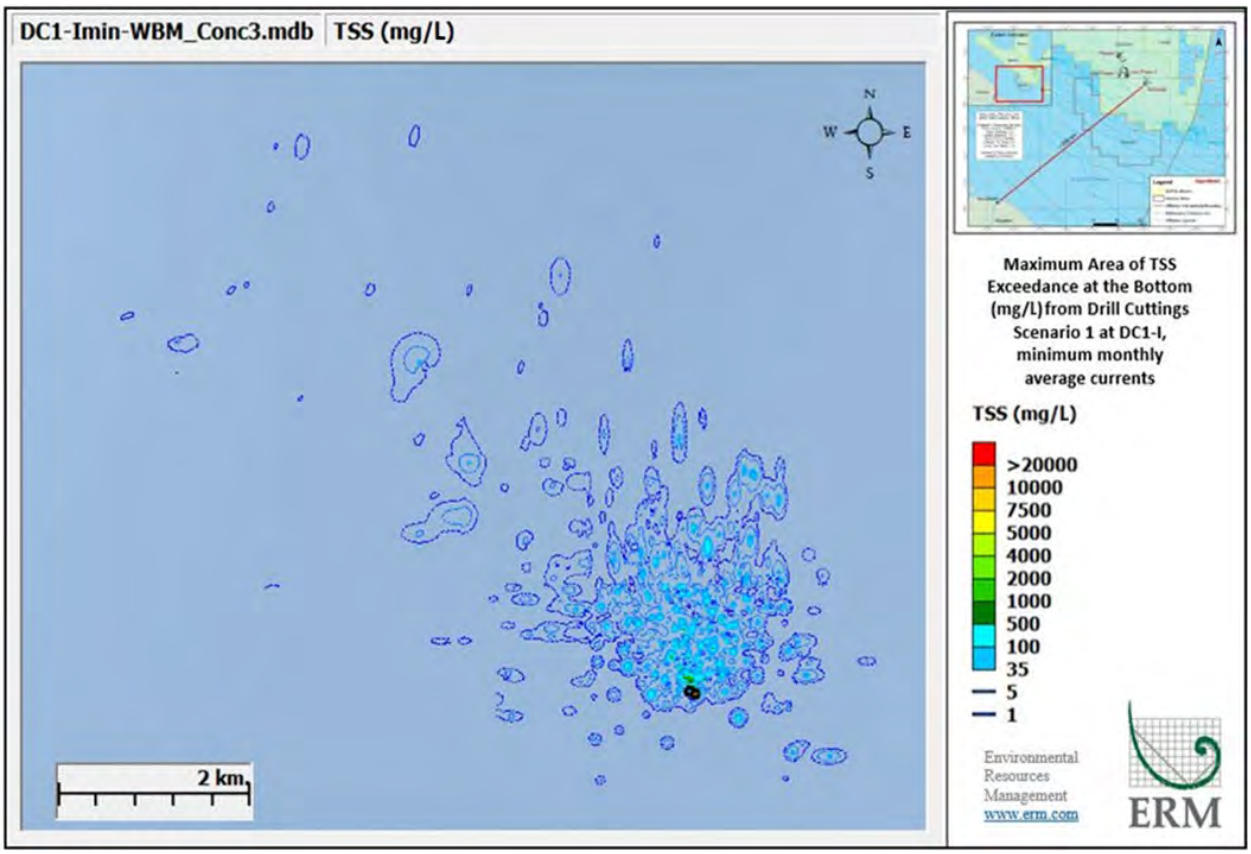

Figure 2-18: Maximum Area of TSS Exceedance near the Bottom—Scenario 1 DC1-I: Maximum Currents

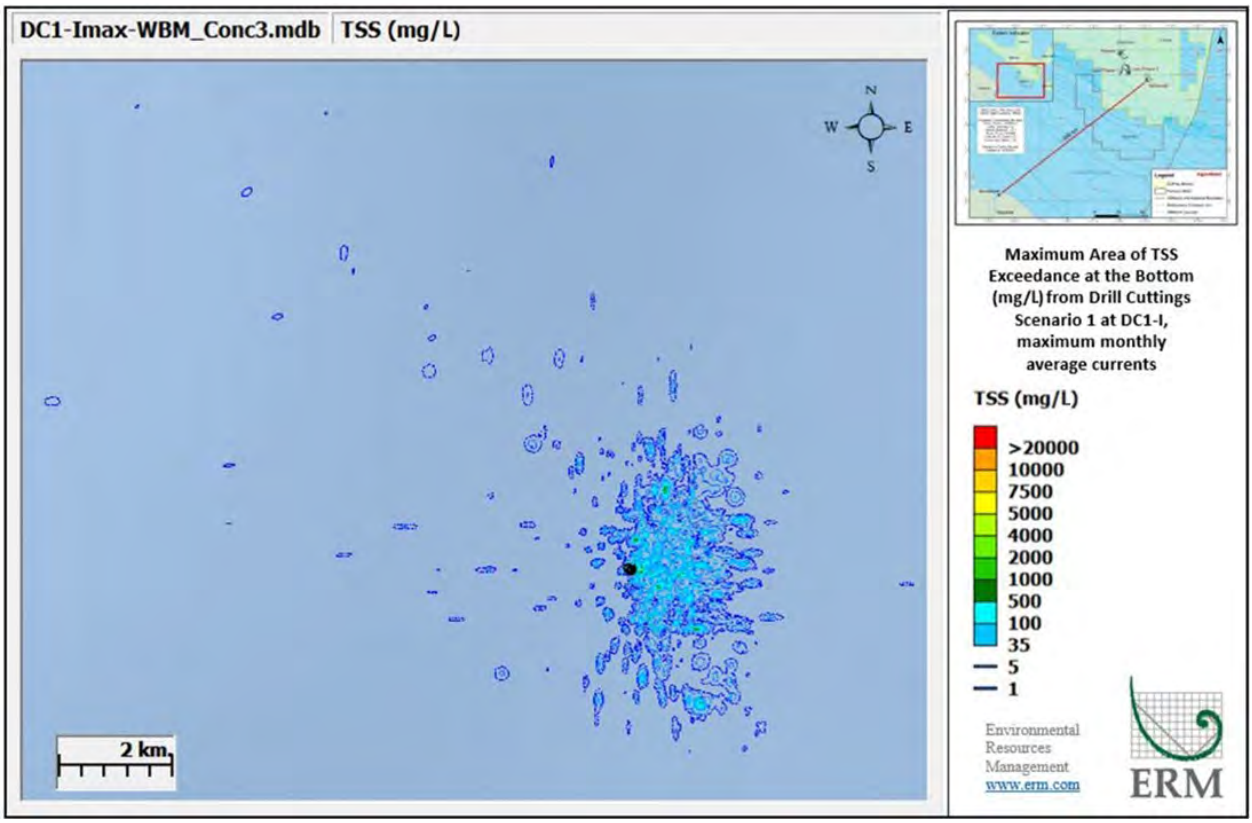

Figure 2-19: Maximum Area of TSS Exceedance near the Bottom—Scenario 1 DC3-P: Minimum Currents

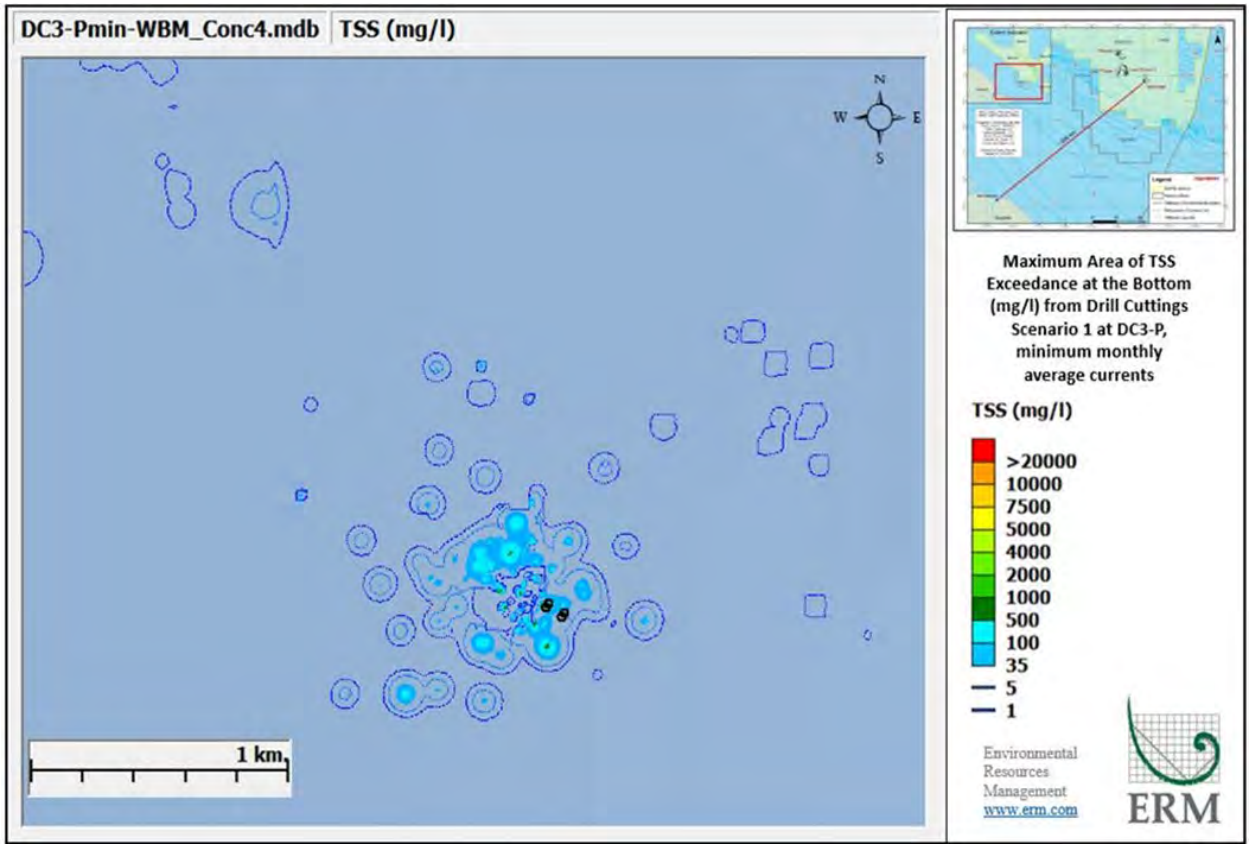

Figure 2-20: Maximum Area of TSS Exceedance near the Bottom—Scenario 1 DC3-P: Maximum Currents

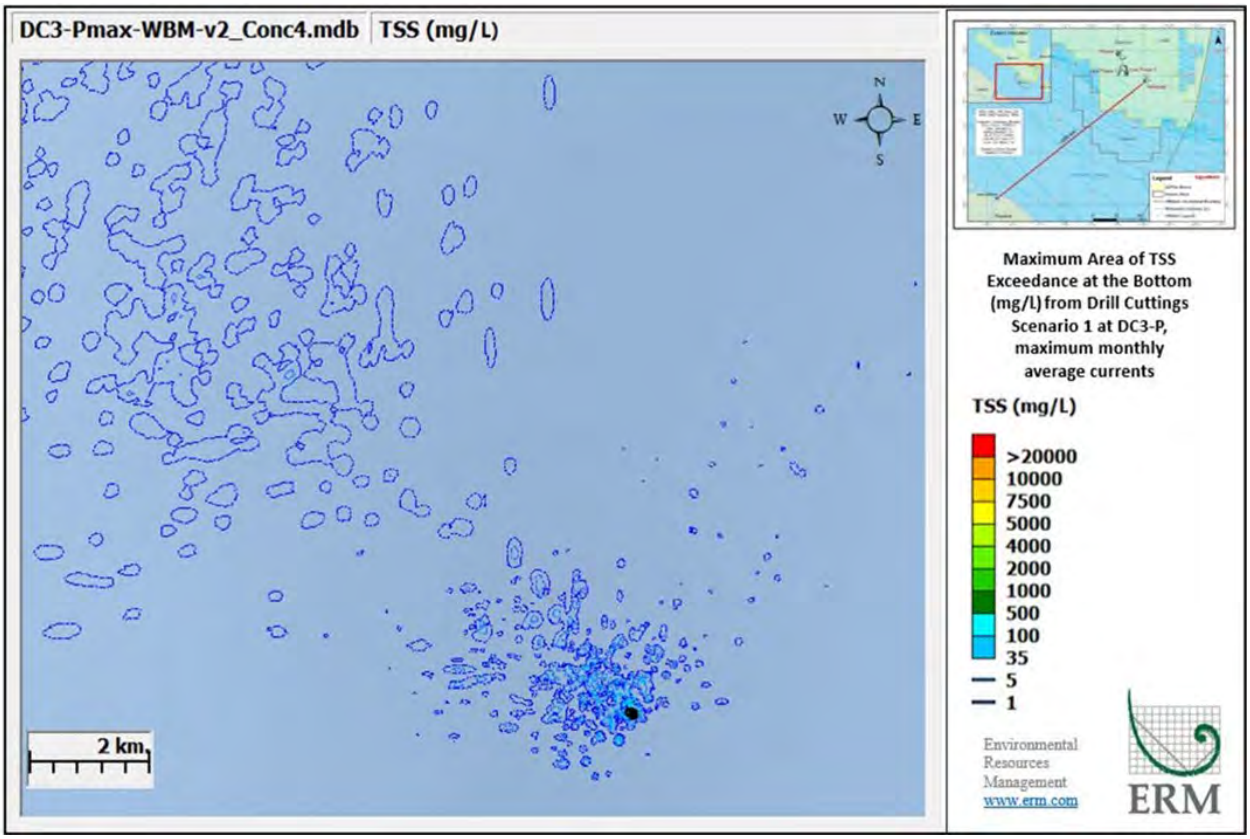

2.4.2.2 Scenario 2

Figure 2-21 through Figure 2-24 present the predicted TSS concentrations added above ambient levels at the time when the maximum Project-generated area of TSS exceedance occurs near the seabed. Figure 2-25 through Figure 2-28 present the predicted TSS concentrations added above ambient levels at the time when the maximum Project-generated area of TSS exceedance occurs from surface discharges, when applicable.

At the DC1-I drill center, the maximum instantaneous TSS concentration added above ambient as a result of seabed discharges ranges from 18,717 mg/L under minimum currents to 33,323 mg/L under maximum monthly averaged currents. The maximum area with TSS exceeding the 35 mg/L threshold is 366,000 m^2 (0.1 mi^2) under maximum currents and 240,000 m^2 (0.1 mi^2) under minimum currents. For surface discharges, the maximum instantaneous TSS concentration added above ambient ranges from 87.7 mg/L under maximum currents to 951.9 mg/L under minimum currents. The maximum area of TSS exceeding the 35 mg/L threshold is 23,200 m^2 (0.009 mi^2) under maximum currents and 12,000 m^2 (0.005 mi^2) under the minimum currents.

At the DC3-P drill center, the maximum instantaneous TSS concentration added above ambient as a result of seabed discharges ranges from 8,412 mg/L under maximum currents to 14,711 mg/L under minimum currents. The maximum area with TSS exceeding the 35 mg/L threshold is 187,000 m^2 (0.1 mi^2) under maximum currents and 207,000 m^2 (0.1 mi^2) under minimum currents. For surface discharges, the maximum instantaneous TSS concentration added above ambient ranges from 21.3 mg/L under maximum currents to 1,013 mg/L under minimum currents. The maximum area of TSS exceeding the

35 mg/L threshold is 13,400 m^2 (0.005 mi^2) under minimum currents. The threshold is not exceeded under maximum currents.

Note that on the following figures, the estimated maximum instantaneous TSS concentrations may be slightly offset from the discharge location as the simulation's floating small particles suspended in the water column may concentrate together at various locations. Larger particles do not remain suspended but quickly settle to the seafloor.

Table 2-17 summarizes the maximum instantaneous predicted surface and bottom TSS concentrations modeled and the lateral areas with TSS concentrations exceeding the 35 mg/L threshold under minimum and maximum current conditions at each drill center.

Table 2-17: Total Suspended Solids Summary—Scenario 2

Simulation	Maximum TSS (mg/L)		Area (m^2) with TSS >35 mg/L Threshold	
	Surface	Bottom	Surface	Bottom
Scenario 2: DC1-I Minimum Currents	951.9	18,717	12,000	240,000
Scenario 2: DC1-I Maximum Currents	87.7	33,323	23,200	366,000
Scenario 2: DC3-P Minimum Currents	1,013	14,711	13,400	207,000

2.4.3 Mass of Oil Deposited on the Seabed

Figure 2-29 through Figure 2-32 present the predicted hydrocarbon deposition on the seabed based on the statistical summary identifying the maximum hydrocarbon deposition occurring on the ocean floor during the entire simulation period. At the end of the simulation period (87 days), NABF adhered to the cuttings settles primarily within an approximately 2.5-kilometer (1.6-mile) radius of the drill center for all four simulations.

For drill center DC1-I, the maximum hydrocarbon deposition under the minimum monthly averaged current scenario is 256.9 grams per square meter (g/m²) and is 237.2 g/m² under the maximum monthly averaged current scenario.

For drill center DC3-P, the maximum hydrocarbon deposition under the minimum monthly averaged current scenario is 200.5 g/m² and is 186.6 g/m² under the maximum monthly averaged current scenario.

[3] TSS concentrations in this scenario appear smaller than in the other scenarios. The fast currents, generally directing the particles toward the northwest, quickly spread and dilute the released mass. The square shape of the plume is a modeling artifact from depicting radially decreasing concentrations around a discrete location with high TSS.

Table 2-18: Hydrocarbon Deposition Summary

Simulation	Maximum Hydrocarbon Deposition (g/m²)
Scenario 3: DC1-I Minimum Currents	256.9
Scenario 3: DC1-I Maximum Currents	237.2
Scenario 3: DC3-P Minimum Currents	200.5
Scenario 3: DC3-P Maximum Currents	186.6

2.5 Conclusions

Drill cuttings deposition modeling was performed using GEMSS® and its drill cuttings and muds deposition module, GIFT. Twelve simulations were modeled, representing two drill centers (DC1-I and DC3-P) and three drilling scenarios under two ambient current conditions (minimum and maximum monthly averaged, depth-averaged current speeds over a 10-year period of record).

Output from the drill cutting deposition modeling included estimations of the distribution of deposited cuttings thickness on the seafloor, the maximum instantaneous increase in TSS concentrations above ambient conditions, and the distribution of mass of hydrocarbons adhered to cuttings deposited on the seafloor. The results of the modeling are shown below in Table 2-19.

Table 2-19: Model Results Summary

Simulation	Maximum Depositional Thickness (cm)	Area (m²) with Thickness >5 cm Threshold	Maximum TSS (mg/L)— Bottom/ Surface	Area (m²) with TSS >35 mg/L Threshold— Bottom/ Surface	Maximum Adhered Oil Deposition (g/m²)
Scenario 1—DC1-I Minimum Currents	560.8	8,381	52,248	400,000	NA
Scenario 1—DC1-I Maximum Currents	443.1	7,234	43,854	991,000	NA
Scenario 1—DC3-P Minimum Currents	190.3	3,969	55,939	81,100	NA
Scenario 1—DC3-P Maximum Currents	200.2	3,436	33,152	60,800	NA
Scenario 2—DC1-I Minimum Currents	247.1	1,632	18,717/ 951.9	240,000 / 12,000	NA
Scenario 2—DC1-I Maximum Currents	258.4	1,939	33,323/ 87.7	366,000 / 23,200	NA
Scenario 2—DC3-P Minimum Currents	126.7	2,135	14,711/ 1,013	207,000 / 13,400	NA
Scenario 2—DC3-P Maximum Currents	169.8	1,814	8,412/ 21.3	187,000/ 0	NA
Scenario 3—DC1-I Minimum Currents	NA	NA	NA	NA	256.9
Scenario 3—DC1-I Maximum Currents	NA	NA	NA	NA	237.2
Scenario 3—DC3-P Minimum Currents	NA	NA	NA	NA	200.5
Scenario 3—DC3-P Maximum Currents	NA	NA	NA	NA	186.6

cm = centimeter; NA = not applicable

In all simulations, a small region close to the drill centers exceeded the depositional thickness threshold value of 5 centimeters (2 inches). For DC1-I, the region of exceedance was within 370 meters (1,214 feet) of the drill center. For DC3-P, the lateral extent of the deposition mound where thicknesses exceed this threshold was approximately 50 meters (164 feet). The bulk of the depositional mound results from the cuttings and muds discharged during the jetting and drilling of the two top-hole sections. The maximum increase in TSS concentration above ambient conditions in the bottom of the water column is predicted to be as much as 55,939 mg/L at the point of release; however, these concentrations will occur at water depths below the photic zone, in areas where photosynthesis inhibition is not a concern. For minimum current conditions, the maximum instantaneous TSS concentration increases above ambient in the shallow water column is 1,013 mg/L. For maximum current conditions, the maximum instantaneous TSS concentration increases above ambient in the shallow water column is 87.7 mg/L. Hydrocarbon deposition on the seafloor had a maximum predicted value of 256.9 g/m².

Variations in the current speeds are the primary cause for the variations in the model results provided. In general, scenarios with minimum currents have higher areas of deposition greater than the 5-centimeter (2-inch) threshold and higher bottom TSS concentrations compared to the scenarios with maximum currents. Slower currents allow for a less dispersed settling and therefore a more laterally concentrated deposition and more concentrated TSS.

Similar to the depositional thickness, scenarios with minimum currents have higher hydrocarbon deposition per unit area compared to scenarios with maximum currents. Slower currents allow for a more concentrated deposition of hydrocarbon-containing cuttings.

3. OFFSHORE DISCHARGES MODELING

3.1 Approach

The Project will have several planned discharges to water associated with subsea, umbilicals, risers, and flowlines (SURF) and FPSO commissioning activities, as well as FPSO production operations. These discharges, based on the preliminary Project design information, are listed in Table 3-1.

Table 3-1: Summary of Planned Commissioning- and Production-Related Discharges

Type of Discharge and Estimated Effluent Characteristics [a]	Estimated Discharge Volume/Rate [a]
Ballast Water (FPSO initial deballasting)	≤550,000 bbl (≤ 87,500 m^3) total
Hydrostatic Test Water ■ Biocide / oxygen scavenger / corrosion inhibitor: 1,500 ppm	65,000 bbl (10,400 m^3) (total volume for all flowlines and risers, occurring throughout SURF commissioning phase)
Gas Re-injection Line Commissioning Fluids ■ Hydrate inhibitor (e.g., methanol or ethylene glycol)	1,400 bbl (223 m^3) total
Produced Water ■ Oil and grease ■ Temperature (55°C/131°F at point of discharge) ■ Residual production and water treatment chemicals – Scale Inhibitor ≤100 ppm – Corrosion Inhibitor ≤200 ppm ■ Hydrate inhibitor (e.g., methanol) [b]	≤300,000 BPD (≤ 47,700 m^3/d)
Cooling Water ■ Hypochlorite: ≤5 ppm ■ Temperature (50°C/122°F at point of discharge)	≤1,900,000 BPD (≤ 302,100 m^3/d)
Sulfate Removal, Ultrafiltration, and Wash Water Processing Brines ■ Hypochlorite: ≤1 ppm ■ Electrolyte: ≤1 ppm ■ Biocide: ≤5 ppm ■ Oxygen Scavenger: ≤10 ppm ■ Scale Inhibitor: ≤5 ppm	≤315,000 BPD (≤ 50,100 m^3/d)
Subsea Hydraulic Fluid Discharge ■ Water soluble, low-toxicity	≤5 BPD (≤ 0.8 m^3/d)
FPSO Bilge Water	1,800 BPD (287 m^3/d)
Inert Gas Generator Cooling Water	Negligible
FPSO Slop Tank Water (includes off-specification oil from process and deck drainage)	Negligible
Miscellaneous Discharges including Desalinization Blowdown and Lab Sink Drainage	<10 BPD (<1.6 m^3/d)
Tanker Ballast Water	Maximum 629,000 bbl (100,000 m^3) total (at each tanker crude loading)
Blowout Preventer (BOP) System Testing Water-Soluble, Low-Toxicity Hydraulic Fluid	30 bbl (4.8 m^3) every 2 weeks
Grey Water	250 BPD (40 m^3/d)
Black Water (sewage)	85 BPD (13.6 m^3/d)
Food Preparation Wastes	<40 BPD (<6.4 m^3/d)
Firefighting Foam Monitor Testing Discharge	<6 bbl (<0.95 m^3) per year (at annual fire monitor testing event)

°C = degrees Celsius; °F = degrees Fahrenheit; bbl = barrel; BPD = barrels per day; ppm = parts per million; m^3/d = cubic meters per day; m^3 = cubic meters

[a] Effluent characteristics and volumes/rates are based on the preliminary Project design information available at the time of the EIA.

[b] During production line commissioning and planned and unplanned shutdowns

Cooling water, produced water, and brines from the Sulfate Removal Unit (SRU), ultrafiltration, and wash water reverse osmosis system (all associated with the production operations stage) are the main operational discharges that are significant enough to require an assessment of the extent of the discharge plume. Although the discharge of hydrotest water and commissioning fluids will occur over only a short time period during the SURF installation and commissioning stage, they were also included in the offshore discharge modeling as a conservative measure. Additionally, a scenario simulating a failure in the sewage treatment plant requiring all black water to bypass the macerator (and assuming it also bypasses the holding tank) and be discharged directly overboard via an emergency outfall was considered. The constituents considered from these discharges are listed in Table 3-2.

Table 3-2: Offshore Discharges and their Constituents Modeled

Discharge	Modeled Constituents
Cooling Water	■ Temperature ■ Residual chlorine
Produced Water	■ Temperature ■ Oil and grease ■ Residual production and water treatment chemicals (e.g., scale and corrosion inhibitors)
Sulfate Removal, Ultrafiltration, and Wash Water Processing Brines	■ Hypochlorite ■ Electrolyte ■ Biocide ■ Oxygen scavenger ■ Scale inhibitor
Hydrotest Water	■ Biocides ■ Oxygen scavenger ■ Corrosion inhibitor
Gas Injection Line Commissioning Fluid	■ Hydrate inhibitor (e.g., methanol or ethylene glycol)
Black Water	■ TSS ■ BOD_5 ■ Coliform bacteria

BOD_5 = 5-day biochemical oxygen demand

The model used is the U.S. Environmental Protection Agency's (USEPA) Cornell Mixing Zone Expert System (CORMIX) dilution model. CORMIX is a design tool routinely used by regulatory agencies to estimate the size and configuration of proposed and existing mixing zones resulting from wastewater discharges. CORMIX is primarily a near-field model (i.e., it applies to the region adjacent to the discharge structure in which the wastewater plume is recognizable as separate from the ambient water and its trajectory is dominated by the discharge rate, effluent density, and geometry of the discharge structure).

The CORMIX calculation is based on defining the various hydraulic zones the effluent plume traverses in the receiving waterbody, then applying an analytical solution or empirical relationship to compute the plume trajectory and dilution rate in each zone. Each of these analytical solutions and empirical relationships has been validated by the developers and other researchers against laboratory and field studies. CORMIX has been applied to many cases (http://www.cormix.info) and is recognized by the USEPA and other national regulatory agencies as an appropriate model for computing trajectories, dilution rates, and mixing zone dimensions.

To represent the short-term nature of the discharge for the untreated black water discharge scenario, the 3-D hydrodynamic and water quality model GEMSS® was used. Unlike CORMIX, the GEMSS model is capable of simulating temporally and spatially varying conditions.

3.2 Scenario Selection

Understanding the mixing characteristics of the various discharges and assessing compliance with applicable regulatory standards requires an understanding of the properties of the receiving (ambient) water. The properties of the ambient water, in combination with the discharge port configuration (pipe or diffuser), control the near-field mixing and dilution of the discharge. Properties of the ambient water relevant to the current analysis include current velocity, temperature, and salinity. While the ambient current velocity (and its strength relative to the discharge/exit velocity) determines the level of initial mixing, temperature and salinity influence the behavior of the discharge plume and its relative configuration due to density differences (i.e., buoyancy effects). Significant density differences between the discharge and ambient water will impede mixing. Balancing that effect, significant differences between discharge velocity and ambient current increase entrainment of the ambient water into the discharge plume, resulting in rapid mixing.

3.2.1 Discharge Velocity

Discharge velocity is directly related to the pipe diameter used for the various effluent streams. Smaller pipe diameters result in higher exit velocities, facilitating increased mixing. However, engineering constraints may require a minimum pipe diameter. As is typically the case for an EIA, details are not yet available for all aspects of the Project discharge design. However, detailed design information is available for the Destiny and Unity FPSOs; accordingly, where appropriate, design values from these projects were used for the analysis for the Yellowtail Project. If smaller discharge pipe diameters are used for the Yellowtail Project, the discharge will result in increased mixing and smaller plumes. A larger pipe diameter was also evaluated for some scenarios to confirm that the plume under a larger pipe will continue to meet the targeted environmental guidelines. The pipe configurations considered for the discharge streams modeled are listed in Table 3-3.

Table 3-3: Pipe Diameters Considered for Offshore Discharges

Type of Discharge	Pipe Diameter (inches/millimeters)	Vertical Location Relative to Sea Level
Produced Water	23 / 584.2	1 meter (3.2 feet) above water surface
Cooling Water	22.6 and 45.2 / 574 and 1,148.1	1 meter (3.2 feet) above water surface
Sulfate Removal, Ultrafiltration, and Wash Water Processing Brines	23 / 584.2	1 meter (3.2 feet) above water surface
Hydrostatic Test Water	2 and 6 / 50.8 and 152.4	Seafloor
Hydrate Control Fluid	2 and 6 / 50.8 and 152.4	Seafloor
Black Water	8 / 203.2	1 meter (3.2) feet below water surface

3.2.2 Discharge Properties

Discharge rates for the various operational discharges were based on the preliminary design (see Table 3-1). For modeling of hydrotesting discharges, SURF volumes were also based on preliminary design information. The discharge rates and SURF volumes reflect conservative (high) estimates. Anticipated constituent concentrations and temperatures in discharge streams were also based on preliminary design. The selected discharge rates and constituent concentrations are shown in Table 3-4.

Table 3-4: Modeled Discharge Properties

Type of Discharge	Modeled Discharge Rate	Modeled Parameter Values
Produced Water	300,000 BPD (48,000 m^3/d) (conservative)	■ Temperature: 55°C (131°F) ■ Oil and Grease: 42 mg/L (daily maximum) ■ Residual production and water treatment chemicals (100 ppm scale inhibitor and 200 ppm corrosion inhibitor used as examples)
Cooling Water	1,900,000 BPD (≤ 304,000 m^3/d)	■ Temperature: 50°C (122°F) ■ Hypochlorite: ≤5 ppm
Sulfate Removal, Ultrafiltration, and Wash Water Processing Brines	315,000 BPD (≤ 50,400 m^3/d)	■ Hypochlorite: ≤1 ppm ■ Electrolyte: ≤1 ppm ■ Biocide: ≤5 ppm ■ Oxygen scavenger: ≤10 ppm ■ Scale inhibitor: ≤5 ppm
Hydrostatic Test Water	65,000 bbl (10,400 m^3) (total volume for all flowlines and risers, occurring across approximately 1 year)	■ Biocide: 500 ppm ■ Oxygen scavenger: 100 ppm ■ Corrosion inhibitor: 200 ppm
Hydrate Control Fluid	2,500 bbl (400 m^3) (may be as low as 1,400 bbl [224 m^3])	■ Concentrated methanol or ethylene glycol
Black Water	3,960 gallons (15 m^3) per day [a]	■ TSS: 650 mg/L ■ BOD_5: 350 mg/L ■ Coliform: 10,000,000 CFU/100 ml

°C = degrees Celsius; °F = degrees Fahrenheit; bbl = barrel; BOD_5 = 5-day biochemical oxygen demand; BPD = barrels per day; CFU = colony-forming units; ml = milliliter; ppm = parts per million; m^3 = cubic meter; m^3/d = cubic meters per day
[a] Based on design capacity for black water (85 BPD) with 180 persons on board; 10 percent contingency factor applied.

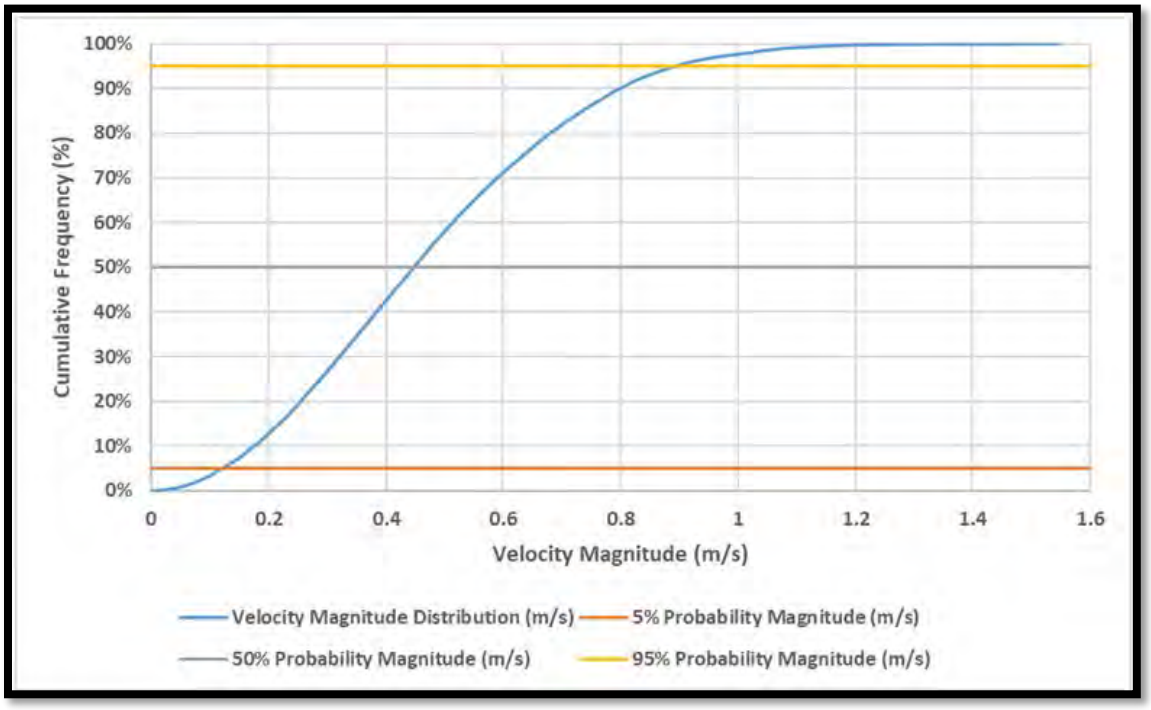
3.2.3 Ambient Currents

Ambient current velocities for the region were available from ExxonMobil Upstream Research Company using the SAT-OCEAN model and analyzed in order to select appropriate values for the specific locations for the discharges at the FPSO location. Although the operational discharges will occur near the surface, the hydrotesting and hydrate control fluid releases will occur near the seabed. Therefore, the ambient current velocities were analyzed to select appropriate values depending on the discharge being modeled.

Ambient current velocities were analyzed for the period of January 2005 to December 2014. A frequency distribution analysis was performed to evaluate the magnitude and exceedance percentages for current velocities. The ambient current velocities selected for modeling consisted of bounding cases (5 percent and 95 percent) and a typical case (50 percent). The frequency distributions for the two depths are shown on Figure 3-1 and Figure 3-2. The selected current velocities are shown in Table 3-5.

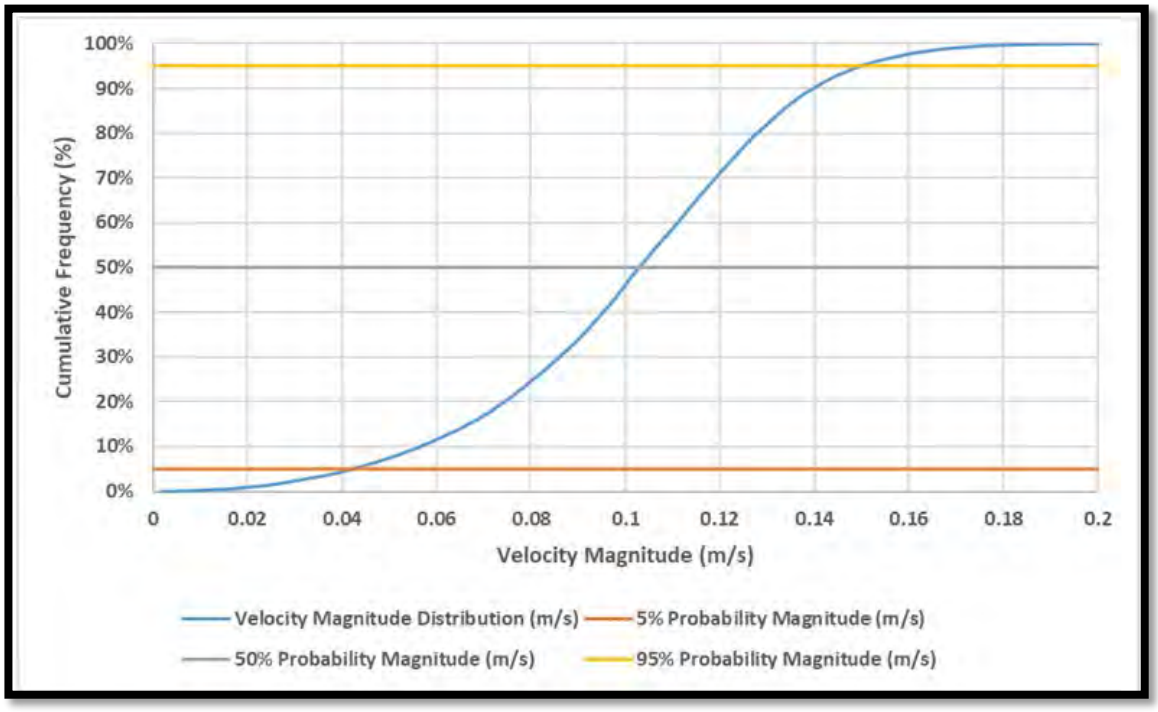
The use of a frequency distribution for selection of current velocities helps determine bounding cases for extreme ambient currents. The period of record is 10 years, which is sufficient to represent the variety in ambient conditions. Conditions outside of the ones observed during this 10-year period are expected to occur infrequently and, if they do occur, to not be sustained for long durations. Dynamics of the discharge plume under these unlikely conditions will therefore be rare and will quickly return to typical conditions due to the transitional nature of the currents. Furthermore, the model selected for analysis (CORMIX) has inherent conservativeness built in. It is thus reasonable to assume that the choice of bounding cases (5 percent and 95 percent) from the 10 years of record provides adequate representation of the likely discharge plumes that would predominate.

Figure 3-1: Cumulative Frequency Distribution for Current Velocities at FPSO Location (near surface)



m/s = meter per second

Figure 3-2: Cumulative Frequency Distribution for Current Velocities at FPSO Location (near seabed)



m/s = meter per second

Table 3-5: Selected Ambient Current Velocities (meters/second)

Cumulative Frequency	Surface	Seabed
Low (5%)	0.121	0.042
Typical (50%)	0.447	0.103
High (95%)	0.894	0.150

3.2.4 Ambient Temperatures

An analysis of ambient temperatures for the FPSO location was conducted based on data available from the HYCOM model. Since the ambient temperatures do not vary significantly within the Stabroek Block, only the FPSO location was considered. The temperature data are available for January 2013 to April 2018. A frequency distribution analysis was completed to evaluate the temperatures and exceedance percentages. Selected ambient temperatures consisted of two bounding cases (1 percent and 99 percent) and a typical case (50 percent). Only the cooling water discharge, whose plume is influenced by the ambient temperatures and whose flowrate is relatively high, was considered for the bounding cases and all remaining discharges were run for the typical case. The frequency distribution is shown on Figure 3-3 and the selected temperatures are shown in Table 3-6. For discharges released near the seafloor (hydrostatic test discharge), a single value of temperature at 4.5 degrees Celsius (ºC) (40.1°Fahrenheit [°F]) was used, as the temperature values near the seafloor do not vary considerably with time and space.

Figure 3-3: Cumulative Frequency Distribution for Temperatures at FPSO Location (near surface)

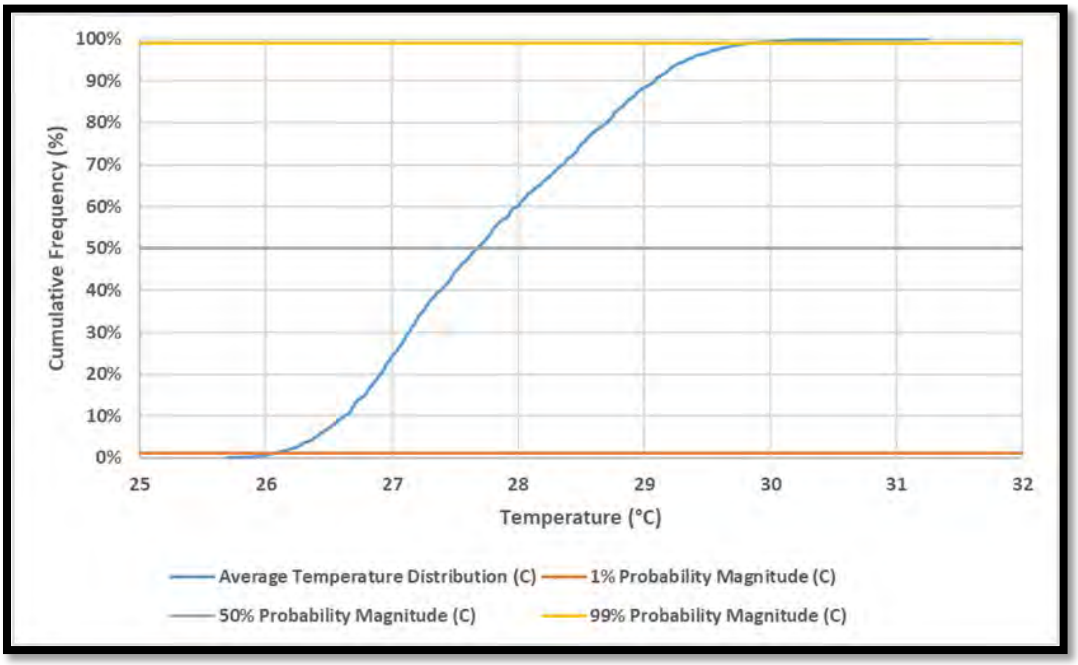


Table 3-6: Selected Ambient Near-Surface Temperatures (°C)

Cumulative Frequency	Temperature at FPSO Location
Low (1%)	26.07
Typical (50%)	27.68
High (99%)	29.89

3.2.5 Scenarios

A combination of the discharges, ambient properties (currents and temperatures), and discharge velocities (based on pipe diameters) were used to develop a comprehensive list of scenarios for simulation with CORMIX (Table 3-7). All potential pipe diameters listed in Table 3-3 were used to model these scenarios.

Table 3-7: List of Modeled Scenarios

No	Discharge	Scenario Name	Ambient Currents	Ambient Temperature	Location
1	Cooling Water—Thermal	T Sc. 01	Low (5%)	High (99%)	FPSO; 1 m above water surface
		T Sc. 02	Typical (50%)	High (99%)	FPSO; 1 m above water surface
		T Sc. 03	High (95%)	High (99%)	FPSO; 1 m above water surface
		T Sc. 04	Low (5%)	Low (1%)	FPSO; 1 m above water surface
		T Sc. 05	Typical (50%)	Low (1%)	FPSO; 1 m above water surface
		T Sc. 06	High (95%)	Low (1%)	FPSO; 1 m above water surface
2	Cooling Water—Hypochlorite	C Sc. 01	Low (5%)	High (99%)	FPSO; 1 m above water surface
		C Sc. 02	Typical (50%)	High (99%)	FPSO; 1 m above water surface
		C Sc. 03	High (95%)	High (99%)	FPSO; 1 m above water surface

No	Discharge	Scenario Name	Ambient Currents	Ambient Temperature	Location
		C Sc. 04	Low (5%)	Low (1%)	FPSO; 1 m above water surface
		C Sc. 05	Typical (50%)	Low (1%)	FPSO; 1 m above water surface
		C Sc. 06	High (95%)	Low (1%)	FPSO; 1 m above water surface
3	Sulfate Removal, Ultrafiltration, and Wash Water Processing Brines	W Sc. 01	Low (5%)	Typical (50%)	FPSO; 1 m above water surface
		W Sc. 02	Typical (50%)	Typical (50%)	FPSO; 1 m above water surface
		W Sc. 03	High (95%)	Typical (50%)	FPSO; 1 m above water surface
4	Produced Water	P Sc. 01	Low (5%)	Typical (50%)	FPSO; 1 m above water surface
		P Sc. 02	Typical (50%)	Typical (50%)	FPSO; 1 m above water surface
		P Sc. 03	High (95%)	Typical (50%)	FPSO; 1 m above water surface
5	Hydrostatic Test Water	H Sc. 01	Low (5%)	4.5°C	FPSO; seafloor
		H Sc. 02	Typical (50%)	4.5°C	FPSO; seafloor
		H Sc. 03	High (95%)	4.5°C	FPSO; seafloor

		MEG Sc03 6in	High (95%)	4.5°C	FPSO; seafloor

m = meter

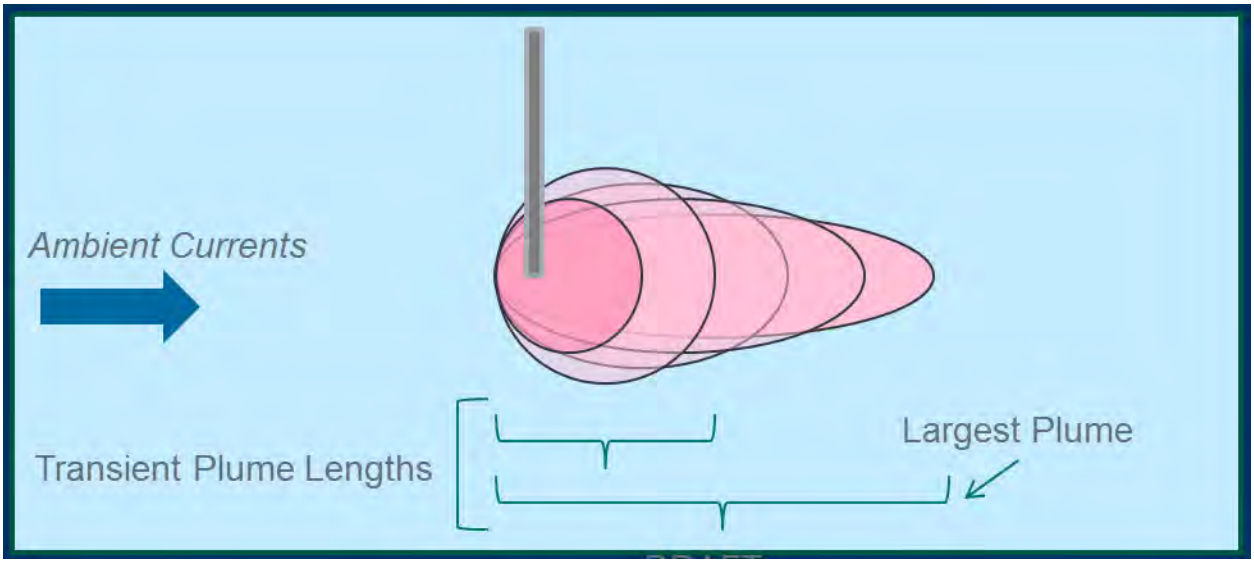
3.3 Standards and Thresholds

Cooling water discharges are typically regulated based on consideration of native aquatic species. These standards are more stringent in coastal and inland waters due to the presence of sensitive aquatic receptors and the limited area available for mixing. In offshore waters, such standards are usually absent. For this study, an internationally recognized thermal guidance of 3°C (5.4ºF) maximum temperature change at 100 meters (328.1 feet) from the point of discharge was used. Hypochlorite, added to cooling water to avoid biofouling, is either regulated as an end-of-pipe concentration or at the end of a mixing zone. However, due to the transient nature of the plume and absence of sustained exposure to residual chlorine, the hypochlorite is not expected to pose risk to biota. Although not technically applicable to a cooling water discharge, the assessment utilized the International Maritime Organization's *2012 Guidelines on Implementation of Effluent Standards and Performance Tests for Sewage Treatment Plant*s recommendation that when chlorine is used as a disinfectant, the best technical practice is to keep the disinfectant residual in the effluent below 0.5 mg/L (IMO 2012).

The scenarios designed in this study are highly conservative (i.e., they assume extended periods of time during which ambient conditions—primarily currents, salinity and temperature—persist). This approach assumes a static plume, which, in reality, will be transient in extent and configuration. For instance, the small ambient currents (5 percent bounding condition) will only exist for a short duration, as these currents only exist for 5 percent of the total time. In actuality, the currents will increase and decrease and the resulting plume will disperse more rapidly than the model predicts. Figure 3-4 shows a schematic of such a transient plume, where the extent and dilution continue to change as ambient currents decrease or increase. When modeling slower ambient current velocities (5 percent bounding condition), the analysis

will predict a more concentrated plume. However, this plume will exist for only a short duration, as velocities will change (increase), increasing dilution. Furthermore, the directionality of these currents will change the orientation of this transient plume, resulting in regions around the discharge that are only exposed to increased concentrations (or temperatures) for short durations.

Figure 3-4: Transient Discharge Plume from Various Offshore Releases



The end-of-pipe concentration of oil and grease in produced water is regulated by MARPOL73/78 standards at a maximum monthly average of 29 mg/L and a daily maximum of 42 mg/L. The USEPA compliance guidance document for the Gulf of Mexico (Final NPDES[4] General Permit for New and Existing Sources and New Discharges in the Offshore Subcategory of the Oil and Gas Extraction Category for the Western Portion of the Outer Continental Shelf of the Gulf of Mexico [GMG290000]) requires treatment chemicals such as biocides, corrosion inhibitors, or other chemicals used to prevent corrosion or fouling of piping or equipment to be limited by the following constraints (USEPA 2017):

- The maximum concentration and any other conditions specified in the USEPA product registration labeling; or
- The maximum manufacturer's recommended concentration; or
- 500 mg/L.

At the time of the study, no manufacturers' recommended limits are available for the SRU processing brines, produced water, or hydrotest water. It is noted that the maximum concentrations of any treatment chemicals in the discharge streams will be less than 500 mg/L.

With respect to the emergency black water discharge scenario, the International Maritime Organization's *2012 Guidelines on Implementation of Effluent Standards and Performance Tests for Sewage Treatment Plants* recommends the following standards for effluent discharge (IMO 2012):

- TSS should not exceed 35 mg/L.
- 5-day biochemical oxygen demand (BOD_5) should not exceed 25 mg/L.
- Thermotolerant coliforms should not exceed 100 colony-forming units (CFU) per 100 milliliters.

[4] National Pollutant Discharge Elimination System

Since no ambient water-quality standards are available for the various offshore discharge streams except for the guidance for temperature increase for the cooling water discharge, the assessment reports results in terms of percentage dilution at a reference distance of 100 meters (328.1 feet).

3.4 Results

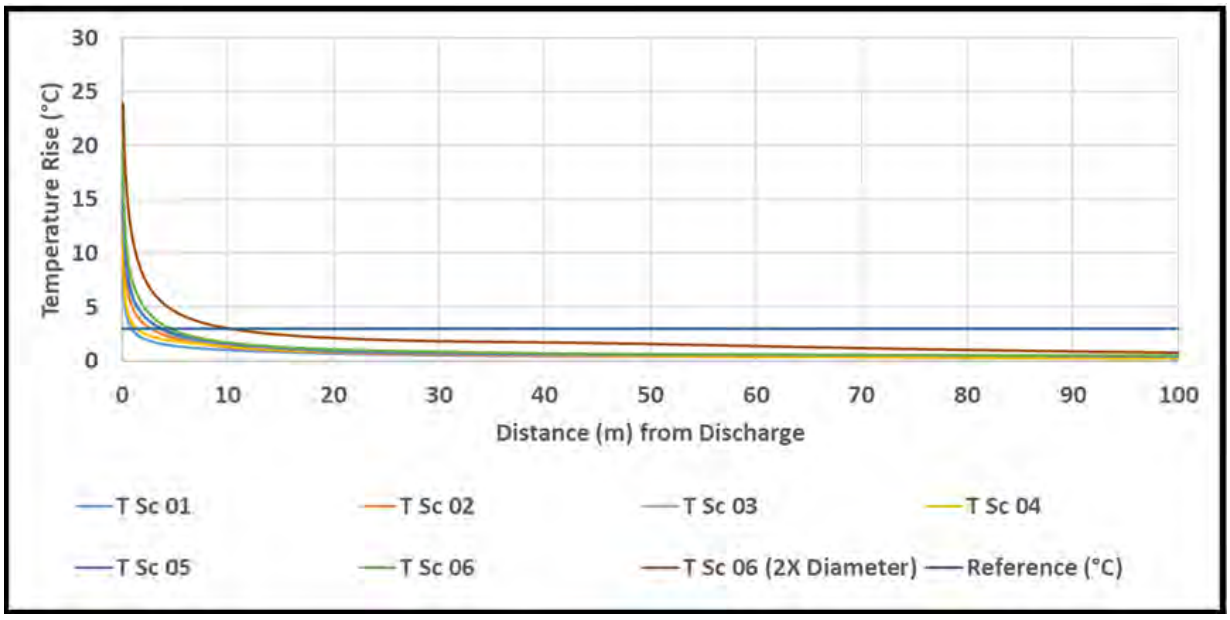
Each CORMIX simulation codes its results in a prediction (*.prd) file that consists of the plume centerline coordinates (0,0,0 at the discharge location), dilution (S) and concentrations. For thermal discharge (cooling water), concentration refers to the temperature rise above ambient and includes heat loss from the surface. For all other constituents, the dilution value does not include any decay and, therefore, represents a conservative (high) result. Inclusion of a decay term would result in a smaller plume. Since the concentrations are always the highest at the plume centerline, the results discussed here are shown as centerline concentrations at a particular distance directly down current from the discharge.

3.4.1 Cooling Water

The design of the cooling water discharge structure, at this early stage of the Project, is not finalized. However, information from the previous FPSOs (Destiny, Unity, and Prosperity) is available and was used as reference since these FPSOs will have similar overall design themes to that of the Yellowtail Project. The design will only consider pipe configurations that allow compliance with the thermal guideline of temperature rise within 100 meters (328.1 feet) of the discharge to be less than 3°C (5.4ºF). The previous FPSO designs were based on this guideline and, as such, provide a good basis for use in the Yellowtail Project, noting that the Yellowtail Project cooling water discharge rate is estimated to be 1,900,000 barrels per day (BPD), as compared to the Unity and Payara discharge rates (1,600,000 BPD). The discharge pipe diameter is currently expected to remain the same. This will tend to enhance the mixing of the discharge. Key to these design elements is the release of the discharge above the water surface, which results in significant gravitational acceleration and thus significant mixing at the point of entry into the ambient water. Two ambient temperatures (1 percent and 99 percent) were selected for simulation because different ambient temperatures will influence the plume behavior and the effluent temperature rise.

Based on the initial assessments, the scenario identified as T Sc. 06 (low ambient temperature and high ambient currents) was found to result in the longest distance for the plume to reach the temperature change threshold. This scenario was then re-run for a pipe diameter twice the size. Even with the diameter doubled (4 times the area), the thermal plume complied with the reference guideline of 3°C (5.4ºF) temperature change within 10 meters (32.8 feet) of the discharge. Figure 3-5 shows the temperature rise diminishing with distance from the discharge, showing compliance with the 3°C (5.4ºF) temperature change within 10 meters (32.8 feet) from the discharge for all scenarios.

Figure 3-5: Temperature Rise Above Ambient Versus Distance Downstream for All Scenarios



Compliance with the thermal discharge guideline requires sufficient mixing within the immediate vicinity of the discharge. The pipe configurations designed to ensure compliance for thermal guideline will therefore result in adequate mixing for the hypochlorite discharge as well. For the scenarios considered here, the worst case (lowest mixing) scenario (T Sc. 06 with 2X diameter) results in a dilution factor of 31.2 (23.93°C temperature rise / 0.768°C temperature rise) [43.1ºF temperature rise / 1.38ºF temperature rise]). This means that for this same scenario, for a hypochlorite dosing of 5 parts per million (ppm), hypochlorite concentrations will be 0.10 ppm at 100 meters (328.1 feet). As noted earlier, these concentrations represent conservative estimates (i.e., peak values) and will be transient in nature.

3.4.2 Produced Water

Produced water is characterized by an elevated temperature, and contains oil and grease and residual production and water treatment chemicals. Scale inhibitor and corrosion inhibitor were modeled at discharge concentrations of 100 ppm and 200 ppm, respectively, as examples of residual production chemicals that may exist in the produced water discharge. The pipe configuration (diameter and location) was assumed as 58.42 centimeters (23 inches) releasing at 1 meter (3.28 feet) above the water surface. Of the constituents of concern in produced water, only oil and grease end-of-pipe concentrations are regulated under MARPOL 73/78. The applicable standard is a maximum monthly average of 29 mg/L and a daily maximum of 42 mg/L, measured at the end of pipe. These standards are applied at the point of release of the produced water. The daily maximum value of 42 mg/L was therefore used as the discharge concentration for this analysis. The thermal guideline applied to cooling water (less than 3°C [5.4ºF] temperature rise within 100 meters [328.1 feet] of the discharge) was also applied to produced water.

Concentrations of oil and grease, scale inhibitor, and corrosion inhibitor are shown for the three scenarios (see Table 3-7) on Figure 3-6, Figure 3-7, and Figure 3-8, respectively. Oil and grease concentration decreases to less than 0.74 mg/L within 100 meters (328.1 feet) while scale inhibitor and corrosion inhibitor drop to less than 1.77 ppm and 3.54 ppm, respectively, within 100 meters (328.1 feet). The same level of mixing is expected for temperature rise, as seen on Figure 3-9, where the temperature rise drops to less than 0.48°C (0.86ºF) within 100 meters (328.1 feet).

Figure 3-6: Concentration of Oil and Grease (mg/L) with Distance (meters) from the Discharge for the Three Scenarios Modeled

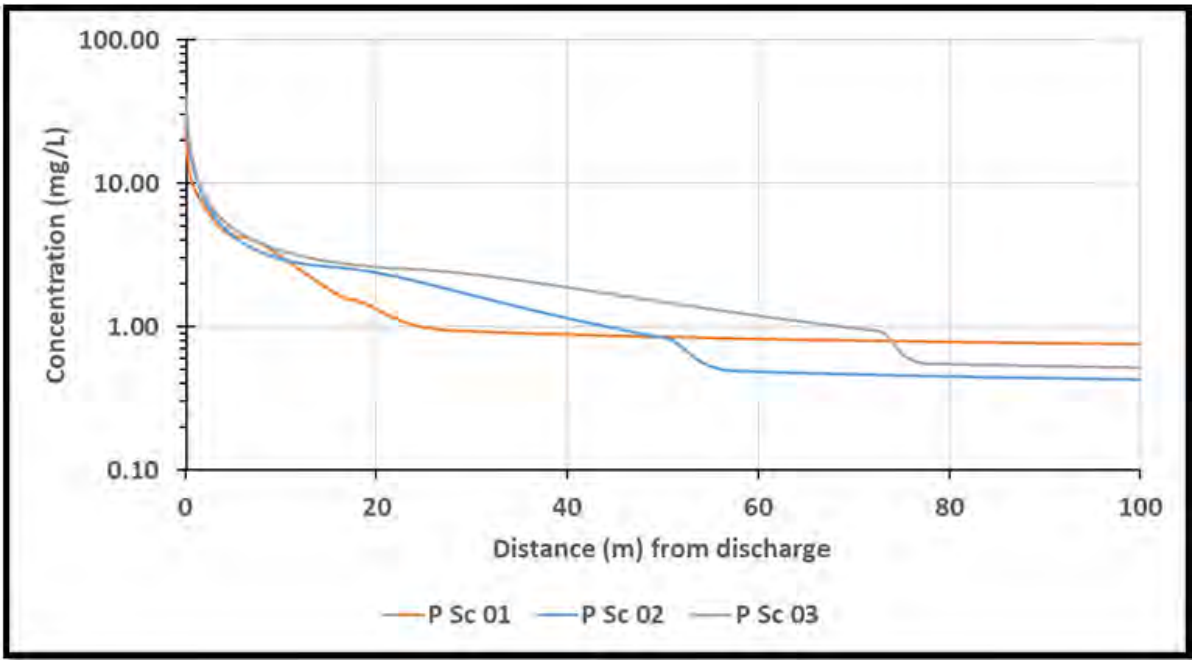


Figure 3-7: Concentration of Scale Inhibitor (ppm) with Distance (meters) from the Discharge for the Three Scenarios Modeled

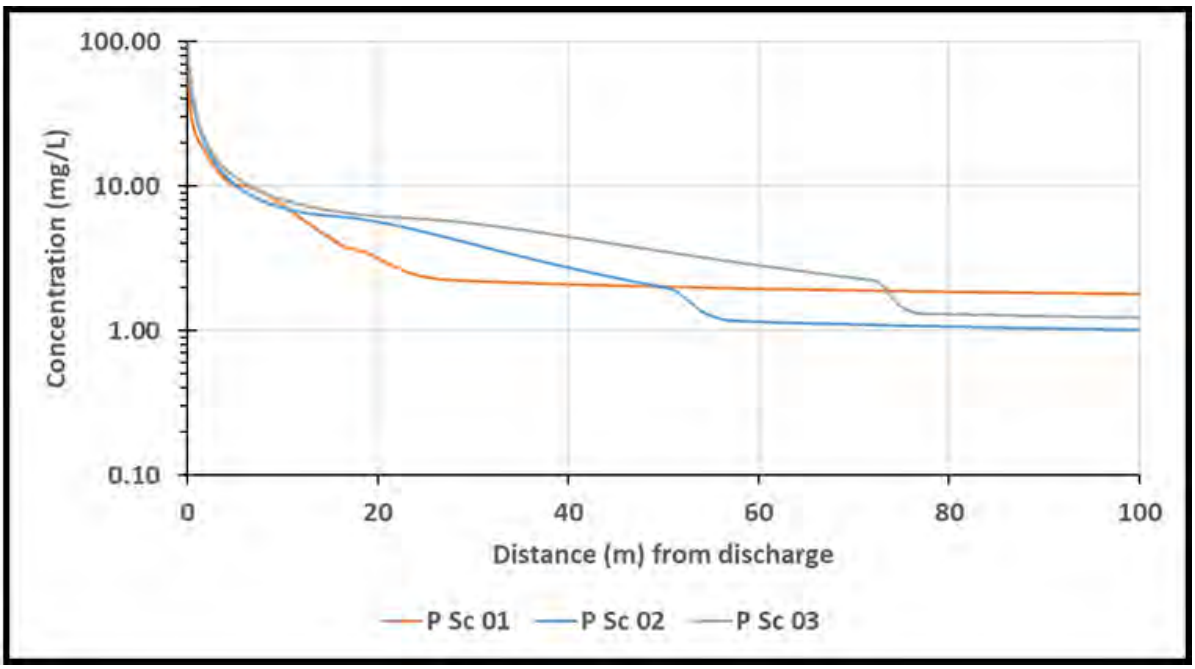

Figure 3-8: Concentration of Corrosion Inhibitor (ppm) with Distance (meters) from the Discharge for the Three Scenarios Modeled

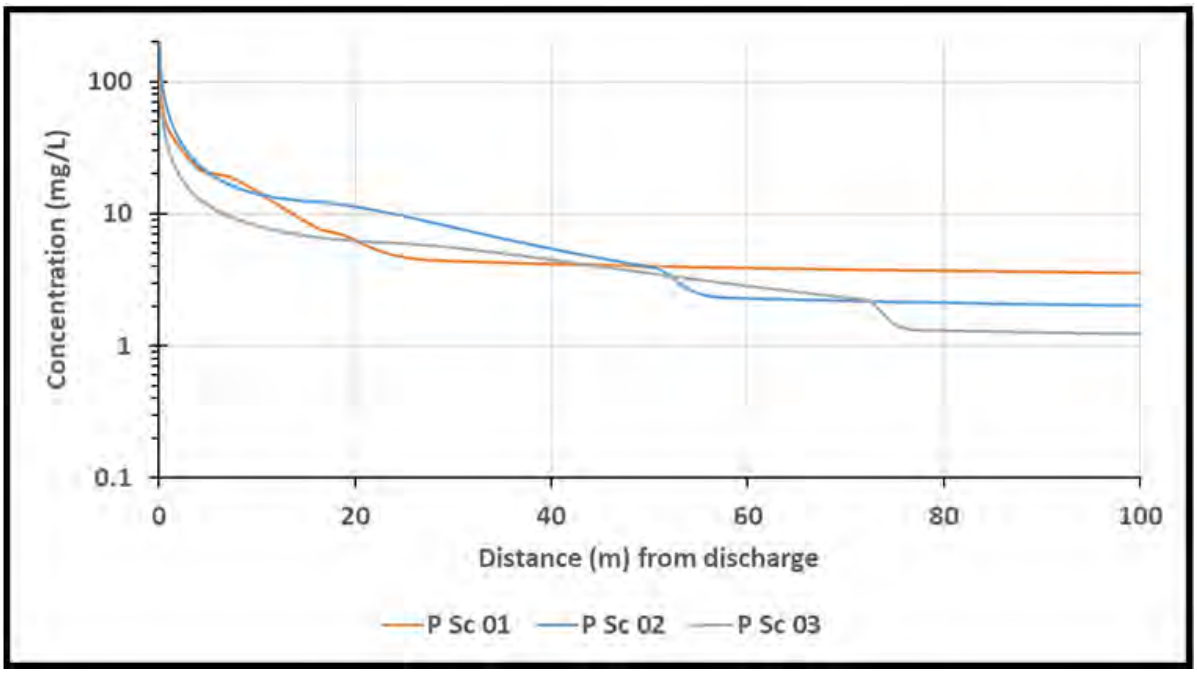

Figure 3-9: Temperature Rise with Distance (meters) from the Discharge for the Three Scenarios Modeled

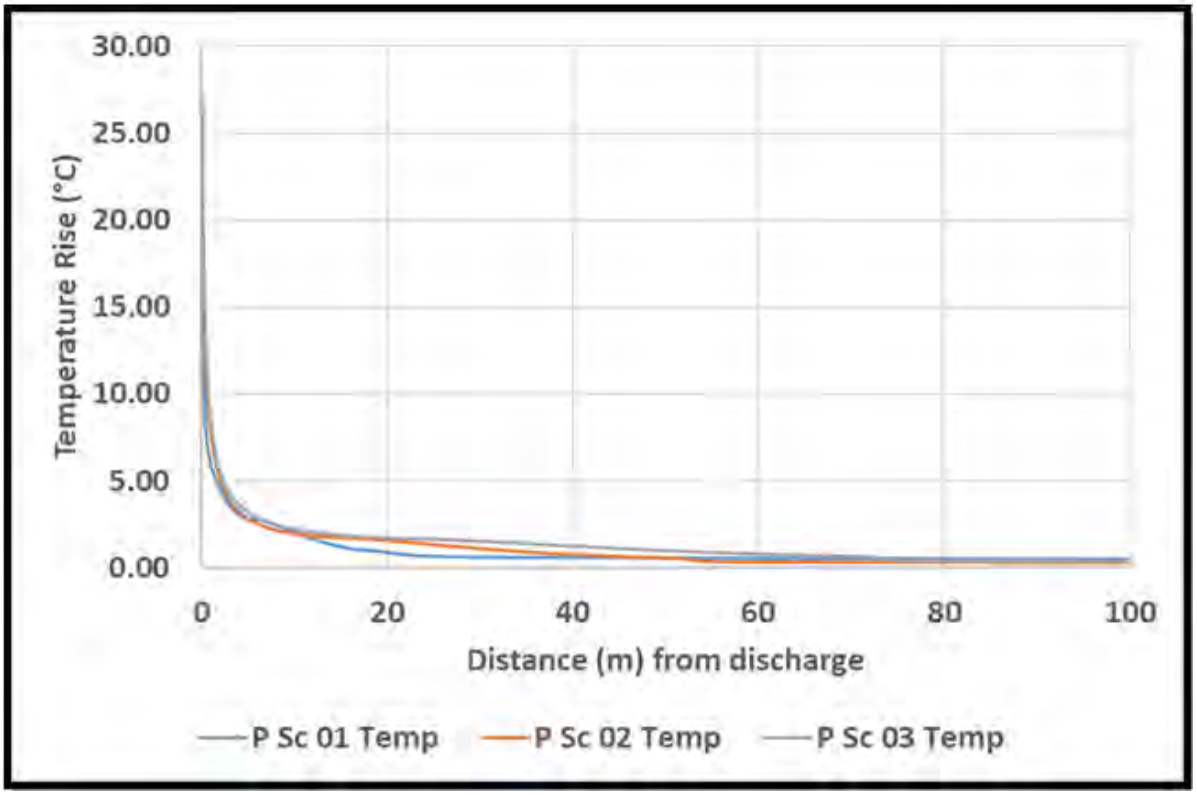
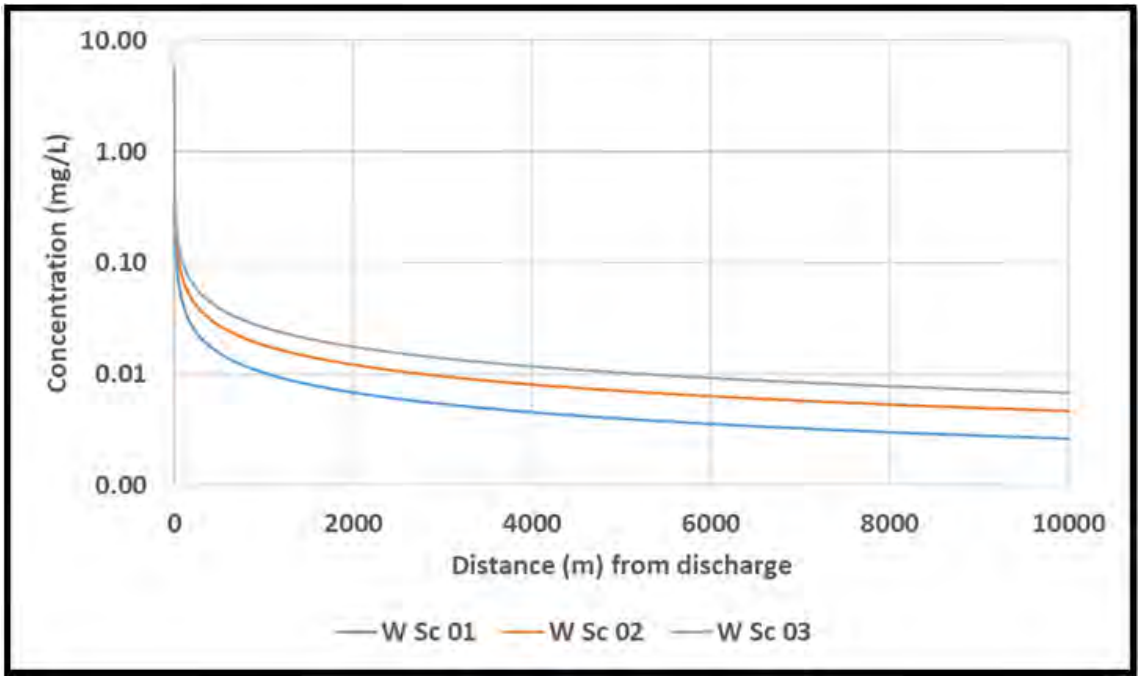


3.4.3 Sulfate Removal, Ultrafiltration, and Wash Water Processing Brines

This discharge stream consists of a combination of processing brines from the SRU, ultrafiltration, and wash water reverse osmosis system. The main constituents are hypochlorite, electrolytes, biocides, oxygen scavenger, and scale inhibitor. It was assumed that the discharge pipe will not exceed a diameter of 58.42 centimeters (23 inches), and that the stream will be released at least 1 meter (3.28 feet) above the water surface. Any pipe of smaller diameter will result in increased mixing and a smaller plume.

The predicted biocide concentrations for the three scenarios modeled (see Table 3-7) are shown on Figure 3-10. The biocide concentration decreases to no more than 0.094 mg/L within 100 meters (328.1 feet) and 0.026 mg/L within 1,000 meters (3,280.8 feet) (99.5 percent reduction) for the worst-case scenario (high ambient currents). All other constituents will follow the same mixing pattern and experience the same percent reduction.

Figure 3-10: Concentration of Biocide (ppm) with Distance (meters) from the Discharge for the Three Scenarios Modeled

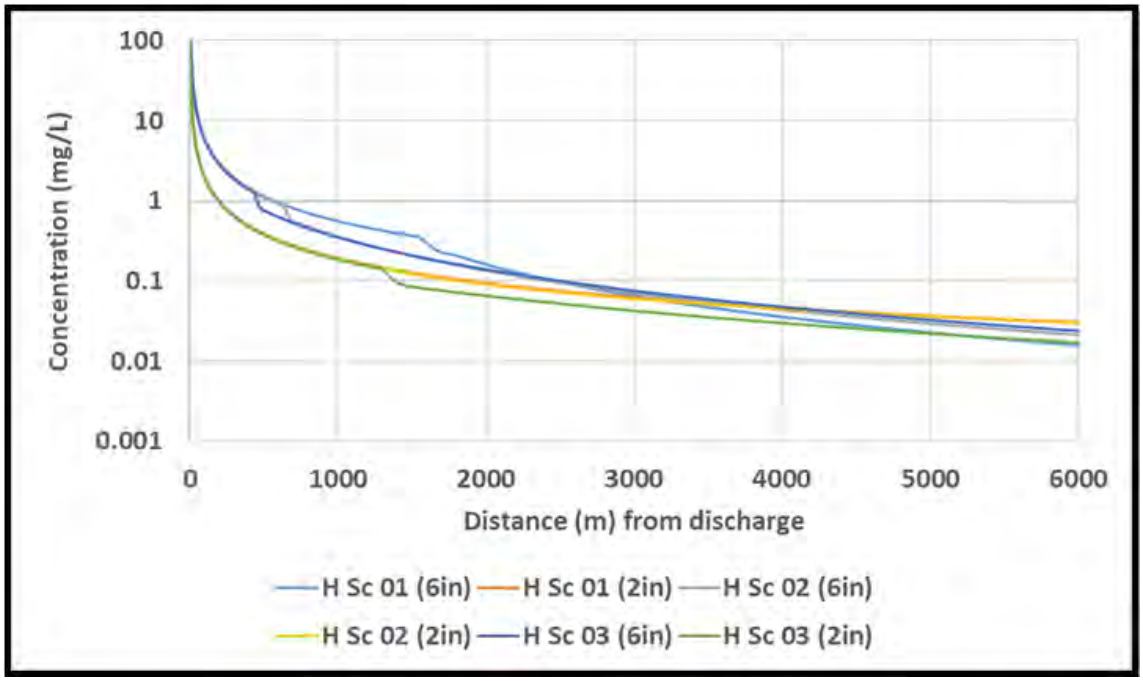


3.4.4 Hydrostatic Test Water

Hydrotesting is a necessary process to test for the integrity of the various subsea pipelines and risers prior to putting them in service for production operations. This is a critical procedure that is required for offshore projects of this nature. All pipeline and riser volumes were considered for this analysis and the largest single release was selected for modeling. It was assumed that once testing is complete, the total volume will be released within 60 minutes. Since the pipelines and risers are of different diameters, all three scenarios were run for pipe diameters of 5.1 centimeters (2 inches) and 15.2 centimeters (6 inches). Results for all three scenarios showing reduction in biocide concentration with the bounding pipe diameter cases are shown on Figure 3-11. For the worst case scenario (H Sc. 01 with 15.2-centimeter [6-inch] pipe), biocide decreases to 5.77 ppm within 100 meters (328.1 feet) of the discharge.

The other constituents (oxygen scavenger and corrosion inhibitor) will follow the same mixing pattern and experience the same percent reduction.

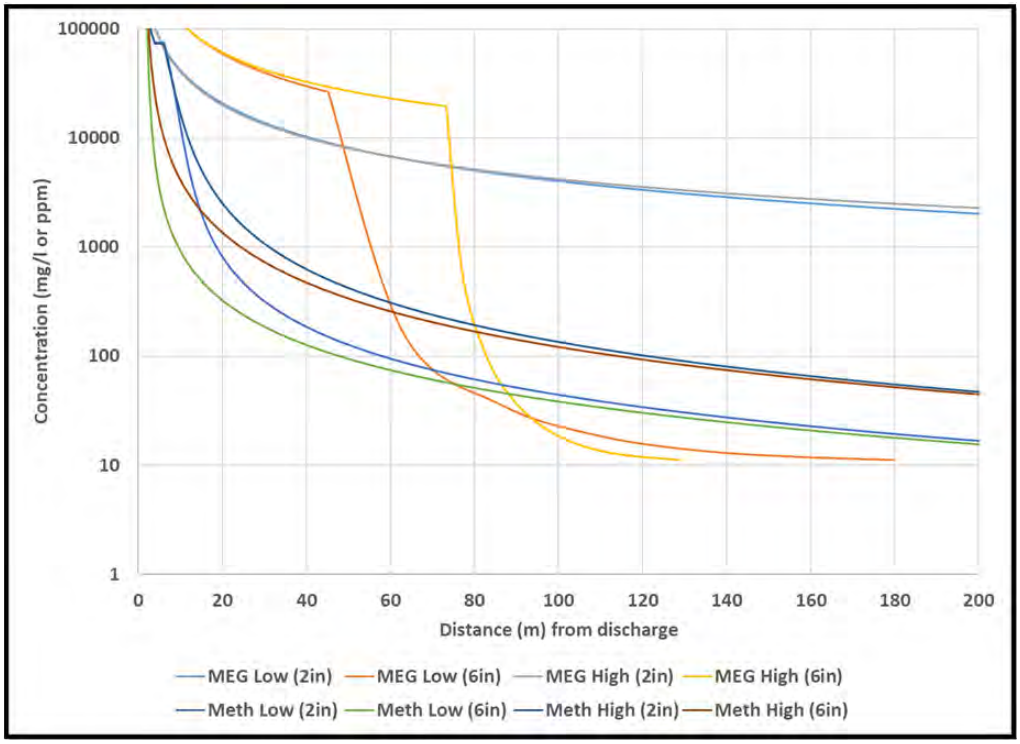
Figure 3-11: Concentration of Biocide (ppm) with Distance (meters) from the Discharge for the Three Scenarios and Two Pipe Diameters



3.4.5 Gas Re-injection Line Commissioning Fluids

As part of the gas re-injection line commissioning, a hydrate control fluid (concentrated methanol or ethylene glycol) will be discharged at the seafloor. The most probable volume for the hydrate control fluid will be 1,400 barrels (bbl) (224 cubic meters [m^3]), but a conservative value of 2,500 bbl (400 m^3) was assumed for the modeling analysis. Since the pipelines and risers are of different diameters, all three scenarios were run for pipe diameters of 5.1 centimeters (2 inches) and 15.2 centimeters (6 inches). Figure 3-12 shows the results for both methanol and ethylene glycol under the low and high ambient currents and 5.1-centimeter (2-inch) and 15.2-centimeter (6-inch) pipe diameters.

Figure 3-12: Concentration of Methanol or MEG (ppm) with Distance (meters) from the Discharge for the Low and High Currents and 2-inch and 6-inch Pipe Diameters



3.4.6 Black Water

An emergency scenario where an upset occurs for the onboard black water treatment system was considered. Under this emergency scenario, it was assumed that untreated black water from accommodations and the clinic would bypass the macerator and the sewage holding tank and be discharged directly overboard through an emergency outfall. The FPSO is designed for a maximum of 180 persons on board, with a black water design capacity of approximately 85 BPD (13.6 cubic meters per day [m^3/d]). Applying a contingency factor of 10 percent resulted in the modeled sewage generation and emergency discharge rate of 3,960 gallons per day (15 m^3/d).

The untreated black water experiences instant mixing once it enters the ambient water. Although the constituents (BOD_5, TSS, and coliform) are released at high concentrations, immediate mixing and dilution results in steep declines in concentrations with distance. Due to the selected model resolution, this steep decline cannot be captured visually on the model results representation. The highest concentrations can only be reported as volume-averaged within the first modeled grid cell, which covers a volume of 200 cubic meters (10 meters x 10 meters x 2 meters), although higher peak concentrations will exist within this cell (<10 meters from the discharge).

Figure 3-13 shows the modeled maximum BOD_5 concentration across the model domain. As shown on the figure, there is no region in the modeling domain with a predicted BOD_5 concentration above 25 mg/L. Figure 3-14 shows the modeled maximum concentrations of TSS across the model domain. As shown on the figure, there is no region in the modeling domain with a predicted TSS concentration above 35 mg/L.

Figure 3-15 shows the modeled maximum concentrations of coliform across the model domain. As shown on the figure, there is no region in the modeling domain with a predicted coliform concentration above

100 CFU per 100 milliliters. Further analysis of modeling results indicates that by 3 hours after the cessation of the discharge, the coliform concentration drops to less than 1 CFU per 100 milliliters.

3.5 Conclusions

Various operational and maintenance discharges and activities were modeled to estimate the extent of the associated discharge plumes. Extreme conditions and maximum expected discharge rates and concentrations were considered in this conservative analysis. The only relevant regulatory guideline related to ambient water quality is for the thermal discharges: temperature rises within 100 meters (328.1 feet) of the discharge point are recommended to be less than 3°C (5.4ºF). Since the Project is in a preliminary design phase, design specifications for the various discharge ports were not available. To address this lack of specific information, conservative estimates of the largest feasible pipe diameter were made, and modeling simulations were used to confirm that these upper-bound diameters will allow the guidelines to be met.

CORMIX, a near-field mixing zone model approved by USEPA, was used to model the various discharges (aside from the untreated black water discharge). It was found that even under upper-bound conditions discharge plumes were relatively small and subject to rapid mixing within the first 100 meters (328.1 feet). Although only thermal discharges are subject to regulatory limits, the reference distance of 100 meters (328.1 feet) is used for reporting purposes for all the discharges to demonstrate the rapid mixing that the discharge plumes experience. Table 3-8 summarizes the results of the modeling study for the planned offshore discharges.

Additionally, based on modeling of an untreated black water discharge using the GEMSS model, maximum concentrations of BOD_5, TSS, and coliform remain below the thresholds of 25 mg/L, 35 mg/L, and 100 CFU per 100 milliliters, respectively.

		MEG High 6in	MEG (6-inch [15.2-cm] pipe): pure chemical at 1,115 kg/m^3	MEG (6-inch pipe): 18.34 ppm

[a] Except for the thermal discharge (temperature rise), no standards exist for the listed discharge constituents. The distance of 100 meters (328.1 feet) is used as a reference distance to report dilution, and should not be interpreted as a criterion for regulatory compliance.

4. CUMULATIVE IMPACTS: OFFSHORE DISCHARGES

The Yellowtail Project will initiate after the Liza Phase 1, Liza Phase 2, and Payara Projects, and activities for the four Projects will therefore overlap in time. Although the Yellowtail Project's FPSO will be approximately 30.8 kilometers (19.1 miles) away from the Liza Phase 1 Project FPSO, 22.5 kilometers (14 miles) away from the Liza Phase 2 Project FPSO, and 41 kilometers (25.5 miles) away from the Payara Project FPSO, modeling was conducted to assess whether there is a potential for cumulative impacts on water quality due to simultaneous offshore discharges from the respective developments. The CORMIX model is limited in its ability to appropriately include other local or regional discharges and the resulting plume interactions. To address this limitation, and to appropriately quantify cumulative impacts from these four FPSOs, a separate 3-D hydrodynamic and water quality model was applied. The GEMSS model is capable of simulating temporally and spatially varying conditions, and can incorporate any number of discharges into one single model simulation. This section describes the use, application, and results of the GEMSS model for the cumulative impact analysis.

4.1 GEMSS

GEMSS® is an integrated system of 3-D hydrodynamic and transport modules embedded in a geographic information and environmental data system. GEMSS is in the public domain and has been used by the U.S. Bureau of Reclamation, Washington State Department of Ecology, Norwegian Institute of Water Research, Royal Institute of Sweden, and other international organizations.

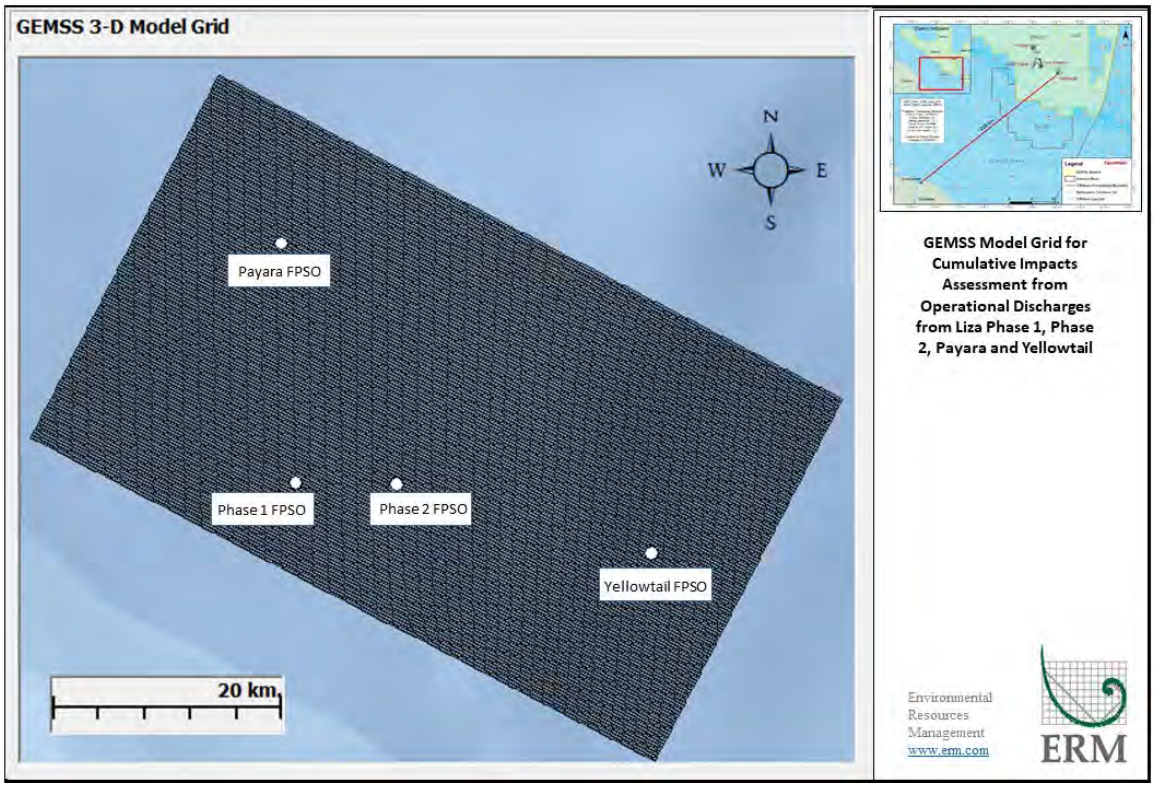
The theoretical basis of the hydrodynamic kernel of GEMSS is the 3-D Generalized, Longitudinal-Lateral-Vertical Hydrodynamic and Transport (GLLVHT) model, which was first presented in Edinger and Buchak (1980) and subsequently in Edinger and Buchak (1985). The GLLVHT computation has been peer reviewed and published (Edinger and Buchak 1995; Edinger et al. 1994 and 1997; Edinger and Kolluru 1999). The kernel is an extension of the well-known longitudinal-vertical transport model written by Buchak and Edinger (1984) that forms the hydrodynamic and transport basis of the United States Army Corps of Engineers' water quality model CE-QUAL-W2 (USACE 1986). Improvements to the transport model, construction of the constituent modules, incorporation of supporting software tools, GIS interoperability, visualization tools, graphical user interface, and post-processors have been developed by Kolluru et al. (1998; 1999; 2003) and Kolluru and Fichera (2003).

GEMSS and its component modules have met agency approval among federal and state governments within the United States. GEMSS has also been approved by regulatory agencies in the Bahamas, Qatar, India, Australia, Canada, and other countries.

4.2 Model Domain

A 3-D model such as GEMSS requires specification of a model domain that defines the boundaries of the region of interest. Based on the CORMIX modeling assessment, the region of interest around each of the FPSO discharges is very small due to the small sizes of the plumes. However, for the cumulative impact assessment, it is important to have a model domain that covers the region, including all operational discharges (i.e., all four FPSOs). The model domain, therefore, was selected as a region that would cover the four FPSOs and have sufficient region beyond these FPSOs to allow discharge plume spreading. The model domain, including the model computational grid and the locations of the FPSOs, is shown on Figure 4-1. The selected model domain is large enough to accommodate all operational discharges from the four FPSOs to assess cumulative impacts within a single model simulation.

Figure 4-1: Cumulative Impact Assessment Model Domain and Computational Grid



km = kilometer

4.3 Model Setup

As discussed in Section 3, there are several discharges from each FPSO. All of these discharges were included within a single GEMSS model simulation. Inclusion of all of these discharges for all four FPSOs affords the ability to perform a cumulative impact assessment by determining the overall extent of the discharge plumes within the modeled region. A key parameter in the assessment was the temperature rise above ambient, as there is thermal load associated with cooling water streams and produced water discharge from each of the FPSOs. There is potential for overlap of the thermal discharge plumes in the near-field for each FPSO, as the plumes from cooling water and produced water from a given FPSO may theoretically interact; further, the thermal plumes from separate FPSOs may also overlap. Although the individual assessments of the discharges performed in Section 3 show relatively small extents for these plumes, the lower values (<3ºC [5.4ºF] temperature rise) could theoretically combine to reach levels above 3ºC (5.4ºF) temperature rise. Both cooling water and produced water discharges were included in the model. Furthermore, the sulfate removal, ultrafiltration, and wash water processing brines discharges also were included in the model.

The model was configured such that the boundaries of the model computation grid received available time-varying temperature and salinity data from the HYCOM model and available time-varying water surface elevations from the SAT-OCEAN model. These data provide the necessary input for the GEMSS model to perform hydrodynamic and transport computations within the model computational domain. Each of the discharges was specified to the details available as shown in Table 4-1.

Table 4-1: List of Discharges and their Characteristics included in the GEMSS Model for Cumulative Impact Assessment

Offshore Discharge	Liza Phase 1 FPSO	Liza Phase 2 FPSO	Payara FPSO	Yellowtail FPSO
Cooling Water				
Flow, kBPD (m^3/d)	227 (36,320)	1,600 (256,000)	1,600 (256,000)	1,900 (304,000)
Temperature, ºC	50	50	50	50
Produced Water				
Flow, kBPD (m^3/d))	114 (18,240)	300 (48,000)	300 (48,000)	300 (48,000)
Temperature, ºC	55	55	55	55
Oil and Grease (mg/L)	42	42	42	42
Sulfate Removal, Ultrafiltration, and Wash Water Processing Brines				
Flow, kBPD (m^3/d)	100 (16,000)	265 (42,400)	265 (42,400)	315 (50,400)
Hypochlorite (ppm)	1	1	1	1

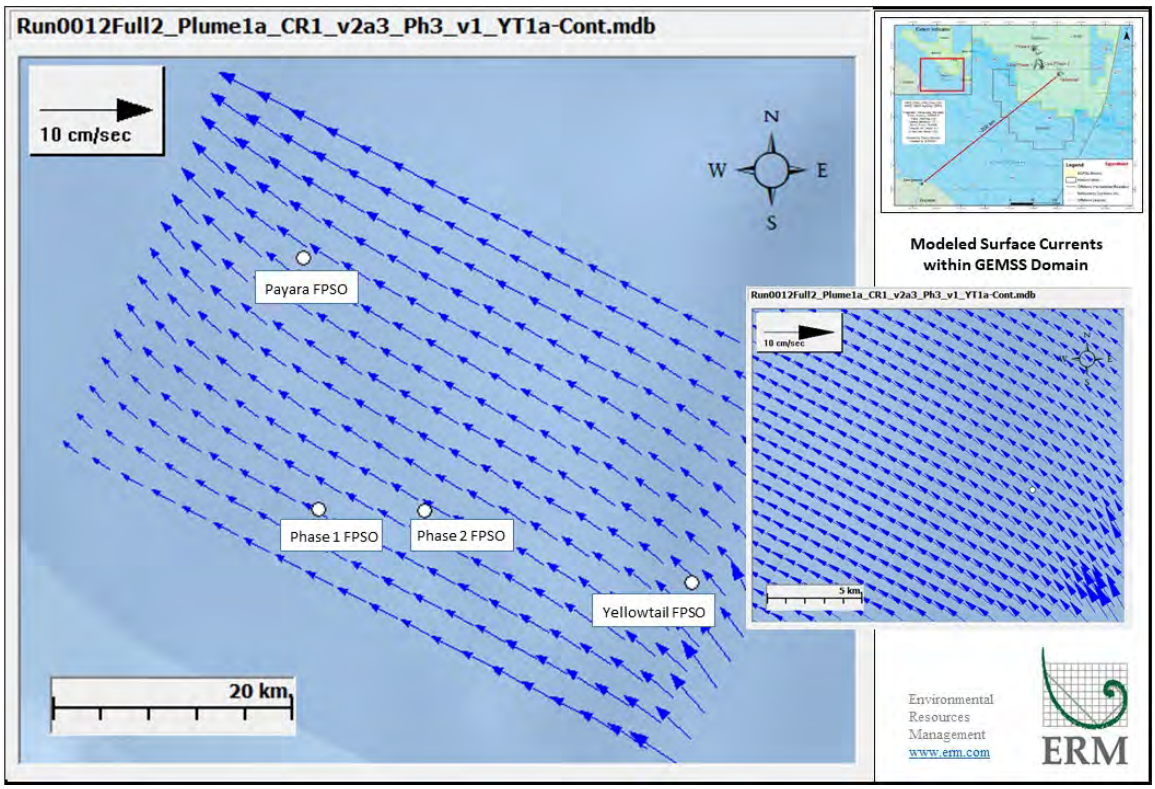
kBPD = thousand barrels per day

The model was run for a period of 28 days, which included a period of 7 days for model "spin-up." Model spin-up is defined as a time during which the computational model ramps up from stagnant condition to realistic conditions, as forced by the conditions specified at the boundaries. All model results were summarized statistically to obtain worst-case conditions (i.e., maximum concentrations during the entire model simulation period).

4.4 Model Results

The model, under conditions specified through the boundaries, provides results that consist of currents, water surface elevations, temperature, salinity, temperature rise above ambient, oil and grease concentration, hypochlorite concentration, and concentration of a dye constituent. A dye constituent was included in the model simulation so that concentrations of any constituents could be estimated by scaling the dye concentrations to the discharge values. The modeled currents were consistent with the known circulation pattern in the region (see Section 6.4.2.1, Oceanographic Conditions, of the Yellowtail EIA). The results show a strong Guiana Current toward the northwest (see Figure 4-2).

Figure 4-2: Snapshot of Modeled Hydrodynamics within the GEMSS Model Domain



km = kilometer
Note: The four white dots denote the locations of the four modeled FPSOs. The main image shows lower resolution and inset shows full resolution to demonstrate overall circulation patterns and strength.

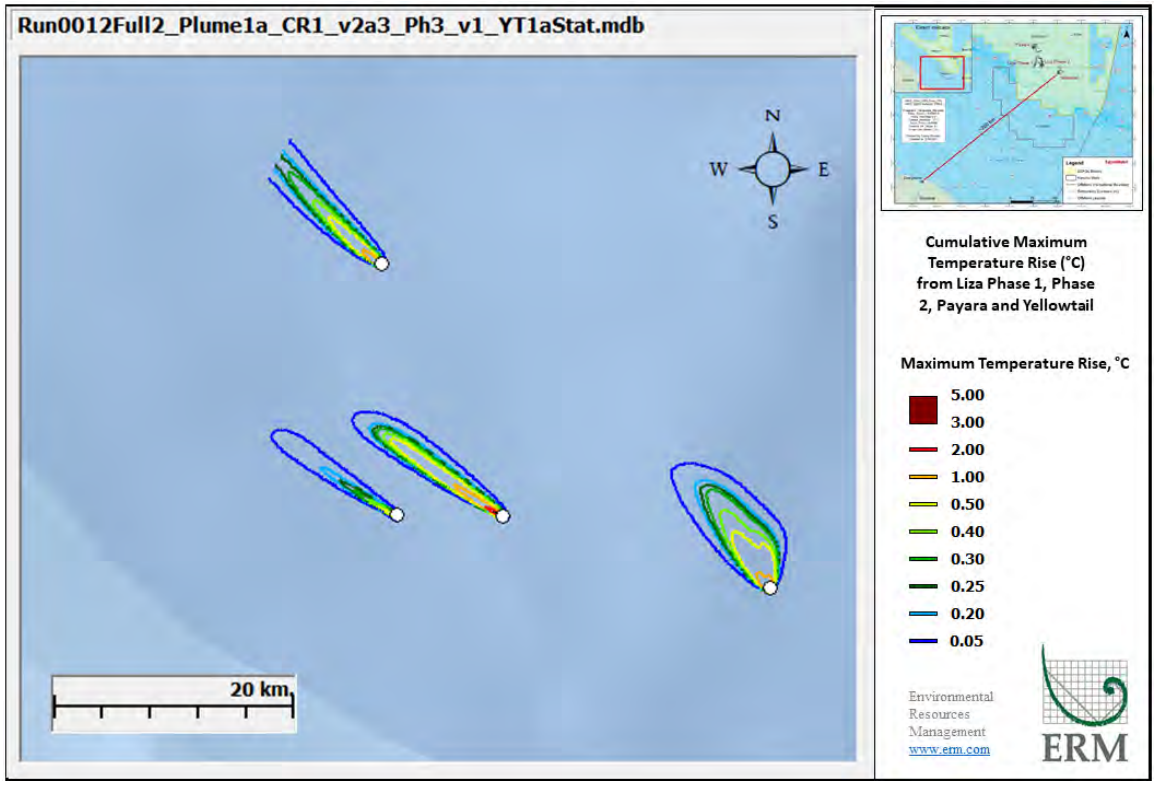
4.4.1 Temperature Rise

As noted earlier, a key parameter in the assessment is the temperature rise above ambient associated with the thermal plumes from the FPSOs. The reference guideline of no more than 3ºC (5.4ºF) temperature rise above ambient beyond 100 meters (328 feet) was used to evaluate if any region within the entire computational domain (outside of the 100-meter [328-foot] distance from each FPSO discharge) was predicted to experience a temperature rise above 3ºC (5.4ºF). To evaluate if such a condition exists, the statistical maxima of the temperature rises above ambient were computed during the entire model simulation period. Note that the map showing the statistical maxima (Figure 4-3) only shows the maximum values, but this does not mean these maximum values occurred at the same time. Different maximum values at different locations could have occurred at different times during the simulation period. However, they were evaluated within a single map (i.e., assuming they all occurred at the same time) to evaluate the potential of any region reaching the maximum temperature rise above ambient.

Figure 4-3 shows the maximum temperature rise above ambient across the model domain. The color scale uses a hybrid approach, where all temperature-rise iso-lines below 3ºC (5.4ºF) are unfilled, and all temperature-rise iso-lines above 3ºC (5.4ºF) are filled with a designated color. As shown on the map, there is no region in the modeling domain with a predicted temperature rise above 3ºC (5.4ºF). The blue iso-lines that extend between the FPSOs denote a 0.05ºC (0.09ºF) temperature rise. Individual snapshots (representing actual predicted conditions across the domain at a given time) show plumes much smaller than the statistical maxima; Figure 4-4 shows four such snapshots. Based on these results, it is clear that no thermal plume overlapping occurs and that all four FPSOs operating concurrently will result in

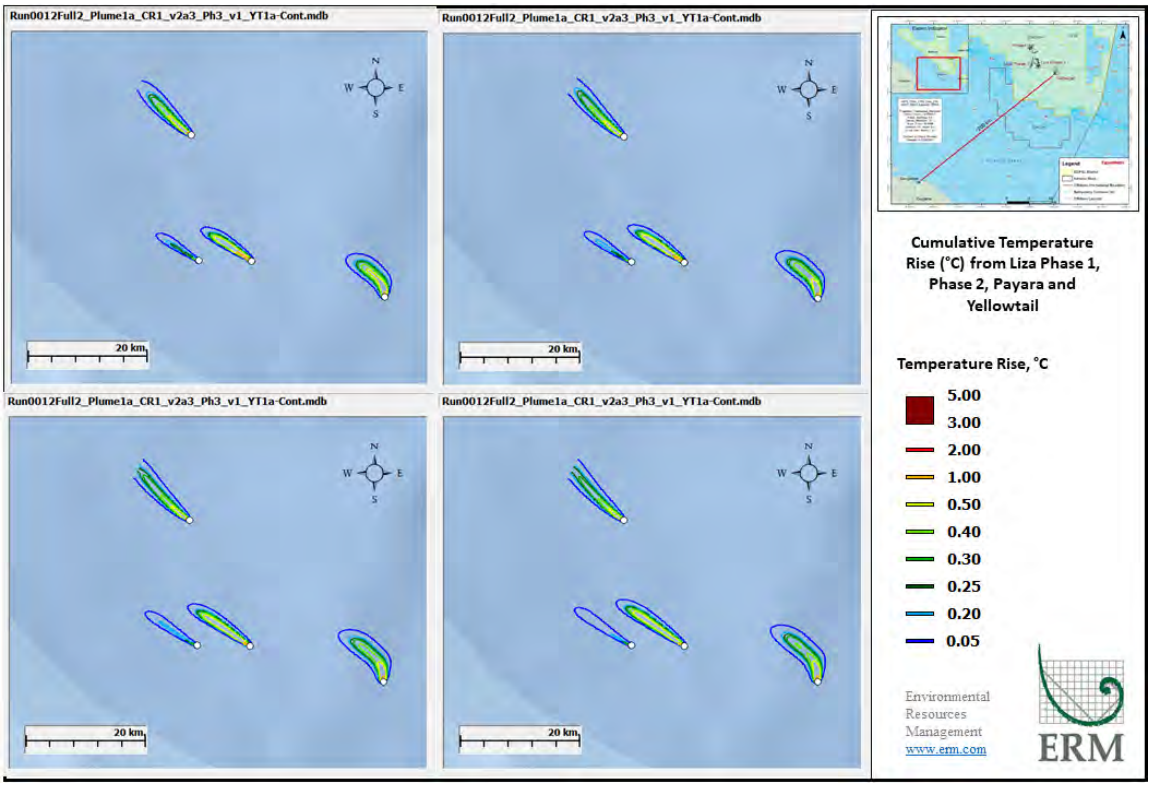
conditions that adhere to the <3ºC (<5.4ºF) temperature rise beyond 100 meters (328.1 feet) reference guideline.

Figure 4-3: Modeled Maximum Temperature Rise above Ambient when All Discharges (all Four FPSOs with Cooling Water and Produced Water) are Operational



km = kilometer

Figure 4-4: Example "Snapshots" of Modeled Time-Varying Temperature Rise above Ambient at Different Times (Every 6 Hours) during a Day

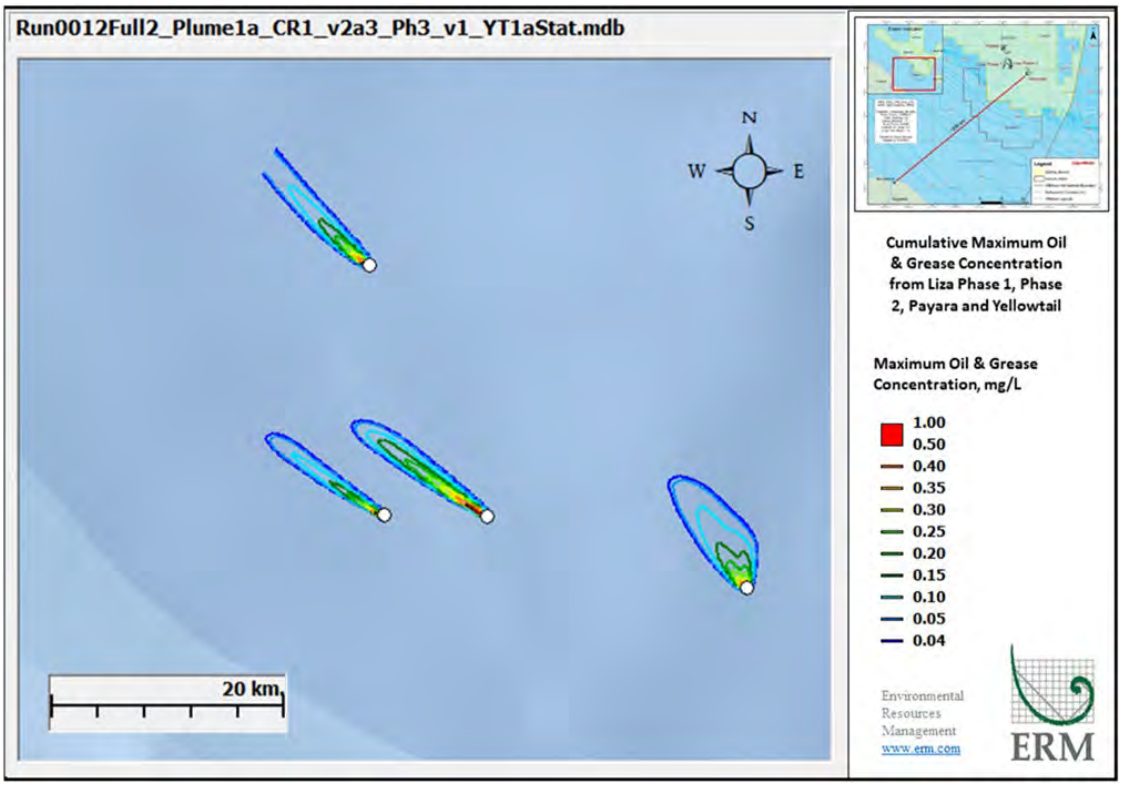


km = kilometer

4.4.2 Oil and Grease

Oil and grease is a constituent within the produced water that is limited to a daily maximum discharge value of 42 mg/L. Similar to the temperature rise above ambient, modeling of oil and grease concentrations shows that the produced water plumes experience rapid dilution and mixing, with no overlap between the discharges of the four FPSOs. Figure 4-5 shows the modeled maximum concentration of oil and grease in the model domain. The closest of the outermost iso-lines extending from each FPSO (0.04 mg/L) are more than 3 kilometers (1.9 miles) apart.

Figure 4-5: Modeled Maximum Oil and Grease Concentrations from Produced Water Streams of all Four FPSOs

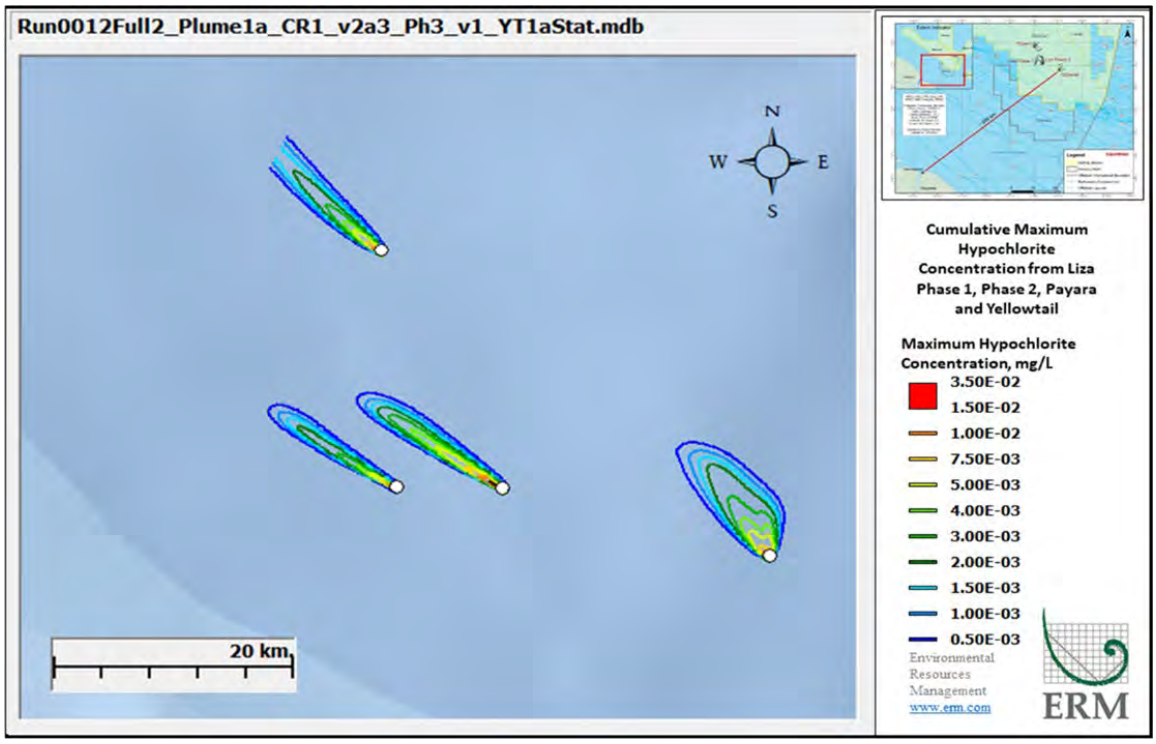


km = kilometer

4.4.3 Hypochlorite

Hypochlorite is a constituent included in both cooling water and sulfate removal, ultrafiltration, and wash water processing brines discharge. As noted earlier, there are no standards for hypochlorite in offshore waters. Similar to temperature rise and oil and grease, hypochlorite experiences rapid dilution and mixing once discharged. Figure 4-6 shows the maximum-modeled concentrations of hypochlorite during operation of the four FPSOs. The color scale is chosen to show the modeled plume and its potential to overlap. The color scale range is 0.0005 ppm to 0.035 ppm and even at these low values, there is no plume overlap.

Figure 4-6: Modeled Maximum Concentrations of Hypochlorite during Operation of all Four FPSOs

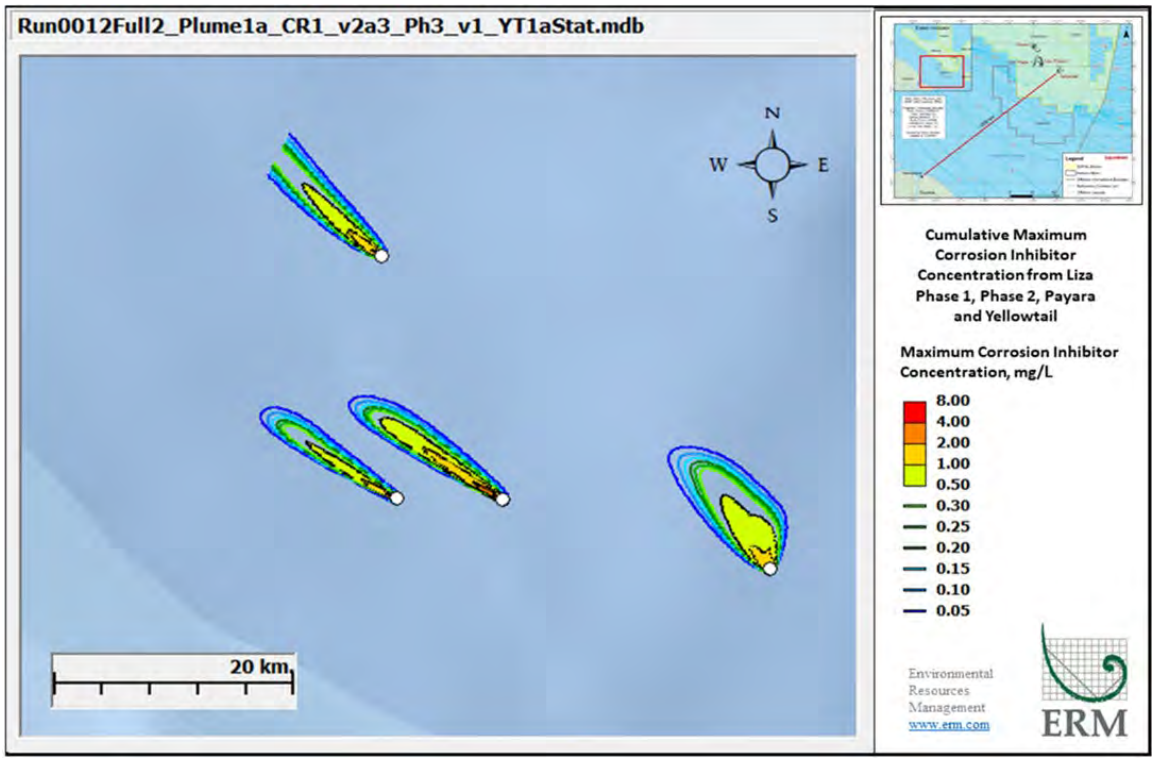


km = kilometer

4.4.4 Other Chemicals

In addition to temperature rise, oil and grease, and hypochlorite, the various discharge streams include other production chemicals such as corrosion inhibitor and scale inhibitor. These constituents experience similar rapid mixing and dilution as the other constituents described above. Modeling indicates the plumes do not overlap, even when mapping at extremely low concentrations. An example of modeled maximum concentrations for corrosion inhibitor is shown on Figure 4-7, where even iso-lines at 0.05 ppm show no overlap.

Figure 4-7: Modeled Maximum Concentrations of Corrosion Inhibitor



km = kilometer

4.5 Sensitivity Testing

In addition to the conservative assessment under low currents described earlier, a high-current scenario was also simulated to assess the trajectory of the plumes under other conditions. Time series plots, shown on Figure 4-8 and Figure 4-9, were created to determine the current magnitude for each scenario. Figure 4-8 shows the period of low currents (for which results are described in Section 4.4, Model Results) and Figure 4-9 shows the period of high currents. A snapshot of the modeled hydrodynamics within the GEMSS model domain for the high-current scenario is shown on Figure 4-10. Figure 4-11 shows the maximum temperature rise above ambient across the model domain. These plumes are significantly smaller than the plumes discussed above for the conservative low-current scenario. Note that similar to the results presented in Section 4.4, these plumes are statistical maxima. Individual snapshots (representing actual predicted conditions across the domain at a given time) show plumes much smaller than these statistical maxima; Figure 4-12 shows an example of four such snapshots. Figure 4-13 shows the modeled maximum concentrations of oil and grease in the model domain from produced water discharges. Figure 4-14 shows the maximum-modeled concentrations of hypochlorite during operation of the four FPSOs. Lastly, an example of modeled maximum concentrations for corrosion inhibitor is shown on Figure 4-15. In summary, the plumes under high currents are significantly smaller than the low current conditions for which results are presented in Section 4.4.

5. CUMULATIVE IMPACTS: DRILLING OPERATIONS

Similar to the operational discharges during production operations, drilling operations for the Yellowtail Project may occur simultaneously with drilling for other EEPGL development projects as well as EEPGL exploration drilling in the Stabroek Block. Although the footprint of drill cuttings deposition from drilling operations and the extents of associated TSS plumes are very limited, and are confined to within a close proximity of the respective drilling locations, an assessment was performed to evaluate the potential for cumulative impacts (overlap) from simultaneous drilling activities.

Figure 5-1 shows the locations of previously drilled EEPGL exploration/appraisal wells in the Stabroek Block, as well as proxy locations for future exploration wells in the Stabroek Block (selected for the purpose of this assessment based on exploration prospect areas identified in the previously approved Environmental Assessment & Management Plan for the Stabroek Block 25-well Exploration Campaign). Figure 5-1 also shows the previously drilled development well locations for the Liza Phase 1 and Liza Phase 2 Projects (the nearest development wells to the Yellowtail Project drill centers). As shown on Figure 5-2, the smallest distance between an exploration/appraisal well and a Yellowtail drill center is 1.07 kilometers (0.67 mile). Results of the drill cuttings modeling (see Section 2) shows that this distance of 1.07 kilometers (0.67 mile) exceeds the distance the cuttings deposition footprint or TSS plume would extend from a well. Similarly, the closest Liza Phase 1 or Liza Phase 2 development well to a Yellowtail drill center is a Liza Phase 2 well (LIZ-4P14), which is approximately 26 kilometers (16.2 miles) away from the nearest Yellowtail drill center. This distance also is significantly larger than the distance a drill cuttings deposition footprint or TSS plume extends from a well.

Furthermore, temporal aspects should also be considered in evaluation of the cumulative impacts. The threshold of sedimentation is 5 centimeters (2 inches) of deposition over a period of 30 days. For a combined deposition to result in cumulative impacts—even if the wells were close enough together to have overlapping deposition—another drilling operation would have to occur during the same 30-day period as a Yellowtail development well drilling operation. It is not likely that two such wells in such close proximity would be drilled within the same 30-day period. Similarly, the TSS plumes from drilling are highly ephemeral and will disperse rapidly under the ambient currents, resulting in a very low potential for any overlap with a TSS plume from another nearby drilling operation.

6. CONCLUSIONS

Spatially and time-varying modeling of potential cumulative impacts due to operations-stage discharges from four FPSOs was performed using the GEMSS model. The modeling included the major operational discharges assessed for the Yellowtail Project and assessed the potential for the Yellowtail discharge plumes and the plume from the same discharges for the other three modeled FPSOs to overlap and result in cumulative impacts. As shown on Figure 4-3 through Figure 4-7 and in Table 3-4, none of the modeled plumes showed potential for overlap—even when mapping to relatively small outer limits on the plumes. Modeling of all four FPSOs operating, with each FPSO discharging both produced water and cooling water (both of which add a thermal load), predicted no overlap in plumes. In the case of temperature rise, the outer edge of the mapped plumes from each FPSO was defined as a temperature rise of 0.05ºC (0.09ºF) (see Figure 4-3 and Figure 4-4). Modeling demonstrates that even at this level, there is no expected overlap of thermal plumes during simultaneous FPSO operations.

The potential for overlapping of drill cuttings deposition footprints and associated TSS plumes from Yellowtail drilling operations and other EEPGL drilling operations was also assessed. Based on consideration of the closest distance anticipated between two drilling locations, there is no potential for overlap in either drill cuttings deposition footprints or drilling-related TSS plumes (even under the very unlikely scenario were nearby drilling operations were conducted simultaneously).

1. INTRODUCTION

In 2016, ExxonMobil's affiliate, Esso Exploration and Production Guyana Limited (EEPGL), applied to the Guyana Environmental Protection Agency (EPA) for an Environmental Authorisation for the Liza Phase 1 Development Project in the Stabroek Block, offshore Guyana. On 1 June 2017, the Guyana EPA approved the Environmental Impact Assessment (EIA) submitted as part of the Application for Environmental Authorisation and issued an Environmental Permit for the Liza Phase 1 Development Project. As a condition of the Environmental Permit, the EPA required EEPGL to "conduct fishery-dependent studies in the nearshore zone augmented by fishery-independent studies in the nearshore and offshore zones...to develop a more complete understanding of the marine fish community outside the Liza Area of Interest." These studies were mandated to cover at least one wet and one dry season. EEPGL complied with this requirement by conducting a year-long fish study, the first year of which was completed in 2018 (ERM 2018a; ERM 2019). To supplement the fishery-dependent information collected during the first year of study, EEPGL implemented a program focused primarily on engagement with the artisanal fishing community, to serve as another approach to collecting baseline fisheries data.

EEPGL contracted with Environmental Resources Management (ERM), which partnered with the local Guyanese firm Environmental Management Consultants (EMC), to collaboratively execute a Participatory Fishing Study (herein referred to as the "study") to characterize the nektonic community (with a focus on fisheries) and map the principal local fisheries activities offshore Guyana. As part of the study, ERM and EMC engaged with local fisherfolk who agreed to participate on a volunteer basis (with a small stipend offered to cover any expenses) and provide data on their catch. The study had two primary components:

1. **The Coastal Landing Site Assessment** focused on data and photos of overall daily catch and catch characteristics (number of species, sizes, weights, etc.) at various coastal landing sites. Six regional supervisors from different landing sites in all six of the coastal regions participated in the study. The regional supervisors had experience in the area and knowledge of native species.
2. **The Local Artisanal Fishing Activities Assessment** focused on data, Global Positioning System (GPS) information, and photos of individual artisanal fishing activities, including daily catch, catch characteristics (number of species, sizes, weights, etc.), and routes to preferred fishing zones. Twelve onboard supervisors from two separate landing sites in each of the six coastal regions participated in the study.

Data collection efforts and subsequent analysis and assessment continued over the life of the study, covering the period from January 2019 through March 2020. These engagement efforts were the responsibility of EMC's biodiversity and fisheries project manager and a socioeconomics consultant (referred to herein as the study team). ERM provided international expertise on the methodology and data collected and analysis, including marine biology, socioeconomics, and imagery. This final report on the study provides the following:

- An introduction to the approach, methodology, and topics covered in the study;
- A characterization of the different types of fishing gear and vessels commonly used by artisanal fisherfolk in Guyana;
- A comprehensive analysis of data collected from the supervisors throughout the study;
- A comparative analysis of data collected from supervisors to identify key trends based on different fishing practices and seasonal variations;
- Graphic representation of preferred fishing grounds by onboard supervisors based on geographic information system (GIS) data collected while fishing; and
- Provision of species list along with photos for ease of fish identification (see Appendix A).

2. APPROACH AND METHODOLOGY

2.1 Selection of Landing Sites

From January 2019 to April 2019, the study team conducted initial field visits to landing sites along the coast from Regions 1 to 6. The primary purpose of these initial field exercises was to validate the selection of landing sites to be included in the study, but also to initiate engagement with fisherfolk to volunteer as potential regional and onboard supervisors. The team also took advantage of this early time at the landing sites with fisherfolk to collect landing site-specific baseline data (discussed in Section 2.3).

A total of 16 unique landing sites in Regions 1 to 6 were selected, as presented in Table 2-1. Figure 2-1 provides a map of the landing sites.

Landing sites were selected in each of the regions based on a combination of factors. The landing sites were selected to provide a representative spread of artisanal fishing activities based on the types of vessels and fishing gear used, target species, the duration of fishing trips, and the number of fisherfolk using the landing site. The selection process was guided by the knowledge and experience of the study team as well as the findings of an Ecosystem Services Study conducted as part of the Liza Phase 1 post-permit studies (ERM/EMC 2018). The selection of the landing sites was finalized based on the findings of the study's baseline data collection exercise.

Table 2-1: Landing Sites Selected in Regions 1 to 6

Landing Sites Selected for Regional Supervisors	Landing Sites Selected for Onboard Supervisors
Region 1—Smith's Creek/Morahwanna[1]	Region 1—Smith's Creek;[a] Waramuri/Haimokabra
Region 2—Charity	Region 2—Lima; Hampton Court
Region 3—Zeeburg	Region 3—La Grange; Windsor Forest
Region 4—Riverview (Unity, Mahaica)	Region 4—Riverview (Unity, Mahaica); Ogle
Region 5—Mahaicony Bridge	Region 5—Rosignol; Bushlot
Region 6—Rose Hall	Region 6—Complex 66; Albion

[a] The regional supervisor in Region 1 collected data from both Smith's Creek and Morahwanna. The onboard supervisor operating from Smith's Creek only operated from Smith's Creek; no onboard supervisor was located in Morahwanna.

2.2 Selection of Regional and Onboard Supervisors

During the initial field visits, two sets of supervisors were selected for the two different components. Regional supervisors were selected for the Coastal Landing Sites Assessment and Onboard Supervisors were selected for the Local Artisanal Fishing Activities Assessment. The methodologies used to select the supervisors are provided below and the questionnaires used for these selection processes are provided in Appendices B and C.

2.2.1 Regional Supervisors

The study team interviewed fisherfolk at each of the selected landing sites to determine interest level and relevant experience for participating in the study. Key criteria for the selection of a regional supervisor included, but was not limited to the following: specific experience in the area; leadership status and relationship with the relevant fishing cooperatives (co-ops) or organization(s) and individual fisherfolk operating at the site; and knowledge of native species. Individuals selected as regional supervisors were

nominated by the members of the fishing co-op (if there was one at the landing site) or by the fishing community in general—at landing sites without a co-op. The questionnaire was administered to the nominated individual to assess their level of experience and knowledge against a set of criteria. Once the nominee had satisfactorily satisfied the requirements outlined in the questionnaire, he/she was selected as a regional supervisor. If the nominee at a landing site did not satisfy the requirements, there was further engagement with the fisherfolk or co-ops to identify another suitable candidate.

The study team selected six voluntary regional supervisors at six different landing sites—one in each of the six coastal regions. Each regional supervisor was provided with a digital camera and a data sheet for which they would be given a monthly stipend to document daily catch of all fishing activity at their landing site. The program allowed for the provision of up to 20 daily catch records per month. The regional supervisor's role was to initially collect the registered fishing effort and associated data (gear type, bycatch, etc.) at their landing site, along with the catch characteristics (number of species, sizes, weights, etc.). Daily information from the landing site was then collected and entered into the provided data sheets (see Appendix D).

The study team also conducted several quality assurance and quality control (QA/QC) exercises to assess whether the regional supervisors were following the required methods for collecting data at their landing site. Over the course of the study, two QA/QC exercises were conducted (discussed in Section 2.6). If a regional supervisor did not satisfactorily or accurately collect data for their landing site (as determined through the QA/QC process) or opted to withdraw as a volunteer, a new regional supervisor was selected guided by the process and criteria outlined above. During the first round of QA/QC exercises, one regional supervisor was found to have falsified data sheets and was subsequently replaced.

2.2.2 Onboard Supervisors

The study team selected at least two boats/fisherfolk from two different landing sites in each of the six coastal regions. Each supervisor was provided with a GPS, a digital camera, and a simple one-page data sheet and given a monthly stipend to document their own daily catches—providing up to 20 data sheets per month. Like the regional supervisors, fishing co-ops were engaged, where they existed, to aid in the selection of the boats/fisherfolk at each landing site. At other sites, individual fisherfolk or the fishing community at large were engaged in the selection process. The selection process ensured there was a balanced representation of the offshore artisanal fishery sector, including a variety of vessel types based on fishing gear used, species targeted, and preferred fishing grounds. Once the vessels types were selected, onboard supervisors were assessed using the same questionnaire as for the selection of regional supervisors to test their knowledge of fishing. If the potential supervisor did not satisfy the requirements, there was further engagement with the fisherfolk or co-ops to identify another candidate.

During the QA/QC exercises (discussed in Section 2.6), random assessments of fisherfolk vessels occurred. In the event that an onboard supervisor did not satisfactorily or accurately collect data for their vessel (as determined through the QA/QC process) or opted to withdraw as a volunteer, a new onboard supervisor was selected guided by the process and criteria outlined above. Due to challenges encountered by the onboard supervisor at the Smith's Creek landing site (Region 1) (described further in Appendix F), an additional supervisor was selected mid-way through the program to augment data collection and improve the data pool in that region.

2.3 Baseline Data Collection

During the selection of landing sites and the training of regional and onboard supervisors, the study team also took advantage of time at the landing sites from January to April 2019 to collect baseline data. The baseline data collection consisted of a landing site assessment during which fisherfolk were interviewed

to determine number of vessels operating at the landing site, target species, typical catch composition, frequency of fishing trips, fisherfolk-preferred fishing ground, and where hauls are typically sold. At landing sites that had been shortlisted for inclusion in the study, the study team also solicited recommendations from fisherfolk on potential regional and onboard supervisors for the respective landing sites.

The baseline data collection efforts occurred during the off-peak season for fishing activities along the coastline (see Appendix E for data collection periods). As a result, at some of the larger landing sites, only a small number of fisherfolk who normally use the site were present to participate in the baseline data collection survey. Nonetheless, the baseline data collection was important to the overall knowledge of fisheries activities at the landing sites included in the study and the data collecting during that effort were updated as the study progressed. The initial baseline data collection and updated findings are included in the characterization of the landing sites presented in Appendices F through U and summarized in Sections 4.8 and 4.9.

2.4 Continuous Data Collection and Engagement with Supervisors

During the months from April 2019 through February 2020, the study team conducted regular visits to the landing sites in Regions 1 to 6. The objectives of these visits were to:

- Review completed data sheets from the regional and onboard supervisors;
- Meet with the supervisors to discuss data collected, trends, challenges, health and safety, and other information pertinent to the study;
- Engage with supervisors on lessons learned and areas of improvement;
- Collect photographs taken by regional and onboard supervisors;
- Collect GPS tracks and fishing waypoints from onboard supervisors;
- Replenish supplies, including new data sheets and batteries for cameras and GPS units;
- Check the status of equipment provided to the supervisors and replace any equipment found to be defective; and
- Provide volunteer stipends to supervisors based on the number of data sheets completed.

Two sets of data were collected from the supervisors (refer to Appendix D for a copy of the relevant data sheets):

1. The regional supervisors provided data that had been collected from vessels after landing at each of the six participating landing sites. For each landed vessel, data included fishing ground locations, total catch (including species and quantities), prices per species caught, and number of days spent at sea. Regional supervisors also collected biometric data (weights and lengths only[1]) of representative fish per landed species. The regional supervisors took photographs of fishes for which biometric data were recorded.
2. The onboard supervisors provided data that had been collected on their own vessels. These data included total catch per soaking (including species and quantities), GPS tracks showing the routes taken to fishing grounds, and GPS waypoints for the locations where fishing occurred. Onboard supervisors also measured and weighed the average-sized fish of each species caught per soaking and took photographs of their activities.

[1] No intrusive biometric sampling was performed as part of the study.

During the first of the continuous field visits starting in April 2019, the study team provided additional up-front training for the supervisors to reduce potential errors in the data collected. After the initial data collection field visits, and throughout the following year, supervisors in Regions 2 to 6 were visited either once or twice a month. Moreover, efforts were made to conduct visits to Region 1 at least once every month depending on the availability of the fisherfolk. However, visits to Region 1 were challenging to schedule and were ultimately based on the mutual availability of the study team and the supervisors. The study team was also in contact with all supervisors via telephone from all regions on a weekly basis to follow-up on their progress and to address any challenges encountered.

It should be noted that not all supervisors commenced data collection at the same time due to the selection and training process for supervisors being conducted sequentially over a period of 1 month at each of the landing sites. Moreover, timing and operational constraints led to smaller data pools collected by the onboard supervisors at the Rosignol (Region 5) and the Albion (Region 6) landing sites in the beginning months of the data collection efforts. Region 1 had the smallest data pools because the training and selection process was completed last in Region 1 due to the need to have tailored engagements with the village councils and Toshaos (Indigenous leaders), as well as the availability of the fisherfolk. Fuel shortages at Smith's Creek in Region 1 also curtailed fishing activities by the onboard supervisors and limited the data collected by the regional supervisor. For Waramuri in Region 1, the most recent data sets collected from the onboard supervisor were in November 2019. Efforts to collect data subsequently were curtailed due to the supervisor being at sea, and the closing of the community to outsiders due to the COVID-19 pandemic. A detailed schedule of the data collection periods analyzed in this report is presented in Appendix E.

2.5 Analysis and Reporting

Data that were collected biweekly and monthly were analyzed quarterly, beginning with the baseline data collection effort and continuing through February 2020. A summary of the key findings can be found in Section 4, while detailed findings by landing site, including data collected, trends, findings, and QA/QC results, can be found in Appendices F through U, with each appendix corresponding with a landing site.

It should be noted that the study team was unable to uplift the data sheets for the last 1 to 2 months in the final quarter of the study due to curtailment of all field work in February and March 2020 as a result of security and safety concerns pertaining to the General and Regional Elections and the COVID-19 pandemic. Accordingly, for most landing sites, the data pool for this study ends in February 2020. As of early May 2020, most of the study supervisors reported that they had collected data through March 2020 and that information will be presented to the study team if conditions allow. These supervisors also indicated that fishing activities had been continuing in spite of COVID-19 concerns; however, some supervisors stated that they had reduced their number of fishing trips, with only one onboard supervisor stopping his fishing activity altogether.

2.6 Quality Analysis/Quality Control

QA/QC exercises were conducted during the months of September–October 2019 and January–February 2020. The QA/QC exercises had the overall objective of identifying potential data deviations and standardizing data collection methods by the regional and onboard supervisors. Activities conducted as part of the QA/QC exercise included:

- Updating the landing site assessment, which was conducted as part of the initial baseline data collection effort to obtain information on fishing dynamics and significant events that are experienced at the sites. The landing site assessment was conducted based on interviews with fisherfolk who were present at the landing site when the study team visited.

- Conducting landing site assessments in parallel with the regional supervisors, including basic biometric measurements of landed fishes.
- Installing high-resolution (GoPro) cameras to vessels operated by selected onboard supervisors to conduct quality monitoring on how fishing activities are conducted. This aspect of the QA/QC exercise could only be conducted on vessels that spent less than 12 hours at sea due to constraints on camera battery life and memory storage.
- Taking biometric measurements of representative fishes caught by the onboard supervisors.

These exercises also included the video recording of fishing activities conducted on five onboard supervisors' boats at Region 3 (Windsor Forest and La Grange), Region 4 (Ogle), Region 5 (Bushlot), and Region 6 (Albion). The videos provided the study team with insight into specific fishing activities and provided a source for verifying the data collected.

The schedule of the QA/QC exercises is presented in Table E-2 in Appendix E.

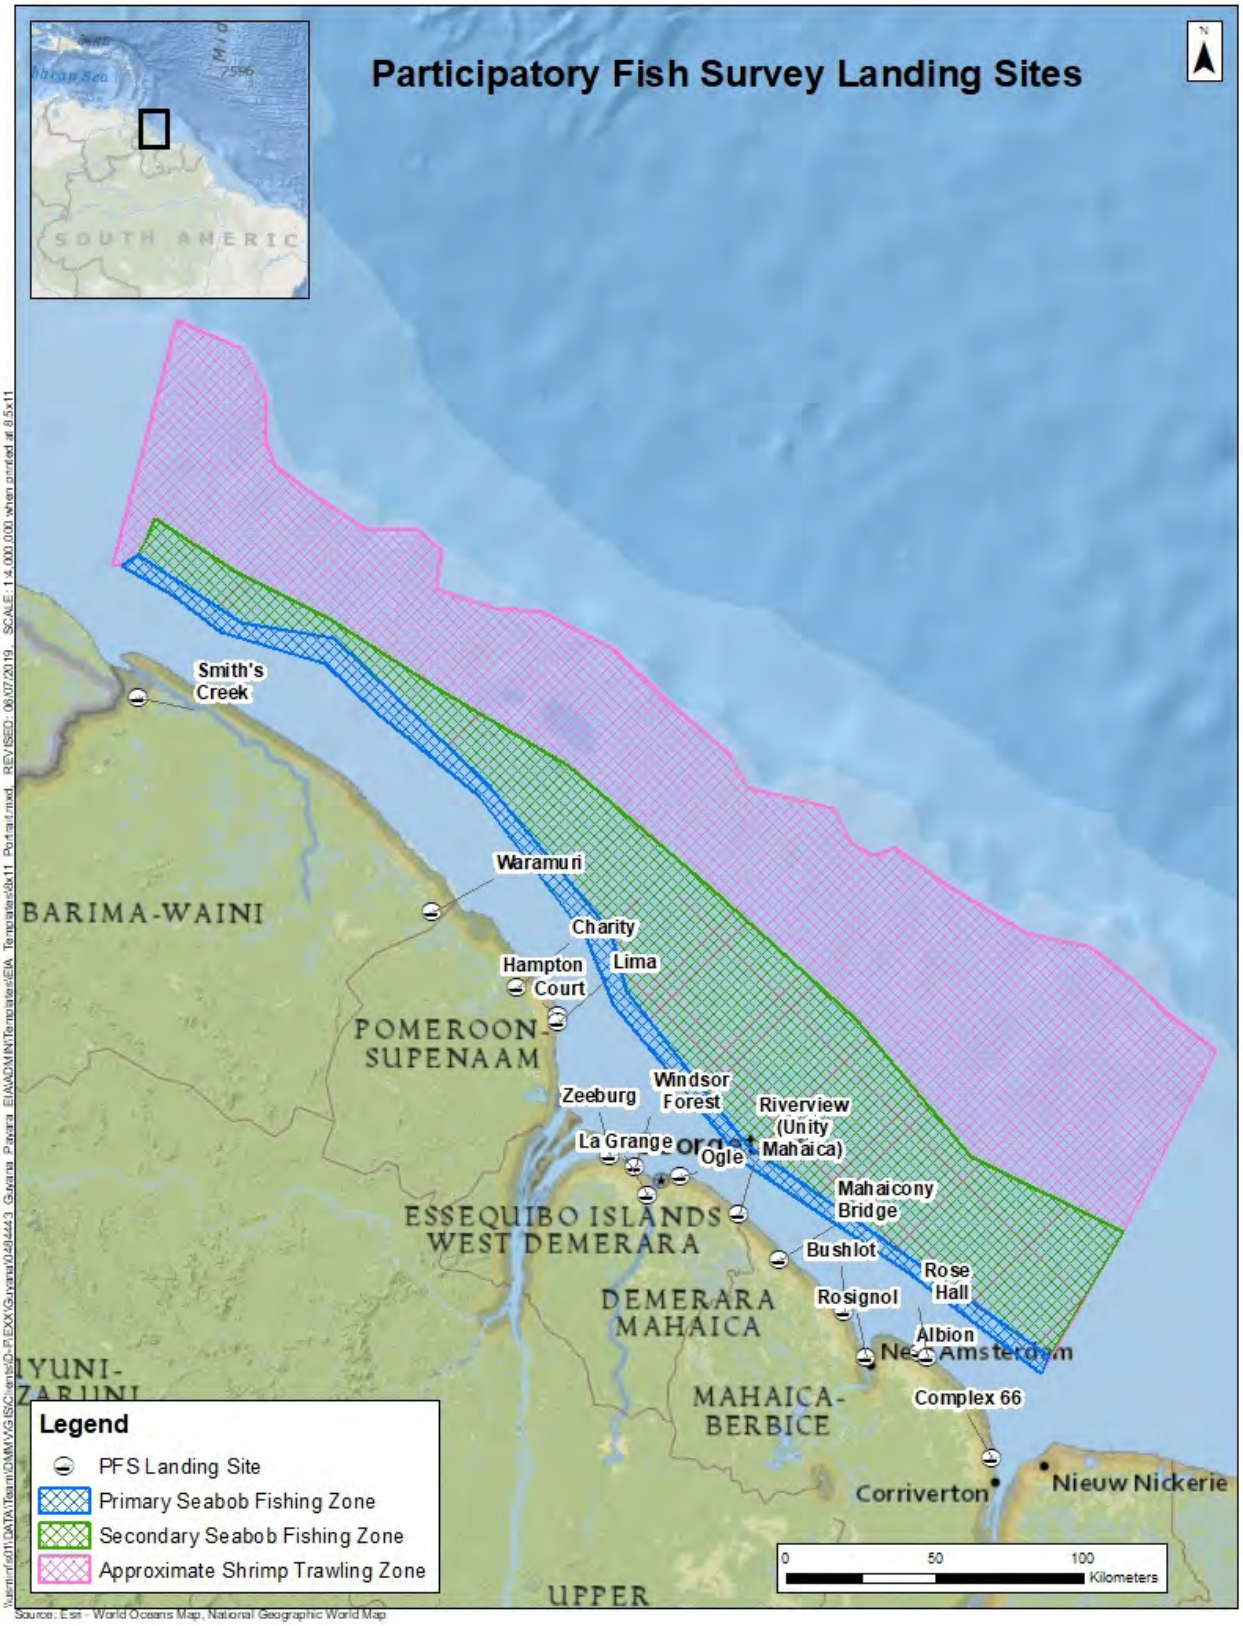

Figure 2-1: Locations of Landing Sites in Regions 1 to 6

3. OVERVIEW OF TOPICS

3.1 Marine Fisheries Species

For consistency throughout the report, Table 3-1 provides a table of commonly encountered species in Guyanese marine fisheries. See Appendix A for a full list and photos.

Table 3-1: Species Commonly Encountered in Guyanese Marine Fisheries

Species Name	Common Name
Micropogonias furnieri	basher, basha [a]
Cynoscion acoupa	grey snapper
Cynoscion virescens	trout
Cynoscion leiarchus	shine eye
Nebris microps	butterfish / butterhead
Carcharhinus limbatus	blacktip shark [b]
Carcharhinus porosus	san shark
Sphyrna lewini	hammerhead shark
Rhizoprionodon porosus	green shark
Chaetodipterus faber	spadefish / donkey fish
Sciades props	kukawri [c]
Batrachoides surinamensis	pacu
Macrodon ancylodon	bangamary [d]
Stellifer rastrifer	rockhead / white / rat mouth
Ctenosciaena gracilicirrhus	brickhead / rock head
Scomberomorus cavalla	kingfish
Scomberomorus brasiliensis	mackerel
Xiphopenaeus kroyeri	coarse shrimp / seabob
Cynoscion sp.	bangamary [d]
Odontognathus mucronatus	netly
Trichiurus lepturus	silverbelt
Lonchurus elegans	Chinese butterfish
Nematopalaemon schmitti	white belly shrimp
Achirus achirus and *Symphurus plagusia*	flounder
Centropomus undecimalis	snook
Farfantepenaeus sp. and *Litopenaeus* sp.	prawns [e]
Bagre bagre	sea catfish
Lobotes surinamensis	paggie / sea congo
Cathorops spixii	spring cuirass
Cathorops sp.	round head
Cathorops sp. and *Sciades* sp.	cuirass
Sciades parkeri	gillbacker
Megalops atlanticus	cuffum / tarpon

Species Name	Common Name
Genyatremus luteus	annafoke / old wife
Mugil cephalus	Suriname mullet
Anchoa spinifer	small herring
Elops saurus	long john
Pomatomus saltatrix	salmon
Harengula humeralis	shad
Brachyplatystoma vaillantii	lau
Sciades couma	cuma cuma / blinka
Cetengraulis edentulus	big eye herring
Echiophis punctifer	mud eel
Cynoscion similis	black tail basha
Pellona harroweri	mail boy
Isopisthus parvipinnis	flat banga
Mugil curema	quirman
Penaeus monodon	tiger shrimp
Prionotus punctatus	sea robin / flying fish
Katsuwonus pelamis	bonito / tuna
Anableps anableps	four eye
Rachycentron canadum	cabio
Physalia physalis	man O war
Callinectes sapidus	crab
Amphiarius rugispinis	twee
Bunocephalus sp.	banja man
Mugil sp.	cannapa
Selene vomer	chiny man / moonfish
Sphyraena guachancho	barracuda
Diapterus rhombeus	deep-sea fish
Pseudauchenipterus nodosus	sweet man
Oligoplites saliens	copper fish / thing bad
Epinephelus itajara	jewfish
Cynoscion sp.	bright eye
Caranax hippos	crevalle
Rhinoptera bonasus	sea Bat
Notarius grandicassis	Thomas
Trachinotus sp.	pompano
Hypanus sp. *Frontitrygon* sp.	stingray
Narcine bancroftii	shocking fish, electric ray
Menticirrhus americanus	crooker

[a] Basha and basher are used in different regions of Guyana and both refer to *Micropogonias furnieri*.
[b] All photos collected showed *C. limbatus*, but the data could have small numbers of other shark species included.

[c] Kukawri is used to refer to *Sciades proops* in this report, but the species is also known as kokwari and hard head cuirass in Guyana.
[d] Bangamary is used in Guyana to refer to both *Macrodon ancylodon* and *Cynoscion* sp.
[e] In Guyana, prawn is a blanket term used for both *Farfantepenaeus* sp. and *Litopenaeus* sp.

3.2 Measuring Hauls

Also, for consistency throughout this report, it is important to note that a variety of measurement units (baskets, tubs, buckets, and pounds) are used across landing sites in the various regions. During the engagements with fisherfolk and supervisors at each of the landing sites, the study team developed the following conversion units for estimating the volume of catch:

- One basket of fish is equivalent to 36.2 kilograms (80 pounds).
- One tub of fish is equivalent to 27.2 kilograms (60 pounds).
- One parcel of fish is equivalent to 4.5 kilograms (10 pounds).
- One bucket of shrimp is equivalent to 9.1 kilograms (20 pounds).

These measurement units are described throughout the report with the corresponding weight associated with that unit.

3.3 Characterization of Commercial Species

The artisanal fishing community assessed in this study targets several commercial species using specialized fishing gear and vessels. The species most prevalent in the study include bangamary, grey snapper (commonly referred to as snapper), and the two major shrimp species—white belly shrimp and coarse shrimp/seabob. Other frequently caught high-value and high-demand species include trout, gillbacker, and cuirass. Fisherfolk have also reported catching jewfish and shark, which are both endangered, rare, and threatened species. The following sections provide a brief description of each of these species as recorded historically and during the study. The mature lengths of the species were based on data sourced from Fish Base (2020), which is the largest global species database.

3.3.1 Bangamary

When mature, bangamary has an average standard length of 32 centimeters (12.6 inches) and some fish can grow to lengths exceeding 40 centimeters (15.7 inches). As juveniles, bangamary live in mud or in sandy mud bottoms. Bangamary feed mainly on shrimp and small fishes. They are commonly found along the northern coast of South America. Bangamary has a known life expectancy of up to 6 years (Haimovici and Cardoso 2011).

In Guyana's artisanal fishing industry, mature bangamary are targeted with drift seines with mesh sizes of 7 centimeters (2.75 inches) and the juveniles are caught with Chinese seines. Fisherfolk in Guyana refer to bangamary as "the fish who bites twice" in reference to the fish biting lines and to the frequent cuts to their hands from handling the fish when caught.

3.3.2 Snapper

Snapper are bottom-oriented fish that prefer mouths of rivers with muddy and sandy bottoms. During the day, snapper hide in crevices, but come out to hunt crustaceans and smaller fishes at night (Rodrigues et al. 2008). These fishes tend to form schools. Juveniles live primarily in the mangroves, a behavior that helps to protect them from predators. Mature snapper have been recorded as growing up to 110 centimeters (43.3 inches) in length.

In Guyana, snapper is considered a high-value species. In recent years, the markets and prices for the swim bladders of snapper, referred to locally as *glue*, have significantly expanded. Although snapper was

already a highly targeted species, high demand and prices for glue have incentivized the increased targeting of this fish species. Fisherfolk targeting snapper use drift seines with mesh sizes of 18 centimeters (7 inches) and vessels capable of spending extended periods at sea, typically up to 2 weeks.

3.3.3 Shrimp

Two major shrimp species occur in Guyana—white belly shrimp and seabob, the latter of which is frequently referred to as coarse shrimp. Both species occur in brackish waters in the benthic zone, where they feed on plant matter along with dead and decaying animal matter. White belly is the smaller of the two species, which at maturity achieves a maximum length of approximately 8 centimeters (3.1 inches). The larger species, seabob, can grow up to 11 centimeters (4.3 inches).

Shrimp spawn mainly during two seasons in Guyana: January to April and June to July (Periera 2017). In Guyana, fisherfolk use Chinese seines to target these shrimps. An invasive shrimp species, the tiger shrimp, has recently become established in Guyana and is sometimes caught by local fisherfolk.

3.3.4 Trout

Trout live in muddy sandy bottoms in coastal waters near the mouths of rivers. Juveniles live in estuaries and mangroves. Like snapper, adults stay in deep water during the day and come out to feed during the night. Their diet is mainly comprised of small fishes and crustaceans. Mature trout can achieve lengths of 90 centimeters (35.4 inches).

In Guyana, trout is considered a medium- to high-value species. Like snapper, markets and prices for its glue have significantly increased in recent years. Trout is typically the second or third most abundant species caught using drift seines with mesh sizes of 7 to 18 centimeters (2.5 to 7 inches), which are designed to target bangamary and snapper.

3.3.5 Cuirass

Cuirass refers to catfishes from the family Ariidae and may either be part of the genus *Cathorops* or *Sciades*. Several species are referred to as cuirass in Guyana including spring cuirass, flat head cuirass, hard head cuirass (also called kokwari), and mud cuirass. Cuirass are characterized by having very hard cranial bones and live in turbid estuaries and mangrove-lined lagoons with shallow soft bottoms. They feed on numerous pelagic organisms found in mangroves, including small crabs and fishes. Spawning season occurs from September to January and females incubate eggs in their mouths for 20 to 50 days. Mature fishes have lengths of 40 to 55 centimeters (15.7 to 21.6 inches), but some species can grow to a maximum of 94.5 centimeters (37.2 inches).

In Guyana, cuirass are typically low- to medium-value fishes in the marketplace. The swim bladders from cuirass are also sold, but this is not as prevalent or as high-value as the glue from snapper and trout. They are not the target species of any fishing practices, but are widely caught nonetheless by virtually all seine types, and are therefore one of the main commercial species. Cuirass is mainly sold in local markets.

3.3.6 Jewfish

The jewfish is commonly referred to as the Atlantic goliath grouper and is classified as a critically endangered species by the International Union for Conservation of Nature (IUCN). Jewfish live in environments with corals and in muddy bottoms of the seafloor and are also known to occupy shipwrecks. Jewfish occupy a range extending from the Florida coast to the Brazilian coast, inhabiting the entire Caribbean Sea. They typically spawn in estuaries from July to August. Jewfish feed on small turtles,

fishes, and crustaceans. Jewfish is one of the largest bony fish species and can reach a maximum length of 240 centimeters (94.5 inches) and weigh over 272 kilograms (600 pounds).

As part of this study, jewfish were recorded in Regions 1, 2, and 6. It was not targeted by these fisherfolk, but was sold on commercial markets when caught. Additional research is required to determine the prevalence of this species in Guyana's nearshore coastal waters.

3.3.7 Gillbacker

The gillbacker is another species of catfish popular in Guyana. They are commonly found in muddy and sandy bottoms, spawning near estuaries during the rainy seasons, and are distributed along the coast of South America. Gillbacker mature at around 46 centimeters (18.1 inches), but can achieve maximum lengths of 190 centimeters (74.8 inches) and weights of 50 kilograms (110 pounds).

Gillbacker was previously one of the highest-value fish species on local and export markets. In 2018, the United States Department of Agriculture (USDA) banned the import of catfishes and catfish products from Guyana because food safety inspection systems were not equivalent to U.S. inspection systems. At peak prices before the ban, it retailed for $2,200 Guyanese dollars (GYD) per kilogram ($10.5 United States dollars [USD] per kilogram). The loss of this export market significantly reduced the prices of gillbacker on local markets and retail prices are now less than half of the previous peak prices.

3.3.8 Shark

Several species of sharks occur in Guyana, but identification of sharks caught by artisanal fisherfolk is extremely challenging due to the similarities in many coastal sharks' appearance, the tendency to bring sharks to market without heads (which eliminates several diagnostic features that could be used to identify specimens), and a tendency among fisherfolk to simply group all sharks into a single category. Despite these challenges, the shark fishery in Guyana is known to target a diverse group of species. The most common shark species caught for commercial sale by artisanal fisherfolk are often reported to be blacktip shark, tiger shark, bull shark, and hammerhead shark, but a genetic study conducted in 2017 documented 13 species of sharks in fish markets based on DNA analysis. Over 70 percent of the total sample diversity was represented by five species: Brazilian sharpnose shark (*Rhizoprionodon llandii)*-18.9 percent), smalltail shark (*Carcharhinus porosus)*-17 percent, scalloped hammerhead (*Sphyrna lewini*)-17.4 percent, great hammerhead (*Sphyrna mokarran*)-10.6 percent, and blacktip shark (*Carcharinus limbatus*)-8.3 percent (Kolmann et al. 2017). This study suggests that the Guyanese shark fishery captures a more diverse group of small requiem sharks than once thought.

Sharks are generally viviparous and have a relatively slow rate of reproduction compared to other fishes that lay thousands of eggs. Age and size at maturity vary by species, but the species that comprised the bulk of the catch in the 2017 study mature at between 2 years of age (sharpnose sharks) and 20 years of age (great hammerhead sharks). Sharpnose and smalltail sharks are relatively small sharks, maturing at around 1 meter in length, blacktip sharks are slightly larger with a maximum size of about 2 meters, but great hammerheads can reach well over 3 meters in length.

Regardless of species, the Guyana shark fishery tends to capture juvenile sharks. Sharks are relatively low-value on local commercial markets. As a result, sharks are not targeted species by artisanal fisherfolk, especially the nurse shark and whale shark, which are typically released if caught.

3.4 Seine Characterization

Several types of fishing methods and gear are used by artisanal fisherfolk for marine fishing, including pin seines, Chinese seine (also referred to as fyke nets), Cadell lines (also referred to as demersal long lines), and drift seines. The nets are manufactured in various mesh sizes and the Cadell lines may have

different hook sizes depending on the species and size of fish that are targeted in a specific location. Data for each of these fishing types were captured by the study's regional and onboard supervisors and are described below.

3.4.1 Pin Seine

Pin seines, also referred to as beach seines, are set on the mudflats a few meters offshore. In this method of fishing, short poles are stuck in the ground, and the seines are attached to the poles. Similar to the Chinese seine fishing method, tidal currents push fishes into the seine. Seines are set and left out during high tides and fisherfolk return to collect their catch during low tides. Fisherfolk access their seines by traveling via modified surfboards (*catamarang*) or small boats into which the catch is loaded and pushed to shore. Figure 3-1 shows the poles to which pin seines are attached. This type of fishing does not target any specific marine species, and may capture several nearshore species, including white belly shrimp, coarse shrimp, bangamary, and cuirass.

Figure 3-1: Pin Seine at Rose Hall Beach

3.4.2 Chinese Seine (Fyke Net)

Chinese seines are typically used relatively close to shore, approximately 10 meters (32.75 feet) from the shoreline. Chinese seine mesh can range from 1.27 to 10.16 centimeters (0.5 to 4 inches). These seines are normally attached to poles, commonly referred to as "pens," that are placed perpendicular to the tidal current. Normally, a series of seines are attached to pens. Within the poles, the seine is an open-faced square that tapers at one end into a funnel-like projection. Fishes are forced into the seines by the tidal currents. Figure 3-2 shows the shape a Chinese seine takes within the pen. The same person may fish one or more pens based on their needs and accessibility.

Fisherfolk travel to and from shore via channels to set their seines; the channels are accessible mainly at high tide. The fisherfolk using this method spend about 3 to 4 hours at sea, mainly to repair seines, collect the catch, and re-set the seines. Fisherfolk using Chinese seines normally target shrimp, including white belly shrimp and seabob/coarse shrimp. Catch also typically includes cuirass, sea catfish, small

bangamary, and silverbelt; these species are often captured in Chinese seines due to the relatively small mesh sizes used in this type of gear.

Figure 3-2: Chinese Seine Pen Poles Outside the Ogle Shore

3.4.3 Cadell Line (Demersal Longline)

Cadell line fishing is performed with a line of baited hooks anchored to the sea floor (see Figure 3-3 showing the nets). Cadell lines may be more than 2 kilometers (1.24 miles) long and have close to 100 hooks. Bait includes beef, small herrings, and mullet fishes. Fisherfolk using this method may venture as far as 40 kilometers (24.9 miles) offshore. This type of fishing does not target specific species, but some selectivity is possible based on the size of hook used. In general, catch includes sea catfish, gillbacker, snapper, trout, kokwari, and bangamary. This method of fishing has little-to-no bycatch and few fish are discarded regardless of species.

Figure 3-3: Cadell (Demersal Long Line) Nets Used for Fishing Activity

3.4.4 Drift Seine (Gillnets)

Drift seines are the most commonly used gear among artisanal fisherfolk in Guyana. They are modified gillnets and typically are large and circular with floats at the top and weights attached to the bottom. Drift seines are characterized by their mesh sizes. The size of the mesh on a drift seine can be designed to target specific species. For example, seines with mesh sizes of 7 centimeters (2.75 inches) typically target bangamary, while seines with mesh sizes of 11.4 and 17.8 centimeters (4.5 and 7 inches) target snapper. Some drift seines may have mesh as large as 20.3 to 22.9 centimeters (8 to 9 inches) to target larger similar species such as gillbacker and snapper. Drift seines are deployed in open waters about 20 kilometers (12.4 miles) from shore. Fisherfolk using this method may take daily fishing trips spending approximately 8 hours at sea (see Figure 3-4 for an example of the boats used); however, drift seining vessels have been known to be at sea for extended periods of up to 2 weeks.

Figure 3-4: Drift Seines at the Charity Landing Site

3.5 Vessel Characterization

In Guyana, most artisanal fishing vessels are categorized as an inboard cruiser or outboard cruiser based on size and the position of the engine. However, fishing vessels that do not require engine power are also used by some artisanal fisherfolk. Regional and onboard supervisors collected data on hauls and fishing practices for all types of vessels used in artisanal fishing.

3.5.1 Vessels Used for Pin Seine Fishing

Vessels used for pin seine fishing are the smallest vessels used by artisanal fisherfolk in Guyana. These vessels are modified surfboards (*catamarangs*) that are approximately 2 meters long with a wooden box affixed near the center of the board and are not powered by engines (Figure 3-5). Pin seines are set on the mudflats a few meters off the shore. These vessels are used by a single crewmember who pushes out to the seines during low tide to collect the catch. These vessels can carry up to 90 kilograms (200 pounds) of catch from the seines to shore. Pin seine fishing is prevalent across the coast because vessels can be launched directly from the mudflats and are relatively low-cost in comparison to other fishing vessels.

Figure 3-5: Catamarang used for Pin Seine Fishing at the La Bonne Intention Landing Site

3.5.2 Sailboats

Sailboats were popularly used by artisanal fisherfolk in Guyana about 15 years ago and at that time, the Better Hope landing site was the largest landing site for these vessels. However, their popularity drastically declined as the use of engines became widespread in artisanal fishing. Sailboats are typically approximately 8 meters long, 2 meters wide, and 1 meter high (Figure 3-6). Sailboats use drift seines with mesh sizes of 7 to 18 centimeters (3 to 7 inches). These vessels depend on the wind to travel to their fishing grounds approximately 10 kilometers offshore at depths of 8 meters. However, some sailboats also have 15 horsepower (hp) outboard engines that are used when the wind is not sufficient to power the vessel or the direction of the wind is not suitable for fishing activities. These vessels have crews of one to two persons who spend up to 24 hours at sea. These vessels have haul capacities of approximately 450 kilograms (1,000 pounds). Currently, only the Bushlot landing site in Region 5 has a large number of sailboats in Guyana.

Figure 3-6: Sailboat at Bushlot Landing Site Region 5

3.5.3 Outboard Cruisers Used for Chinese Seine Fishing

Artisanal vessels using Chinese seines are categorized as outboard cruisers and are among the smaller vessels in Guyana (Figure 3-7). These vessels are approximately 8 meters long, 1.5 meters wide, and 1 meter high. Generally, 15 hp engines are used by these vessels and placed at the rear of the vessel. These vessels travel to fishing grounds approximately 5 kilometers offshore, and 9 meters deep. They have crews of one to three persons who spend from 6 to 12 hours at sea. These vessels have haul capacities of approximately 500 kilograms (1,100 pounds) and catch is stored in baskets, buckets, and coolers while at sea.

The major landing sites for Chinese seine fishing are: Lima and Hampton Court landing sites in Region 2; Zeeburg, Windsor Forest, and Goed Fourtin landing sites in Region 3; Ogle landing site in Region 4; and Rosignol landing site in Region 5.

Figure 3-7: Chinese Seine Vessels at Windsor Forest

3.5.4 Outboard Cruisers Used for Drift Seine (Bangamary Seines) Fishing

Outboard cruisers that use 7-centimeter (2.75-inch) mesh size drift seines are commonly referred to as bangamary seines, as they primarily target this species (Figure 3-8). They are approximately 11.5 meters long, 2 meters wide, and 1 meter deep. Generally, these vessels use 40 to 48 hp engines that are positioned at the rear of the vessel (Figure 3-8). These vessels travel approximately 30 kilometers offshore and fish at depths of 20 meters. These vessels have crews of two to four persons who spend at least 12 hours, but no more than 3 days at sea. They have a haul capacity of up to 2,045 kilograms (4,500 pounds) and they typically utilize iceboxes for storage of catch while at sea.

The major landing sites for these vessels are located in Good Hope, Enmore, Hope, Bee Hive, and Riverview (Unity, Mahaica) in Region 4; Mahaicony Bridge, Abary, and D'Edwards in Region 5; and Albion in Region 6.

Figure 3-8: Outboard Cruisers Using Drift Seines (Bangamary Seines) at Riverview (Unity Mahaica)

3.5.5 Outboard Cruisers Used for Drift Seine (Snapper Seine) Fishing

Outboard cruisers that use 18-centimeter (7-inch) mesh size drift seines are among the largest vessels used by artisanal fisherfolk in Guyana, and primarily target snapper (Figure 3-9). The vessels are generally 14 meters long, 2.2 meters wide, and 2 meters high. These vessels may have up to two outboard engines positioned at the rear of the vessel. These engines are 48 to 60 hp and travel to fishing grounds approximately 40 kilometers offshore at depths of 37 meters. The vessels have crews of four to seven persons and spend 1 to 3 weeks at sea. These vessels have haul capacities of approximately 4,545 kilograms (10,000 pounds).

Major landing sites for these vessels include Charity and Hampton Court in Region 2; Parika in Region 3; Meadow Bank, Montrose, Hope, and Riverview (Unity, Mahaica) in Region 4; Mahaicony, Rosignol, and D'Edwards in Region 6; and Adventure, Number 65, and Complex 66 in Region 6.

Figure 3-9: Outboard Cruiser Using a Drift Seine (Snapper Seine) at Complex 66

3.5.6 Inboard Cruisers

Inboard cruisers are the largest artisanal fishing vessels (Figure 3-10). Engines for these vessels can exceed 100 hp and are normally built into the boat, hence their name. They are 16 meters long, 4 meters wide, and 3.5 meters high. These vessels use drift seines with mesh sizes of 19 centimeters (7.5 inches) and generally target snapper. These vessels have crews of four to seven persons who spend approximately 18 days at sea. The holds of these vessels are designed to store large quantities of ice, which is used to preserve catch during extended periods at sea. Their fishing grounds are usually 40 kilometers offshore at depths of 70 meters. These vessels have haul capacities of 18,000 kilograms (39,600 pounds). The major landing sites where these types of vessels are found are Charity (Region 2) and Meadow Bank (Region 4).

Figure 3-10: Inboard Cruiser at the Charity Landing Site Region 2

4. KEY FINDINGS

The artisanal fisherfolk from whom the regional and onboard supervisors collected data used a variety of fishing practices. These varied fishing methods produced significant differences in the catch composition and total haul volumes. These differences are attributed to a variety of factors including, but not limited to:

- Type of fishing gear used (seine type and mesh size)
- Type of vessel used and length at sea
- Target species that are considered commercially viable at each landing site
- Seasons in which fishing activities occur

4.1 Gear Type and Target Species

As demonstrated in the data collected by both the onboard and regional supervisors, specific types of fishing gear are used to reliably target specific species of fishes, even though fishing may occur in different ecological zones and different locations across Guyana's coastal regions. Moreover, seines with larger mesh sizes catch larger fishes, most of which have reached sexual maturity because smaller species and smaller fishes are more likely to escape capture. Seines with larger mesh sizes typically have less species diversity per haul. **As a result, the type of fishing gear used is a good indicator of the species composition of the hauls as well as the most abundant species caught**. The following information was gathered on typical species caught for each seine type:

- Drift seines with mesh sizes of 10 to 20 centimeters (4 to 8 inches) were used at the Charity landing site to target snapper. These seines are commonly referred to as "snapper seines" by fisherfolk. As the target species, snapper accounted for 60 percent of the total recorded haul by weight at this landing site. The second most abundant species caught using this seine type was trout. Similar catch compositions were observed in hauls from onboard supervisors at the Rosignol (Region 5) and Complex 66 (Region 6) landing sites where drift seines with mesh sizes of 19 centimeters (7.5 inches) were also used to target snapper. The onboard supervisor from the Hampton Court

landing site (Region 2) used drift seines with mesh sizes of 20 centimeters (8 inches) to target large species like snapper and gillbacker.

- Drift seines with mesh sizes of 6.5 to 7 centimeters (2.5 to 2.75 inches) were the principal types of gear used at landing sites in Riverview (Region 4) and Mahaicony Bridge (Region 5) to target bangamary. These seines are commonly referred to as “bangamary seines” by fisherfolk. The target species bangamary accounted for 36 and 76 percent of the total hauls at Riverview and Mahaicony Bridge landing sites, respectively. The second and third most abundant species caught using the bangamary seines were butterfish and trout. Similar catch composition of the three most abundant species caught was observed in the data collected by the onboard supervisors at landing sites in Riverview and Albion (Region 6) where bangamary seines were also used. Although these three species were the most abundant, the species diversity of hauls from bangamary seines was relatively high.
- Drift seines with mesh sizes of 2.5, 5, 7.5, 10, and 12.7 centimeters (1, 2, 3, 4, and 5 inches) were used by the onboard supervisor of Vessel A at the Smith’s Creek landing site (Region 1). The 2.5-, 5-, and 7.5-centimeter (1-, 2-, and 3-inch) mesh size seines were used to target sea bats. Sea bats accounted for 36 percent of the onboard supervisor’s haul. Typically, the onboard supervisor used drift seines with a variety of mesh sizes to fish, but opted to target sea bats during the study because of a valuable export market to Venezuela. Based on the data collected by the regional supervisor, sea bats were considered a commercial species at the Smith’s Creek landing site but not reported by other fisherfolk in great abundance.
- Chinese seines have smaller mesh sizes and are used to target shrimp species. At the Zeeburg landing site (Region 3), Chinese seines with mesh sizes of 2.5 to 10 centimeters (1 to 4 inches) yielded hauls of which white belly shrimp comprised approximately 85 percent. At landing sites in Lima (Region 2) and Ogle (Region 4), Chinese seines also yielded white belly shrimp and coarse shrimp as the most abundant species caught. The onboard supervisor at the Windsor Forest landing site (Region 3) also used Chinese seines as the principal gear type to target white belly shrimp, but bangamary was the most abundant species caught. The majority of fishes caught using Chinese seines had not achieved sexual maturity.
- Pin seines also have smaller mesh sizes than drift seines, and unlike Chinese seines do not have a specific target species. However, at the Rose Hall landing site (Region 6), the most abundant species caught were white belly shrimp and coarse shrimp. Shrimps were likely the most abundant species caught because of the relatively small mesh sizes of the seine. Although pin seines were used occasionally by the onboard supervisor at Lima (Region 2), the supervisor did not disaggregate the hauls on the fishing trip based on the different gear used, so further analysis was not possible.
- Cadell lines were used to target sea catfish by the onboard supervisors at Waramuri (Region 1) and La Grange (Region 3). More than 75 percent of the hauls from these two landing sites were sea catfish. In addition, sea catfish was the second most abundant species caught by the onboard supervisor at the Windsor Forest landing site (Region 3) using Cadell lines as a secondary gear type.

A summary of these key findings at each landing site is presented in Table 4-1.

Table 4-1: Summary of Key Findings at Landing Sites

Landing Site	Gear Type	Target Species	Percentage of Haul by Weight
Charity	Drift seines, 10-20 cm	Snapper	60%
Rosignol, Complex 66	Drift seines, 19 cm	Snapper (see above)	50-65%
Hampton Court	Drift seines, 20 cm	Gillbacker (pictured) and Snapper (see above)	56% (Gillbacker) 40% Snapper
Riverview, Mahaicony Bridge, Albion	Drift seines, 6.5-7 cm (referred to as bangamary seines)	Bangamary	36-76%
Smith's Creek	Drift seines, 2.5, 5, & 7.5 cm	Sea Bats	36%
Zeeburg	Chinese seines, 2.5-10 cm	White Belly Shrimp	85%
Ogle	Chinese seines, 2.5-10 cm	Coarse Shrimp	71%
Lima, Windsor Forest	Chinese seines, 2.5-10 cm	White Belly Shrimp (see above)	11-30%

Landing Site	Gear Type	Target Species	Percentage of Haul by Weight
Waramuri, La Grange	Cadell lines	Sea Catfish	>75%

cm = centimeters

Unlike the other landing sites from which regional supervisors collected data, there was no specialization of gear type used by the fisherfolk at the Smith's Creek landing site (Region 1). Instead, fisherfolk used a variety of seines and mesh sizes including drift seines with mesh sizes ranging from 2.5 to 18 centimeters (1 to 7 inches), Cadell lines, and pin seines. As a result, the species most frequently caught by fisherfolk in Smith's Creek were cuirass, which can be caught in relative abundance with any of the fishing gear used, particularly in the estuaries where most fishing activities occur. Snook was also frequently caught and, like cuirass, may be caught with any of the seine types. The other six species most frequently caught included bangamary, butterfish, trout, snapper, snook, and sea catfish, which are the target species of bangamary seines, snapper seines, and Cadell lines. Similarly, the onboard supervisor of Vessel B at the Smith's Creek landing site used drift seines with a variety of mesh sizes including 2.5, 5, 7.5, 10, and 12.7 centimeters (1, 2, 3, 4, and 5 inches). The most abundant species caught was snapper, which indicates that snapper seines were used frequently during the study. Other abundant species caught included cuirass, snook, and paggie, which can be caught by a variety of gear types.

Fishing grounds may also influence the abundance with which target species are caught relative to other species in the haul. The onboard supervisor from the Bushlot landing site (Region 5) used drift seines with mesh sizes of 11 centimeters (4.5 inches), 13 centimeters (5 inches), and 18 centimeters (7 inches), which are generally intended to target larger species like snapper and trout. However, the species most frequently caught was cuirass, which can be caught with a variety of seine types. Snapper and trout were the second and fifth most abundant species caught, respectively. In contrast to other onboard supervisors targeting snapper and trout, the Bushlot onboard supervisor stayed relatively close to the shore and had shorter fishing trips. The importance of these factors in achieving hauls in which the target species are also the most abundant species caught is discussed further below.

4.2 Effort and Haul

A significant determinant of haul volumes is the type of vessel used. Vessel type directly determines haul volumes because larger vessels have greater haul capacities. For example the largest artisanal vessel inboard cruisers have haul capacities of 18,000 kilograms (39,683 pounds). By contrast, the catamarangs used by pin seine fisherfolk only have a haul capacity of 90 kilograms (198 pounds). The vessel haul capacities also influence the level of effort because vessels that have greater haul capacities can spend longer periods at sea per fishing trip. In some instances, fishing practices can further create opportunities for maximizing the vessel's haul capacity on each fishing trip. For example, fisherfolk at the Charity landing site gut fishes at sea as a preservation method, but also as a means of reducing haul weights. Lower haul weights over time create the opportunity for increased soaking of the seine and allow for optimal use of the vessel's haul capacity. As shown on Figure 4-1, the size of the haul varies by region, and fisherfolk from each region (with the exception of Region 1) typically used one type of vessel predominantly.

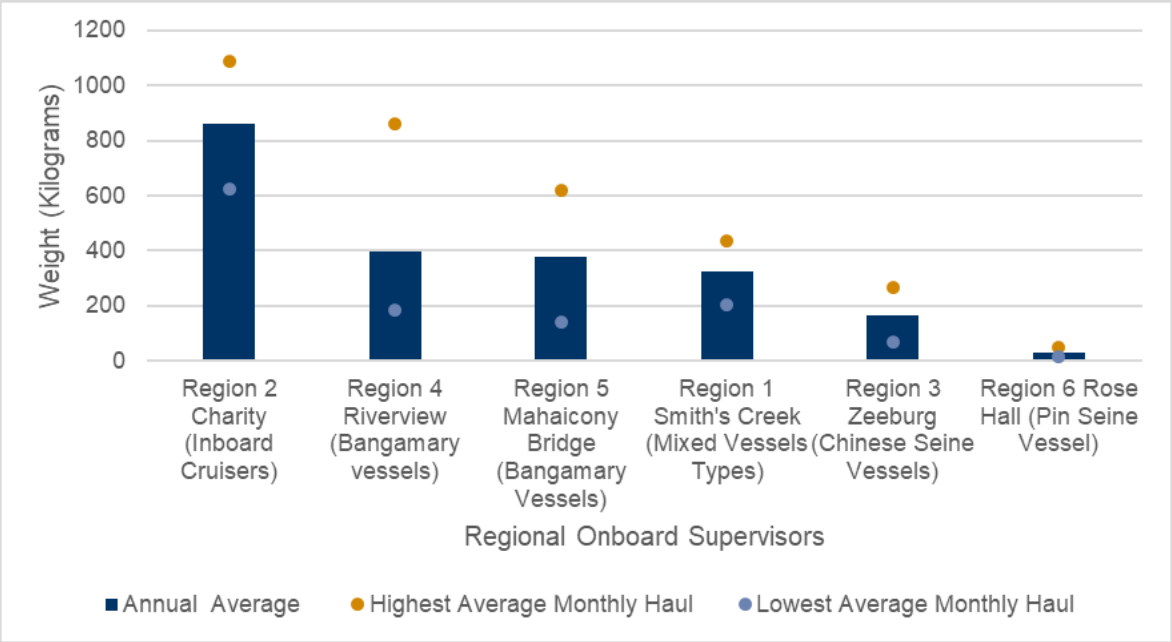

Figure 4-1: Haul Volumes at Landing Sites with Regional Supervisors

Vessel type also influenced the effort expended per fishing trip. Typically, larger vessels are capable of spending longer periods at sea fishing and traveling farther away from their landing sites to access preferred fishing grounds. The inboard cruisers at the Charity landing site (Region 2) expend the greatest effort of all artisanal vessel types. These vessels typically spend upwards of 2 weeks at sea per fishing trip due to larger capacities that can accommodate crew, maintain a stock of supplies, and store ice used to preserve the haul. These fisherfolk also prefer to fish in the Waini and Barima rivers in Region 1 and in doing so, travel farther away to fish.

As seen on Figure 4-2, the greatest average effort made during the study was expended by inboard cruisers at Charity (Region 2). By contrast, the lowest effort was expended by fisherfolk at Zeeburg (Region 3) and Rose Hall (Region 6), where the smallest artisanal vessels were used for activities targeting shrimp. Both Chinese seine and pin seine fishing are tidal activities. Fishing grounds are typically in fixed locations offshore, namely the “pens” used for Chinese seines and the poles erected for attaching pin seines. As a result, effort expended per fishing trip was relatively stable throughout the study period. At Zeeburg and Rose Hall landing sites, the average effort expended per fishing trip during the study was 7 hours and 12 hours, respectively.

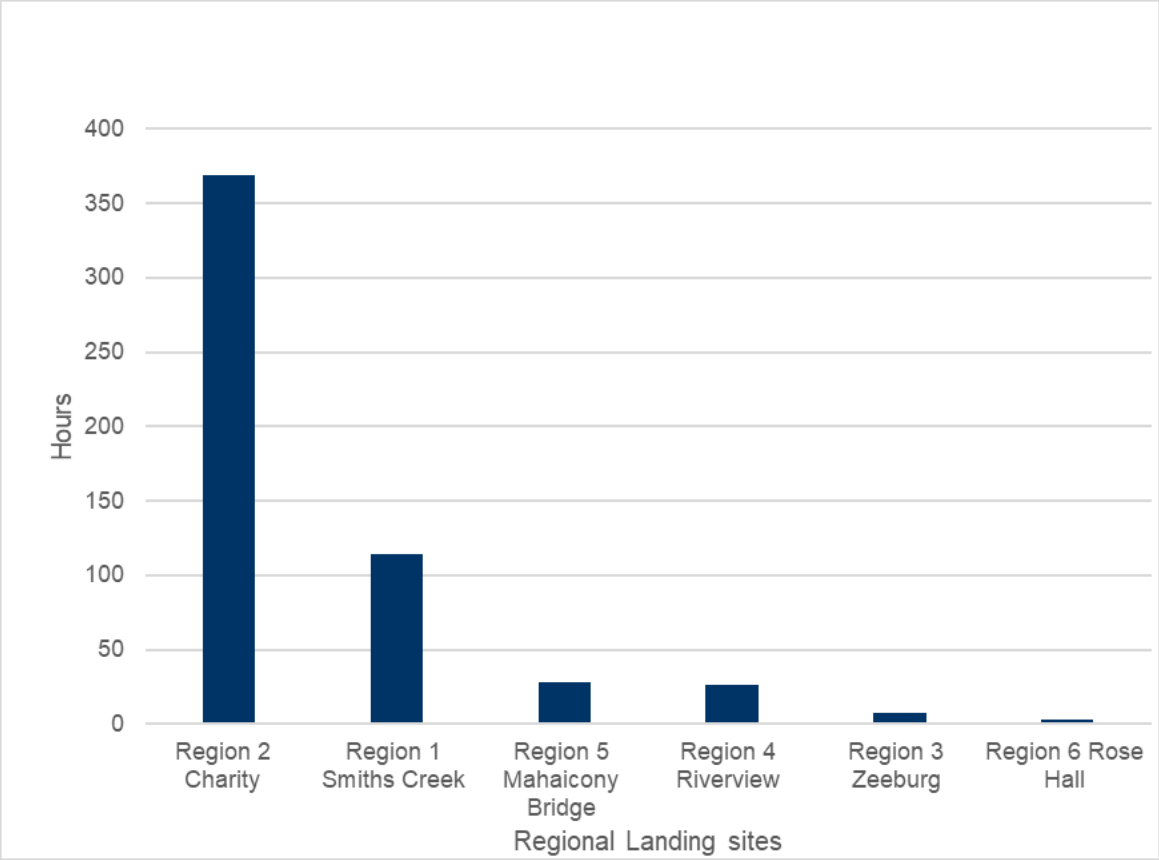

Figure 4-2: Average Fishing Effort per Month at Landing Sites with Regional Supervisors

Larger vessels have significantly higher expenses per fishing trip than smaller vessels. Typically, fisherfolk at the Charity landing site expend approximately $540,000 GYD ($2,583 USD) on fuel, ice, and rations per trip. By contrast, almost no expenses are associated with the use of catamarangs for fishing activities. Fuel required to conduct fishing trips using Chinese seines costs approximately $5,000 GYD ($24 USD) per trip. However, as observed at Smith's Creek and Morahwanna landing sites, external factors increased fuel prices during the study and thereby also increased the costs associated with conducting a fishing trip.

Generally, larger predatory fishes like snapper and trout require greater effort to catch. As a result, fisherfolk targeting these species tend to spend prolonged periods at sea. For example, fisherfolk targeting snapper at the Charity landing site typically have fishing trips lasting more than 2 weeks, whereas fisherfolk targeting smaller species, such as shrimp, expend lower effort to achieve optimum hauls. As such, greater effort per fishing trip was also observed from onboard supervisors at Hampton Court (Region 2), Rosignol (Region 5), and Complex 66 (Region 6) who also target larger species like snapper, trout, and gillbacker.

Level of effort was also observed to be influenced by the distances that fisherfolk had to travel to access their preferred fishing grounds. For example, fisherfolk at Smith's Creek and Morahwanna (Region 1), Riverview (Region 4), and Mahaicony Bridge (Region 5) have similar vessel types. However, preferred fishing grounds are located farther from the landing site for fisherfolk from Smith's Creek/Morahwanna and as a result, greater effort is required to access these fishing grounds. In addition, greater effort was likely expended at Smith's Creek and Morahwanna as a result of the high fuel prices which encouraged

fisherfolk to spend longer periods at sea as a strategy to maximize fuel consumption efficiency. However, it is likely that the duration of the fishing trips was ultimately limited by the haul capacities of the vessels. Given the haul capacities of the vessels used, the annual average haul and the maximum total haul at Smith's Creek and Morahwanna was lower than Riverview and Mahaicony Bridge.

Similarly, based on data collected by the onboard supervisors, fishing practices were a major factor in determining the effort expended per fishing trip. Consequently, the onboard supervisors from Hampton Court (Region 2), Rosignol (Region 5), Bushlot (Region 5), and Complex 66 (Region 6), who all used seines with larger mesh sizes to target larger fishes like snapper and trout, consistently expended greater effort per month. Moreover, the vessels used by the onboard supervisors from Hampton Court, Rosignol, and Complex 66 had greater haul capacities than any of the vessels used by the other onboard supervisors and therefore, longer periods could be spent at sea in pursuit of the target species. Only these three onboard supervisors expended more than 200 hours monthly on average for fishing activities. The onboard supervisor from Bushlot had a smaller vessel and did not spend prolonged periods at sea per fishing trip, but completed more fishing trips than the other three supervisors.

The second highest average monthly effort was expended by the onboard supervisors from Riverview (Region 4) and Albion (Region 6) who used bangamary seines for fishing. The average effort expended by these supervisors was comparable, with 165 hours and 167 hours monthly being expended on average at Riverview and Albion, respectively. The lowest effort was expended by the onboard supervisors from Lima (Region 2) and Ogle (Region 4) who used Chinese seines for fishing. Moreover, although the onboard supervisors from Waramuri (Region 1) and La Grange (Region 3) both used Cadell lines, monthly effort by the Region 1 supervisor was significantly higher than by the Region 3 supervisor. This was likely due to the onboard supervisor from Waramuri having fishing trips that lasted up to 10 days to travel, whereas the onboard supervisor from La Grange spent 12 hours at sea per fishing trip.

Unlike the data collected from the regional supervisors for the total hauls of landing vessels, onboard supervisors reported the weight of hauls per soaking of the seines, and this further illustrated the elusive nature of large species like snapper. As shown on Figure 4-3, the most productive hauls per soaking were recorded by the onboard supervisor who used bangamary seines in Riverview (Region 4) and Albion (Region 6), and Chinese seines in Lima (Region 2), Windsor Forest (Region 3), and Ogle (Region 4) for fishing. By contrast, the onboard supervisors who targeted snapper and expended greater effort all recorded relatively lower hauls per soaking. For example, as shown on Figure 4-4, at Complex 66, monthly effort was 288 hours with an average weight of hauls per soaking of 559 kilograms (1,232 pounds), whereas at Riverview, average monthly effort was 165 hours, but the average weight of hauls per soaking was significantly higher with a recorded 4,045 kilograms (8,918 pounds). This difference may be due to the larger number of species caught and considered commercial at Riverview compared to Complex 66. Despite the high ratio of effort to hauls, such as at the Complex 66, the effort was considered economically viable because, although smaller quantities of snapper were caught, it is the most expensive fish per kilogram at most of the landing sites in the study and fisherfolk who target snapper may also have additional earnings if the glue is sold separately.

Another interesting trend that emerged at most of the landing sites is that total effort typically peaked during the period with the lowest productivity (the "hard seasons"). Only two onboard supervisors expended greater effort during the most productive period ("good season") at the Albion and Complex 66 landing sites in Region 6. The greater effort resulted in greater total hauls per soaking during the good seasons because the average weight of hauls per soaking was also greater. Moreover, comparable levels of effort in the good and hard seasons did not result in comparable hauls because the productivity of soaking of the seine was lower during the hard seasons. As such, effort was deemed to be a reasonable predictor of haul based on the season in which fishing activities occurred.

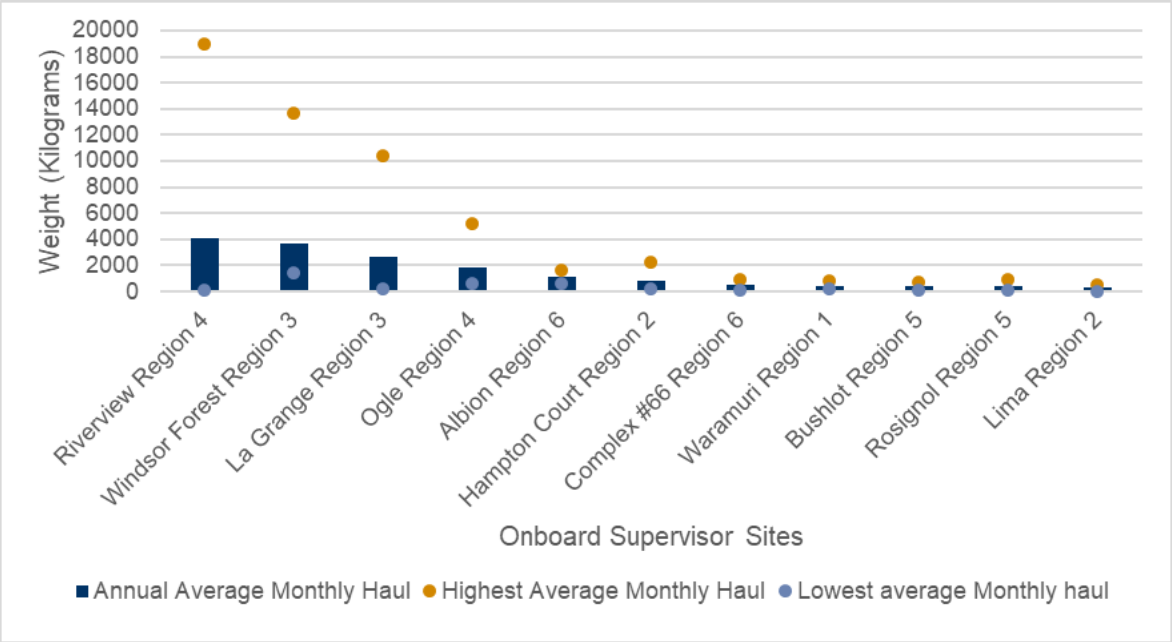

Figure 4-3: Monthly Haul Volumes at the Landing Sites with Onboard Supervisors

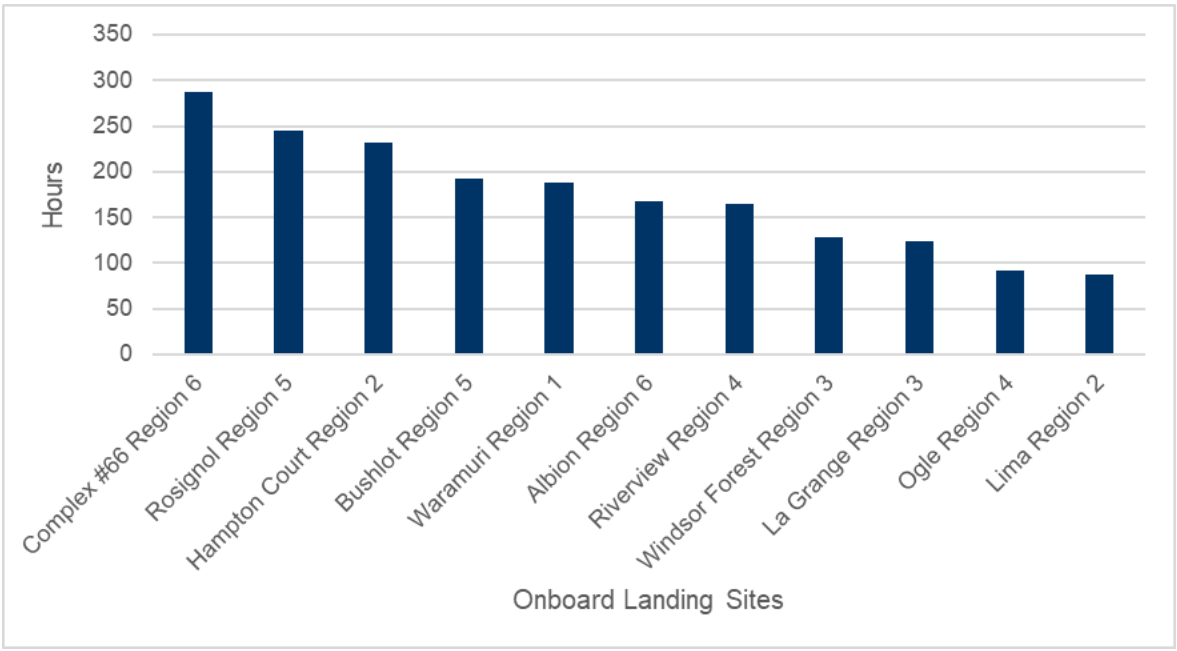

Figure 4-4: Average Monthly Effort Expended by Onboard Supervisors

4.3 Seasonal Productivity

Artisanal fisherfolk in Guyana have a shared belief in the seasonal productivity of fishing activities and this belief also tends to influence their fishing practices and, in particular, effort expended. The peak fishing season, commonly referred to as the “good” season, is believed to occur during periods of the year when waters are warmer (which is believed to lead to an abundance of fishes) and calmer (which is less dangerous and requires less effort to fish). The off-peak season is generally referred to as the “hard” season when waters become colder and rougher. **The good season is generally considered to start in**

May but to peaks from July to September. The hard season is typically considered to be from October to April.

Research suggests that fishes come closer to the shore during the rainy season when river discharges are higher and when the trade winds subside, which means muddy bottoms are not as disturbed (Lowe-McConnell 1962). However, fisherfolk have indicated that fishing productivity does not significantly change among Guyana's wet and dry seasons. The good season is considered to extend from May to September and thus overlaps entirely with the primary wet season (May to July) and partially with the primary dry season (August to October). Similarly, the hard season (October to April) overlaps with the secondary wet season (November to January) and the secondary dry season (February to April).

Fisherfolk have varying beliefs concerning the most productive months for shrimping. Some fisherfolk indicated that shrimp catch generally increases during the closed trawl season, which occurs from August 16 to October 5 annually, and which may allow more shrimp to come closer to shore. Other fisherfolk indicate that the average productivity increases during the dry seasons of February to April and August to September. This intersects with the closed trawl season, and with the spawning season of white belly shrimp that runs from January to April and June to July (Pereira et al. 2017). Spawning seasons may also increase productivity as white belly shrimp may travel closer to shore to spawn in the mangroves.

4.3.1 Regional Supervisor Results

Based on the data collected by the regional supervisors at Charity (Region 2), Zeeburg (Region 3), Riverview (Region 4), and Mahaicony Bridge (Region 5), higher productivity was observed in the good season, as expected (Figure 4-5). However, two landing sites had greater productivity in the hard season than in the good season:

- At Smith's Creek and Morahwanna (Region 1), where no target species are uniformly sought, productivity was higher in the hard season and the highest hauls were in the primary dry season. The most productive month was in October 2019, which is within the hard season and the primary dry season. However, October was also the most productive month at the Mahaicony Bridge landing site (Region 5), where overall productivity was greater in the good season. In addition, fisherfolk from Smith's Creek and Morahwanna share common fishing grounds with fisherfolk from the Charity landing site (Region 2), but the seasonal differences in the haul are starkly different. High fuel prices presented a significant confounding variable that curtailed normal fishing practices in Region 1, particularly in June and July 2019. As a result, the trends that have emerged at Smith's Creek and Morahwanna should be considered with caution and additional data are required to determine whether the trends observed thus far can be representative of practices that generally prevail at Smith's Creek and Morahwanna.
- At the Rose Hall landing site (Region 6), where pin seines are used to target shrimp, hauls were generally consistent over the good and hard seasons and also over the wet and dry seasons. Like Zeeburg, where shrimp is also the target species, the primary and secondary dry seasons were the most productive. However, fishing activities at this landing site were disrupted during the study period as a result of rough tidal conditions which continuously broke down pin seines.

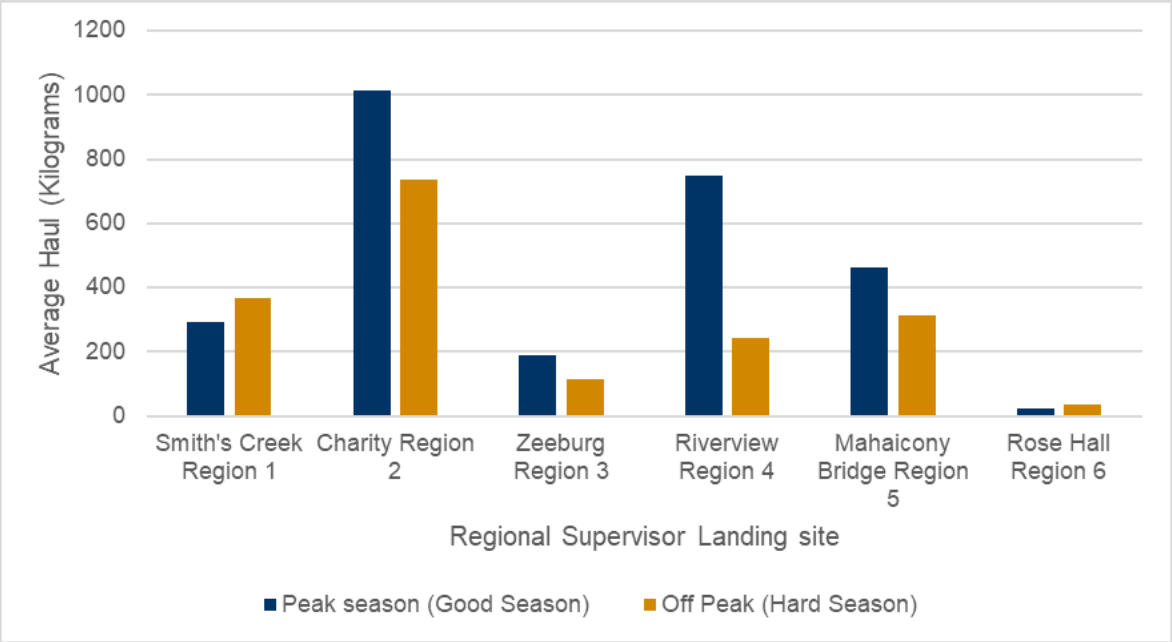

Figure 4-5: Average Productivity of Hauls in the Good and Hard Seasons for Landing Sites with Regional Supervisors

4.3.2 Onboard Supervisor Results

The average productivity of hauls per soaking was higher in the good season for seven of the ten onboard supervisors in Regions 2 to 6 (Figure 4-6). These landing sites were Hampton Court (Region 2), La Grange (Region 3), Windsor Forest (Region 3), Riverview (Region 4), Ogle (Region 4), Rosignol (Region 5), and Complex 66 (Region 6). The difference in productivity was most significant at the La Grange landing site, where productivity was 75 percent greater in the good season. At most of these landing sites, total hauls were also greatest during the primary wet and dry seasons. This is due to the significant periodic overlaps of the good season (May to September), the primary wet season (May to July), and the primary dry season (August to October). However, within the disaggregated timeframes of the good and hard seasons, climatic seasonality was also observed to have influenced haul productivity. Specifically, within the timeframes of the good and hard seasons, greater productivity was recorded during the primary wet season and the secondary wet season for both fishing and shrimping activities. This trend varied at the Zeeburg landing site (Region 3) where data suggest greater productivity for white belly shrimping was associated with the dry seasons.

Within the good season, the productivity of hauls was greatest during the primary wet season for the landing sites in Hampton Court, La Grange, Riverview, and Rosignol. The onboard supervisors at these landing sites all target various species of fishes. Except for Hampton Court, total hauls at these landing sites were also significantly higher during the primary wet season compared to the primary dry season. Moreover, within the hard season (October to April), the productivity of hauls was significantly greater during the secondary wet season than in the secondary dry season at all these landing sites except Hampton Court. The apparent seasonal differences at Hampton Court may be attributed to the numerous challenges that the onboard supervisor encountered and that have hindered data collection (described in detail in Appendix I).

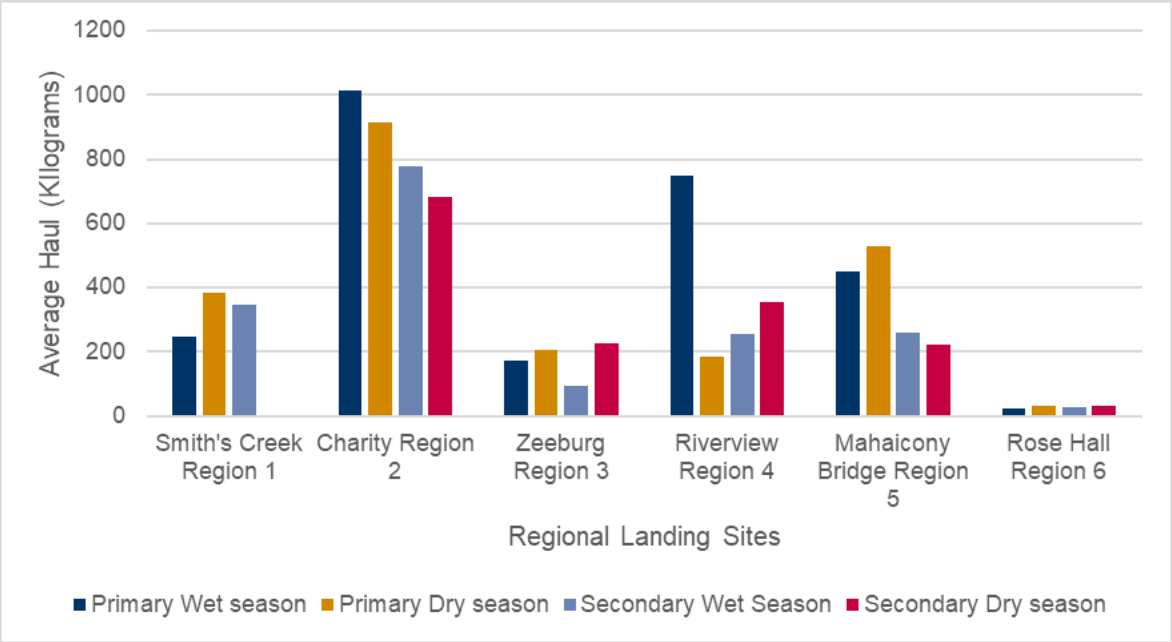

Figure 4-6: Climatic Seasonality of Average Productivity per Haul for Landing Sites with Regional Supervisors

At the Complex 66 landing site, productivity was also higher during the good season as seen on Figure 4-7. However, greater productivity was accompanied by an increase in effort. This is unusual because, at most of the other landing sites, greater effort was expended during the period with lower productivity. In addition, there is a data gap for January 2020 which, if filled, may have narrowed the difference in productivity observed during the good and hard seasons. With the timeframes for the good and hard seasons, the productivity of hauls was greatest during the primary and secondary wet seasons. Based on the supervisor's experience and the total-haul to total-effort ratio, it can be concluded that there is no clearly defined good and hard season for the onboard supervisor's fishing practices.

Within the good season, the productivity of hauls was also greatest during the primary wet season at the landing sites in Windsor Forest and Ogle as seen on Figure 4-8. These onboard supervisors use Chinese seines to target shrimp but, as stated earlier, fishes were the most abundant species caught at the Windsor Forest landing site. At Windsor Forest, total hauls were also significantly higher during the primary wet season. Within the hard season at Windsor Forest, the productivity of hauls was greater during the secondary dry season than the secondary wet season. By contrast, at the Ogle landing site, total hauls were greatest during the secondary wet season because the onboard supervisor expended greater effort at fishing (conducting more fishing trips) than in the primary wet season. Also, the second shrimp spawning season occurs in June to July and therefore intersects both the good season and the primary wet season. The first shrimp spawning season runs from January to April and intersects with the hard season and the secondary dry season. Based on the data available for these two landing sites, it is not clear whether the spawning seasons influenced the productivity of shrimping activities.

Although the data from the onboard supervisors generally corroborated the data from the regional supervisors with respect to the good season being more productive than the hard season (see Figure 4-7), there were outliers in the onboard supervisors' data as well. Three landing sites in Regions 2 to 6 also recorded greater productivity during the hard season:

- At the Lima landing site (Region 2), where the onboard supervisor primarily used Chinese seines to target shrimp, hauls during the good and hard season were relatively uniform, with only a marginal

increase being reported during the hard season. This consistency in haul volumes may be attributed to the supervisor's decision to complement Chinese seine fishing with drift seines and pin seines during the hard season to improve haul. Within the disaggregated timeframes of the good and hard seasons, the greatest productivity of hauls was recorded during the secondary dry season. The greatest total hauls were reported during the primary and secondary wet season. Based on the data available, greater productivity was also associated with the spawning seasons at this landing site. As such, productivity had no clear seasonal trends at this landing site. Additional data are required to draw firm conclusions as to the seasonality of the onboard supervisor's fishing practices.

- At the Bushlot landing site (Region 5), where the onboard supervisor used drift seines with varying mesh sizes to target large fishes like snapper and trout, productivity was significantly greater (65 percent higher) during the hard season. The supervisor indicated that this reversal in seasonality has occurred previously and that this is the second consecutive year in which this was observed; the reasons for this reversal are unknown. In addition, as previously discussed, at this landing site, effort also peaked during the May to September period. Based on the differences observed in the good and hard seasons, productivity based on climatic seasonality also changed. As a result, the average weight of hauls during the primary wet and dry seasons was significantly lower than in the secondary wet and dry seasons. However, within the disaggregated timeframes of the good and hard seasons, productivity was greater during the primary and secondary wet seasons.
- At the Albion landing site (Region 6), where the onboard supervisor targeted bangamary, the productivity of both the average weight of hauls per soaking and total hauls were greater in the hard season as seen on Figure 4-7. However, total effort expended also increased. This is unusual as greater total effort typically occurred and peaked during the season with the lower productivity at other landing sites, including Bushlot. However, increased effort during the more productive period may have been influenced by a deliberate change in fishing practices by the onboard supervisor to access fishing grounds farther offshore. Moreover, total hauls were greater in the hard season than the primary wet and dry seasons. In contrast to other landing sites, the highest total haul was recorded in the primary dry season, and the highest average hauls per soaking were recorded during the primary and secondary dry seasons as shown on Figure 4-8. Based on the ratio of effort to productivity during the good and hard seasons, it may be concluded that there was no clearly defined periodicity of the onboard supervisor's fishing practice. Additional data are required to draw firm conclusions as to the seasonality of the onboard supervisor's fishing practices.

Seasonality of fishing practices of the onboard supervisors from Waramuri and Smith's Creek (Region 1) was not considered in this summary because data are only available from Waramuri for the good season and Smith's Creek for the hard season.

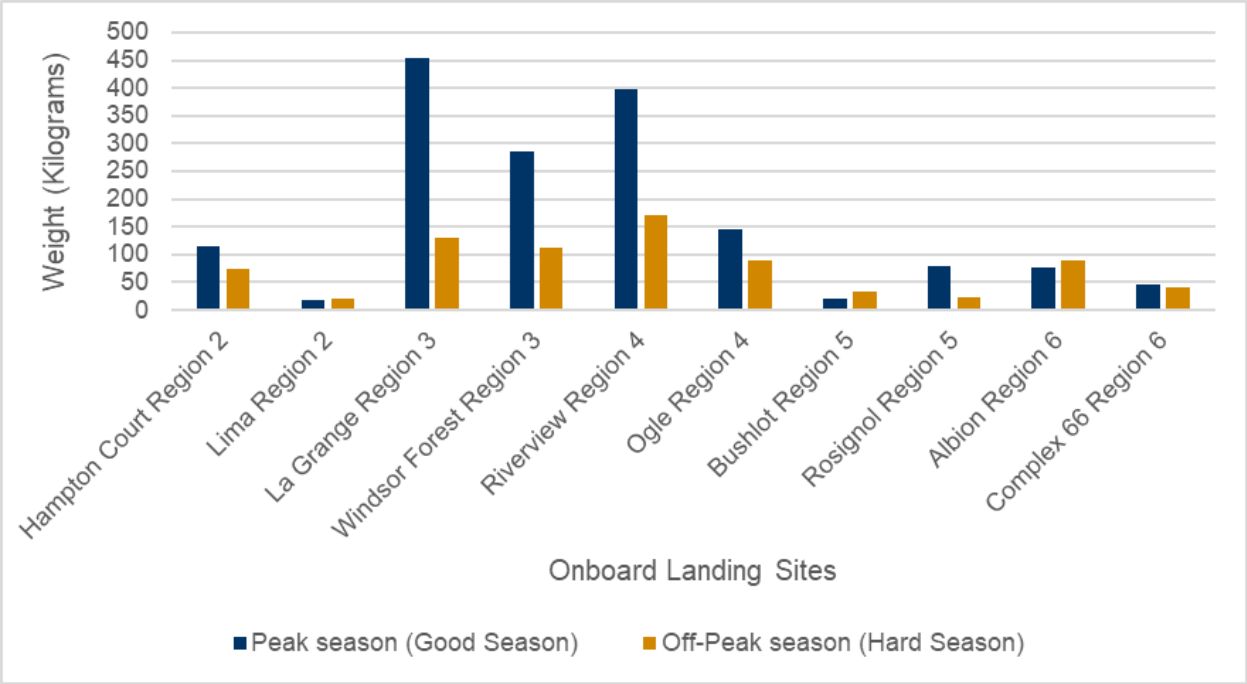

Figure 4-7: Average Productivity of Hauls in the Good and Hard Seasons for Landing Sites with Onboard Supervisors

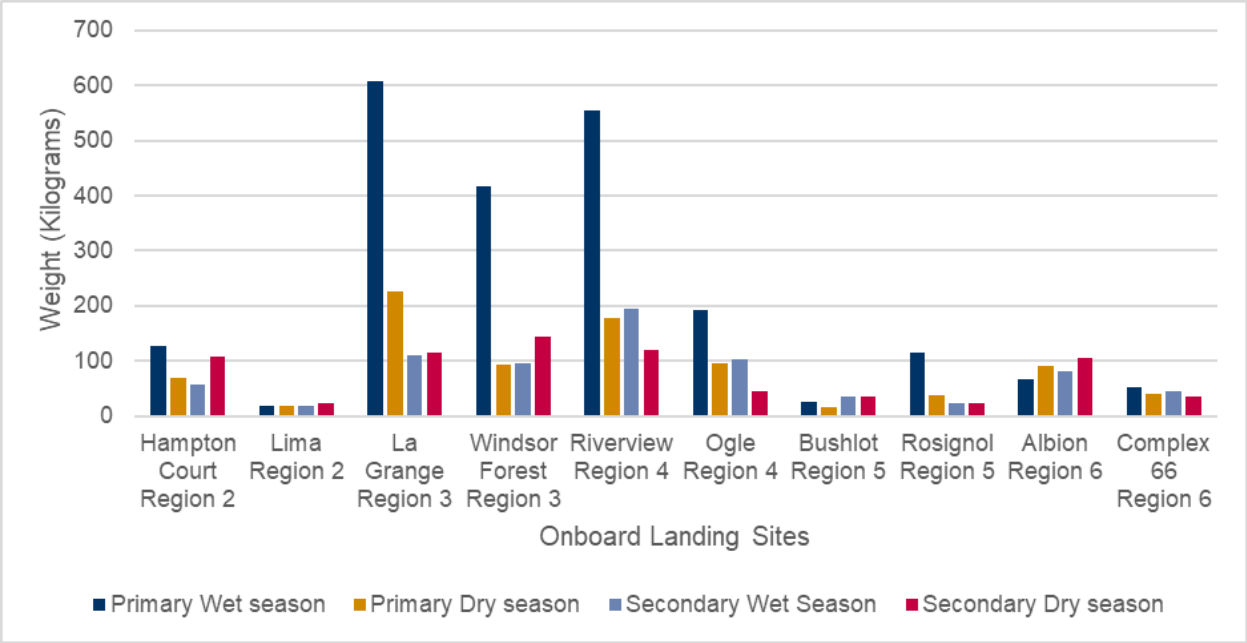

Figure 4-8: Climatic Seasonality of Average Productivity per Haul for Landing Sites with Onboard Supervisors

Figure 4-9 demonstrates the monthly variations in the productivity of hauls for the landing sites. As discussed above, productivity was highest during the primary wet season and this was due to the similar peaks in productivity in May and July 2019. Lowe-McConnell (1962) posited that fishes will be more likely to come closer to shore in the rainy seasons when nutrients are more abundant at the river mouths.

Increased hauls during the good season may also be attributed to the spawning seasons that run from July to September for most of the species caught by the supervisors.

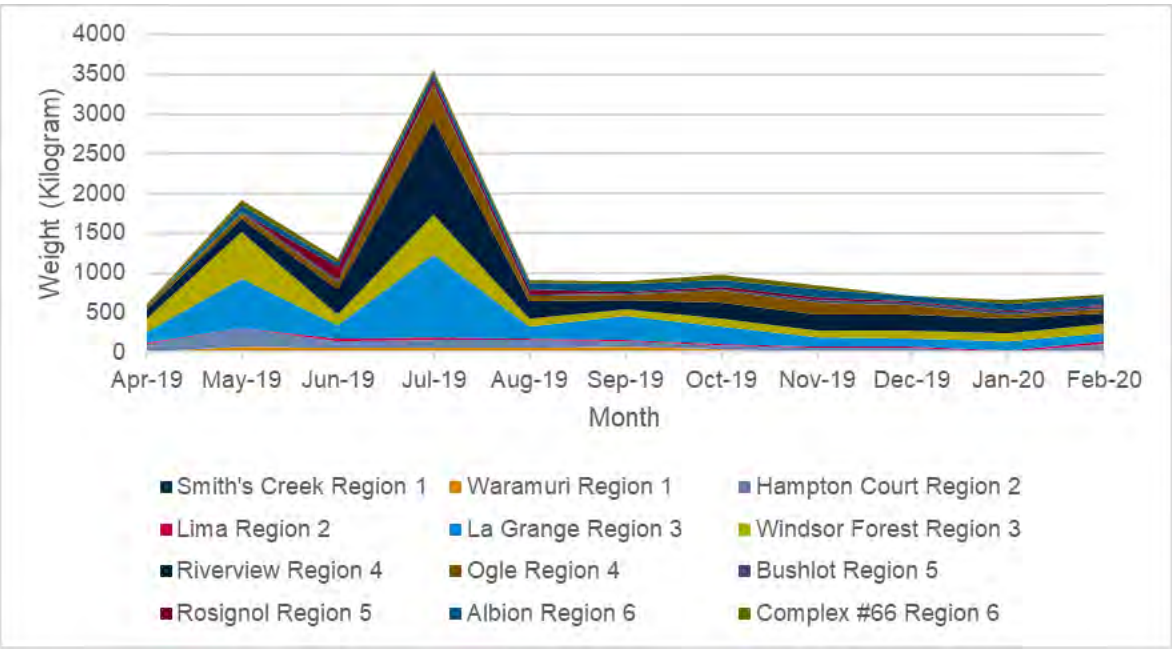

Figure 4-9: Monthly Productivity at Landing Sites with Onboard Supervisors

4.4 Species Diversity

The species diversity of hauls is determined principally by two factors. **The first determinant of species diversity of the haul is the mesh size of the seines used.** In particular, seines with larger mesh sizes typically capture only larger species and larger fishes. Based on data collected by the regional supervisors, the largest mesh sizes were used at the Charity landing site, where a relatively low species diversity of 14 was recorded (see Figure 4-10). Fisherfolk from Charity generally share fishing grounds with fisherfolk from Smith's Creek and Morahwanna, where species diversity was 36. This difference may be partially attributed to differences in gear types because a wide range of seine mesh sizes are used by fisherfolk from Smith's Creek and Morahwanna, while fisherfolk from Charity use snapper seines almost exclusively. Although species diversity of the hauls from seines with smaller mesh sizes are typically higher than from seines with larger mesh, these fishes are typically juveniles and are not considered commercially viable. This is underscored by local consumers' preference for larger species, which results in smaller species of fishes being considered less commercially viable.

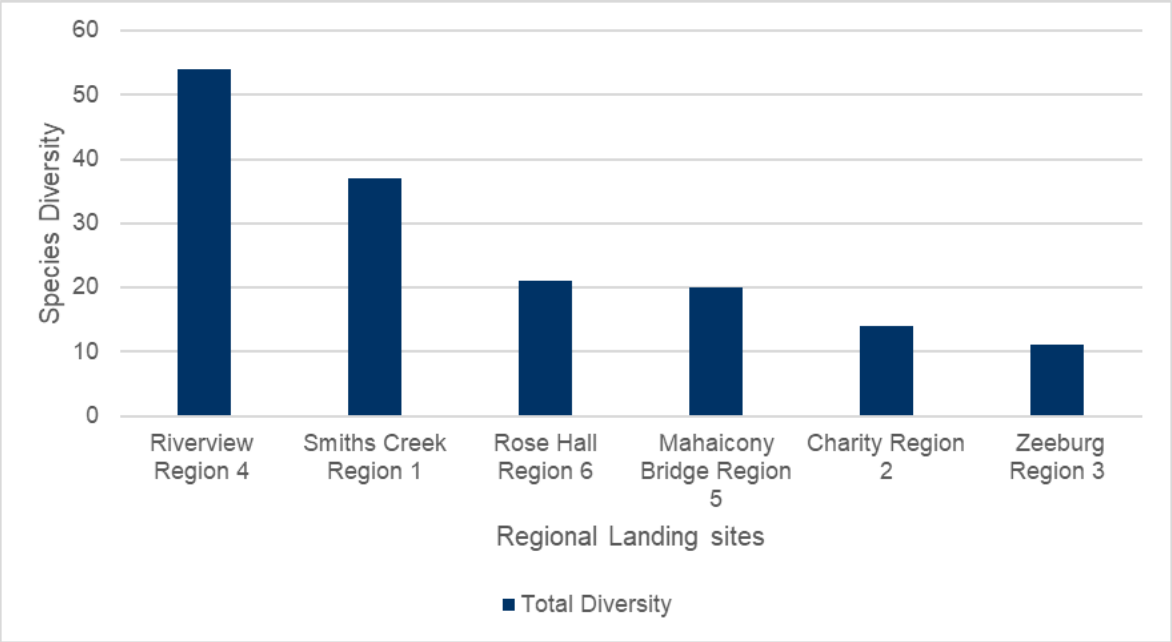

Figure 4-10: Species Diversity at Landing Sites with Regional Supervisors

The second factor that determines the species diversity of the landed hauls is fisherfolk perception concerning what species are likely to be considered commercially viable at their landing sites. In particular, the highest species diversities of 54 and 36 were observed at the landing sites in Riverview (Region 4) and Smith's Creek/Morahwanna (Region 1), respectively. These landing sites were unique because fishes were valued differently compared to other landing sites. For example, bangamary was more highly valued at Smith's Creek/Morahwanna than the other fishing landing sites, while shark species were more highly valued at Riverview than at the other landing sites. However, a wider range of fish and non-fish species were deemed commercially viable by fisherfolk at these landing sites. For example, well developed local and export markets for sea bats and string rays were observed at Smith's Creek, but markets for these species typically do not exist elsewhere in the country. Of the 54 species deemed commercially viable at the Riverview landing site, there were only markets for 50. In particular, although sea bats were sold at Riverview, there were no markets for stingrays. In addition, at the Riverview landing site, species were reported in a disaggregated fashion, and this was not observed at any of the other landing sites. For example, four species each of shark and snapper were reported at Riverview, whereas at most other landing sites these would have been reported as one species each.

The two principal factors influencing species diversity of hauls described above were also observed in the data collected by the onboard supervisors. The lowest species diversity was reported by the onboard supervisors who used drift seines with relatively large mesh sizes to target large species such as snapper, trout, and gillbacker. The onboard supervisors from the Rosignol (Region 5) and Complex 66 (Region 6) landing sites used snapper seines with mesh sizes of 19 centimeters (7.5 inches) and 18 centimeters (7 inches) for fishing and caught 13 and 15 species of fishes, respectively. The onboard supervisor from the Hampton Court landing site (Region 2) used drift seines with mesh sizes of 20 centimeters (8 inches), the largest mesh size used by an onboard supervisor, and recorded a species diversity of only six. In addition, fishing with Cadell lines also produced comparative species diversity. The onboard supervisor from Waramuri who used Cadell lines recorded the lowest species diversity of any survey participant (five species) over a 6-month study period.

Overall, the highest species diversity was reported from fisherfolk using the bangamary seines and Chinese seines. The highest species diversity haul was recorded by the onboard supervisor from the Riverview landing site, where 56 species were caught over the study period. This is consistent with the 54 species reported by the regional supervisor at the Riverview landing site (see Figure 4-11). This was the greatest species diversity recorded by any of the onboard supervisors and was attributed to a larger number of species being considered commercially viable by the onboard supervisor and greater disaggregation of species. The onboard supervisor from the Albion landing site (Region 6) also used bangamary seines and had a high species diversity of 31.

Although the onboard supervisor at the landing site at Windsor Forest (Region 3) also used Chinese seines for fishing, a relatively low species diversity of 12 was recorded. By contrast, onboard supervisors from the Lima (Region 2) and Ogle (Region 4) landing sites had highly diverse hauls, with 28 and 31 species reported. Indeed, species diversity from Windsor Forest is reminiscent of the species diversity reported by the regional supervisor from the Zeeburg landing site (Region 3) where fisherfolk also used Chinese seines and only 11 species were reported. Low species diversity is not typical of Chinese seine fishing and as observed by the study team, more fish species are caught as juveniles and are discarded as bycatch with small mesh nets like the Chinese seine than with other gear types.

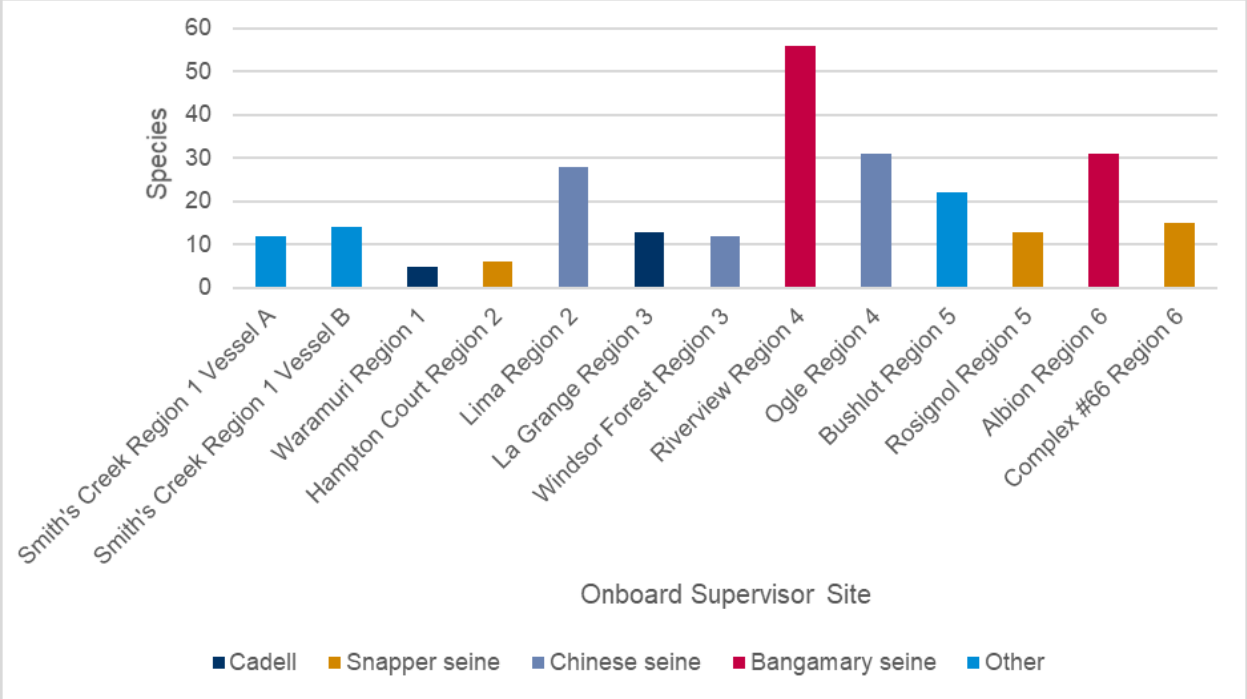

Figure 4-11: Species Diversity at Landing Sites with Onboard Supervisors

4.5 Biometrics

The annual average lengths of the target and most abundant species caught were consistent when fishing gear were similar, even though fishing activities occurred in ecologically different sites. Generally, as seen on Figures 4-12 and 4-13, the annual average lengths of the fishes caught were directly related to the size of the seines used at the landing sites.

Fisherfolk at the Charity landing site (Region 2) and the onboard supervisors from Hampton Court (Region 2), Rosignol (Region 5), and Complex 66 (Region 6) all used large mesh sizes to target larger species like snapper and gillbacker. As a result, the annual average lengths of fish caught at these sites

indicated that most fish had reached maturity. The largest fishes, including snapper, were caught by the onboard supervisor from Hampton Court who also used drift seines with the largest mesh sizes. At the Riverview and Mahaicony Bridge landing sites, the target species was bangamary and at both sites, the annual average lengths of the fishes based on data collected by the regional supervisors were 30 centimeters, which is the length at which this fish is considered sexually mature. Similarly, the annual average length of bangamary caught by the onboard supervisor from the Albion landing site had an annual average length of 31 centimeters, and therefore may also be considered sexually mature. However, the bangamary caught by the onboard supervisors at the Riverview (Region 4) and Albion (Region 6) landing sites had an annual average length of 29 centimeters and did not reach the maturity threshold.

According to data collected by the regional supervisor at Smith's Creek/Morahwanna (Region 1) and the onboard supervisor at Bushlot (Region 5), cuirass was the most abundant species caught and had annual average lengths of 53 centimeters and 58 centimeters, respectively. At both landing sites, the cuirass was sexually mature and most of the other species caught had also reached sexual maturity.

The similarity in sizes was observed for the shrimp caught by fisherfolk at landing sites at Lima (Region 2), Zeeburg (Region 3), Windsor Forest (Region 3), Ogle (Region 4), and Rose Hall (Region 6).

However, a few trends were observed at all the landing sites, as follows:

- All shark species caught are considered juveniles. Although the mesh sizes of most of the seines may be too small to capture mature shark, demand in local markets is for younger sharks. This is because the meat of juvenile sharks is considered more palatable due to its lower ammonia content compared to adult sharks.
- The majority of the fishes caught by the Chinese seines and pin seines were considered juveniles of their species. Some species caught at Lima (Region 2), Windsor Forest (Region 3), Ogle (Region 4), and Rose Hall (Region 6) had reached maturity, but these were only caught in lower quantities. The most frequently caught species of fishes were not sexually mature. At the landing sites in Windsor Forest and Ogle, juveniles of several different species were grouped under the umbrella terms "shine banga" or "flat banga." These fishes were generally discarded as bycatch.

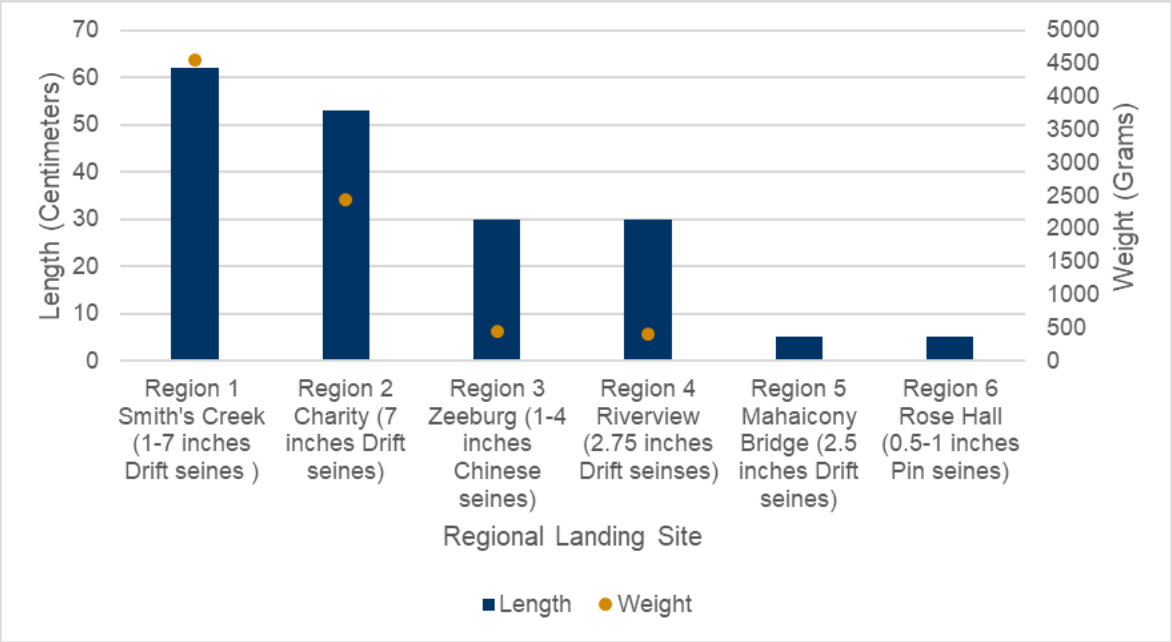

Figure 4-12: Average Lengths for the Most Abundant Species Caught at Landing Sites with Regional Supervisors

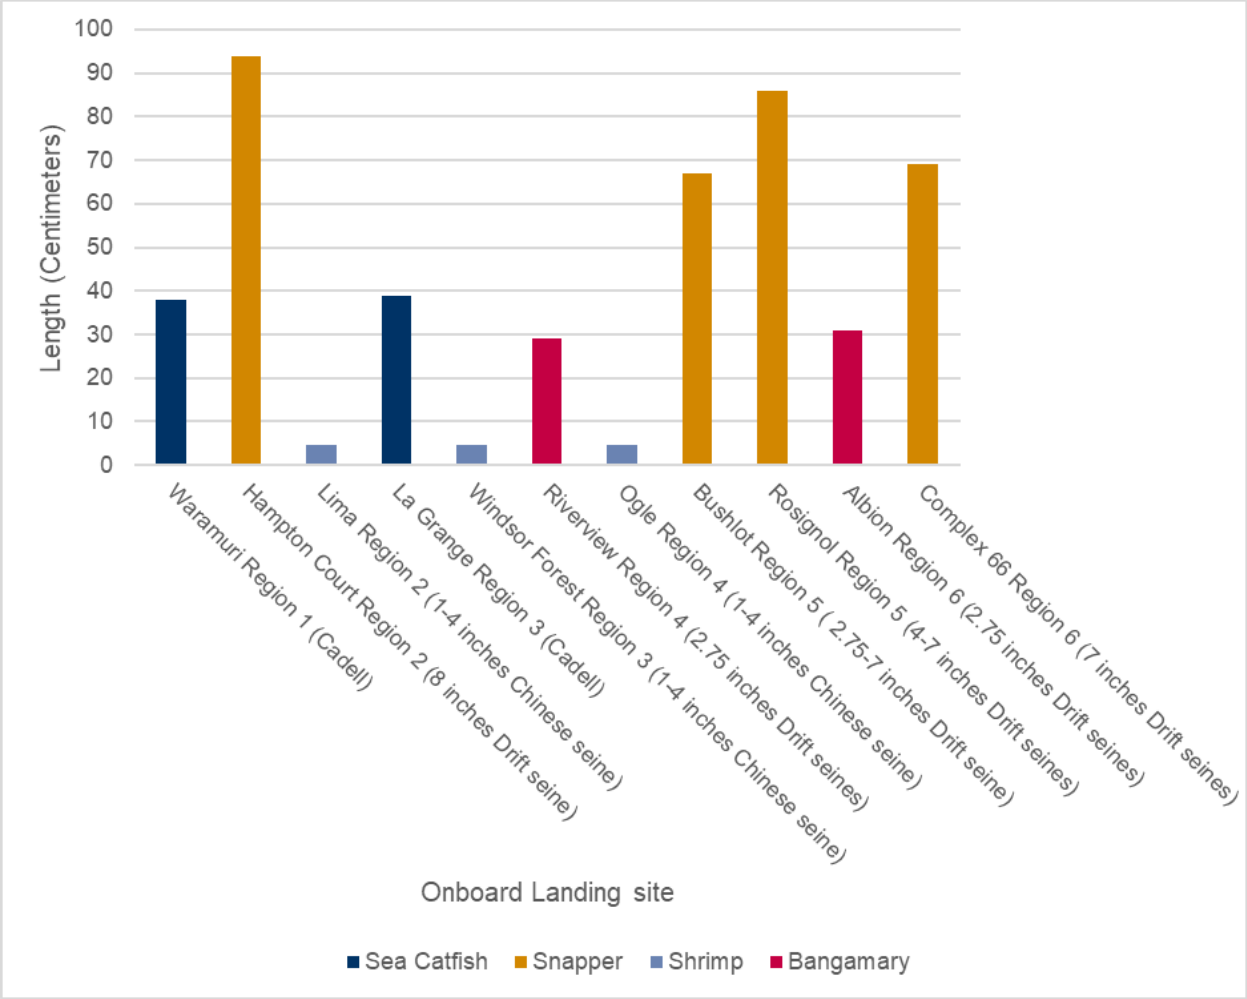

Figure 4-13: Average Lengths of the Most Abundant Species Caught at Landing Sites with Onboard Supervisors

4.6 Prices and Markets

Many factors contribute to the total value of sales per haul, including the species composition of the haul, the total weight of the haul, the size of the fishes that were caught, and bargaining with vendors or other customers. For example, at most of the landing sites where regional supervisors collected data, snapper was the most highly valued species when it was included in the haul and therefore, large hauls in which snapper is the most abundant species caught are likely to be more highly valued. As a consequence, the most valuable hauls were at the Charity (Region 2) landing site, where the target species was snapper and where the largest average weight of hauls was reported. The total value of sales at the Charity landing site was significantly higher than sales at any of the other landing sites (see Figure 4-14). However, the value was likely even higher because the price per kilogram of snapper and trout glue (swim bladders) is equivalent to or higher than the price per kilogram of the flesh of the fishes. However, the price valuation of glue was not part of the data collection effort of this study.

At Riverview (Region 4) and Mahaicony Bridge (Region 5), bangamary was the primary target species. However, unlike the pricing trends at Charity, the target species was not the most highly valued. Instead, bangamary was a medium-value species at these landing sites. This was also observed at Zeeburg (Region 3), where the target species, white belly shrimp, was also a medium-value species. Although not

the target species at Smith's Creek/Morahwanna (Region 1), cuirass was the most abundant species caught and was also a medium-value species at the landing site. In these instances, the value of an average haul is strongly associated with its volume/weight. In particular, when more fishes (hauls are heavier) are caught, earnings are likely to be higher, and when fewer fishes are caught, earnings are likely to be lower.

Fisherfolk also reported that prices are also determined based on the outcomes of bargaining with vendors and other customers. In addition, fisherfolk have reported that there is typically size bias in pricing fishes. For example, bangamary at the Zeeburg landing site was significantly smaller (juveniles) and consequently, significantly cheaper than at other landing sites. At the Rose Hall (Region 6) landing site, where fisherfolk sell hauls directly to consumers in local markets rather than to third party vendors, the prices for most species were significantly higher than those reported by other regional supervisors. The prices per kilogram of target species at other landing sites (snapper, bangamary, and white belly shrimp) were higher at Rose Hall.

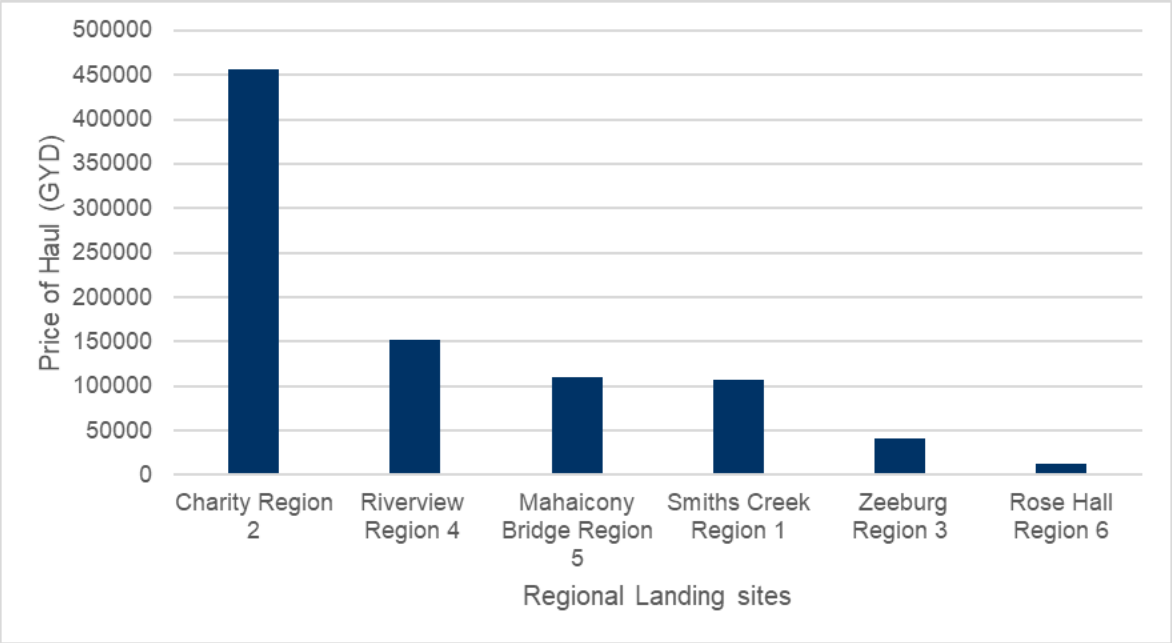

Figure 4-14: Prices of an Average Haul at Landing Sites

4.7 Fishing Grounds

During the study period, the onboard supervisors took GPS waypoints of their fishing points and routes traveling to these fishing points. Generally, **the total distance traveled and the distance offshore at which activities occurred were linked to the supervisor's fishing practices, including the target species and vessel type used.**

The onboard supervisors from Lima (Region 2) and Windsor Forest (Region 3) who used Chinese seines had the smallest traveling range of 20 and 25 square kilometers, respectively. This is due to the static nature of their fishing practices where the pens used to set the Chinese seines are located in a single cluster. However, the pens used by the Windsor Forest onboard supervisor are significantly farther offshore than those used by the onboard supervisor from Lima. Although the onboard supervisor from the Ogle (Region 4) landing site also used Chinese seines for fishing, multiple pens were used in various locations. This resulted in a significantly larger traveling range, and in fishing points also located even farther offshore.

The traveling range of the onboard supervisor from Riverview (Region 4) was significantly different than those of the onboard supervisor from Albion (Region 6). The onboard supervisor from Riverview had a traveling area encompassing 1,041 square kilometers. This was seven times larger than the area covered by the Albion onboard supervisor, who had a 141-square-kilometer traveling area. However, the maximum distance offshore at which fishing occurred was consistent between these landing sites, with both supervisors traveling 32 to 33 kilometers offshore to fish. In addition, the onboard supervisor from Riverview also fished significantly closer to shore (0.4 kilometer) than the onboard supervisor from Albion, whose minimum distance from shore was 2 kilometers. The difference in traveling range and minimum fishing distance may have been related to greater foraging for fishing grounds by the onboard supervisor from Riverview due to the increased competition for fishing grounds. For fisherfolk targeting bangamary, three large landing sites at Hope Canal, Bee Hive, and Enmore are within 10 kilometers of the Riverview landing site.

The onboard supervisor from the La Grange landing site (Region 3) traveled farther offshore (46.5 kilometers) for fishing than any of the other onboard supervisors, almost three times the maximum distance offshore at which the onboard supervisor from Waramuri/Haimokabra (Region 1) fished. Several factors may influence such a large distance to fishing grounds. In particular, the fishing grounds were located at the mouth of the Demerara River, which is a highly traversed area. Traveling farther offshore to fish may have been an attempt to find relatively low-traffic fishing grounds to minimize conflicts and to prevent fishing activity disturbance.

The largest traveling area covered was by the onboard supervisors targeting snapper at Complex 66 (Region 6), with 7,003 square kilometers, and at Rosignol (Region 5), with 6,076 square kilometers (see Table 4-2). These vessels are both licensed to fish in Surinamese waters and fished frequently there during the study period. The snapper vessels generally have larger foraging areas as snapper is a large predator and therefore, more difficult to catch. However, although they have significant traveling ranges, fishing occurs relatively close to shore. Maximum distance traveled offshore by the onboard supervisor from Rosignol (Region 5) is comparable to the farther offshore fishing points recorded by the supervisors from Riverview (Region 4) and Albion (Region 6) who target bangamary. Indeed, the maximum distance traveled by the onboard supervisor from Complex 66 was significantly lower than those of the onboard supervisors from Riverview and Albion. By contrast, the traveling range used by the onboard supervisor from Hampton Court (Region 2) was relatively small and maximum distances fished offshore were even lower than for Rosignol and Complex 66. However, the onboard supervisor indicated that these fishing grounds have been sufficiently productive for years and are not likely to change.

The onboard supervisor from Bushlot (Region 5) uses drift seines with relatively large mesh sizes to target large fishes like snapper and trout. However, the onboard supervisor uses a sailboat and fished closer to shore than any of the snapper vessels from Hampton Court, Rosignol, or Complex 66. Moreover, the haul capacity of the sailboat is lower and this requires the onboard supervisor to take relatively short fishing trips. For example, fishing trips by the onboard supervisor from Hampton Court last for 2 to 8 days, but the onboard supervisor's fishing trips lasted only 12 hours on average. In addition, the onboard supervisor also alternated the seines with different mesh sizes throughout the study period based on success experienced during previous fishing trips in specific fishing grounds. By contrast, the other onboard supervisors targeting snapper consistently used drift seines with mesh size of 17 to 20 centimeters (7 to 8 inches). As a result of these factors, the most abundant species caught was cuirass.

Table 4-2: Distances Covered by Onboard Supervisors

Onboard Landing Site	Traveling Range (square kilometers)	Minimum Distance Offshore (kilometers)	Maximum Distance Offshore (kilometers)	Maximum Distance from Landing Site (kilometers)
Smith's Creek Region 1	1,741	0.22	11	138.41
Waramuri, Region 1	458	0.53	12.5	60.61
Hampton Court, Region 2	272	4	15	21.68
Lima, Region 2	20	0.23	1.37	1.38
La Grange, Region 3	2,226	9.3	46.5	52.69
Windsor Forest, Region 3	25	10.3	10.3	10.3
Riverview, Region 4	1,041	0.4	33	34.3
Ogle, Region 4	151	0.8	14.68	14.68
Bushlot, Region 5	255	0.25	8.5	8.5
Rosignol, Region 5	6,076	1.46	33.06	205
Albion, Region 6	142	2	32.6	36
Complex 66, Region 6	7,003	1.96	23.12	259

Figure 4-15 shows the extent of the fishing grounds used by the onboard supervisors. Although there were only 13 onboard supervisors, significant overlaps were observed in their fishing grounds. For example, fishing grounds were shared by onboard supervisors as follows:

- Smith's Creek and Waramuri overlapped in Region 1
- La Grange overlapped with Windsor Forest in Region 3, along with Ogle and Riverview in Region 4
- Rosignol (Region 5) overlapped with fishing grounds of all onboard supervisors from Regions 5 and 6, La Grange (Region 3), and Ogle and Riverview (Region 4)
- Complex 66 overlapped with Rosignol (Region 5) and Albion (Region 6)

Individual fishing grounds and routes by landing site are shown on Figures 4-16 through 4-27 and discussed in Sections 4.8 and 4.9.

4.8 Summary of Landing Sites with Regional Supervisors

At the Smith's Creek/Morahwanna landing site (Region 1), the main fishing method was drift seines with mesh sizes ranging from 2.5 to 18 centimeters (1 to 7 inches). As a result of these varied methods, no target species was identified, and the most abundant species caught was cuirass, which can be caught using any of the seine mesh sizes used at this landing site. Hauls also included jewfish and stingrays (endangered, threatened, and protected species), as well as shark species—some of which may be considered endangered, threatened, and protected, or vulnerable species. In total, 36 different commercial species of fishes were caught, with a total weight of 80,830 kilograms (178,200 pounds). During the study period, a fuel shortage, which in turn led to high fuel prices, occasionally made fishing trips economically unfeasible. As a result, fuel prices significantly affected the effort expended by fisherfolk; the increased effort during peak season may have resulted in a greater total haul. In total, sales at this landing site during the study period were $26,721,374 GYD ($127,853 USD) based on data collected. Fishes are valued differently at this landing site and a wide range of species are considered commercially viable. In addition, high fuel prices also affected the prices since the increased expenses borne by fisherfolk were ultimately passed on to the consumers in the form of higher prices. The majority of the fishes measured at this landing site had achieved sexual maturity.

The Charity landing site (Region 2) is one of the largest landing sites for inboard cruisers, the largest artisanal fishing vessels. The landing site has an artisanal vessel fleet of 70. Vessels use drift seines with mesh sizes of 10 to 20 centimeters (4 to 8 inches) to target snapper. These vessels have extended fishing trips averaging 15 days at sea. Hauls also included jewfish (endangered, rare, and protected species) and shark species—some of which may be considered endangered, rare, and protected, or vulnerable species. In total, 14 commercial species of fishes were caught, with a total recorded weight of 105,370 kilograms (232,301 pounds). Snapper was the most abundant species caught and accounted for 60 percent of the total recorded weight at the landing site. The May to September 2019 period was the most productive fishing period at this landing site. In total, sales of fishes at this landing site were valued at $54,725,111 GYD ($263,101 USD) based on the data collected. These were the highest earnings at any landing site at which regional supervisors collected data. In addition, fisherfolk at this landing site sell the glue (swim bladders) of snapper and trout separately and have reported that the price per kilogram of glue is frequently higher than the price per kilogram of the flesh of these fishes. If earnings from the sale of glue were not included, it is likely that the total sale value of fishes would be significantly lower. The majority of the fishes measured at this landing site had achieved sexual maturity.

The Zeeburg landing site (Region 3) is one of the largest landing sites in Guyana for vessels that use Chinese seines to target white belly shrimp. The landing site has an artisanal vessel fleet of 30. The landing site is also used for drying white belly shrimp. Fishing activities were significantly affected by infrastructural works at the landing site and by damage to the landing due to spring tides at the end of September 2019, which caused all activities to temporarily cease in October. In total, 11 commercial species were caught with a total recorded weight of 111,535 kilograms (245,892 pounds). White belly shrimp was the most abundant species caught, accounting for 85 percent of the total haul. The species diversity of the hauls is expected to be greater, but most other species caught would have been considered juveniles. In total, sales at this landing site were valued at $31,295,960 GYD ($150,461 USD) based on the data collected. None of the fishes caught at this landing site were measured as being sexually mature.

The Riverview landing site (Region 4) had an artisanal vessel fleet of 30. Most vessels use drift seines with mesh sizes of 7 centimeters (2.75 inches), known as bangamary seines, to target bangamary. A few vessels use drift seines with mesh sizes of 10 centimeters (4 inches) to target snapper. In total, 54 species were caught at this landing site, with a total haul weight of 133,977.5 kilograms (295,369 pounds). Bangamary, butterfish, and trout were the most abundant species caught, accounting

for 36, 23, and 21 percent of the total haul, respectively. Hauls at this landing site included several species of shark including the blacktip shark (endangered, threatened, and protected species) and hammerhead shark, species that are considered vulnerable. Data are not available for the July to September 2019 period (accurate and reliable data were not collected by the regional supervisor; see Appendix N), and it is likely that the total haul would have been higher had these data been included in the data set. Nonetheless, total recorded haul at this landing site was the highest total haul of any of the landing sites at which regional supervisors collected data. In addition, there was a greater species diversity, which was likely due to more species being considered commercially viable, as well as the disaggregation of species caught. For example, four species of shark and four species of snapper were recorded. In total, sales at this landing site were valued at $45,323,998 GYD ($217,904 USD). Shark species were more highly valued at this landing site than at any other landing site. The majority of the fishes measured at this landing site had achieved sexual maturity.

The Mahaicony Bridge landing site (Region 5) had an artisanal vessel fleet of 15. Most of the vessels use drift seines with mesh sizes of 6.5 centimeters (2.5 inches) to target bangamary. In total, 20 species were caught at this landing site with a total haul weight of 118,702 kilograms (261,693 pounds). Bangamary was the most abundant species caught, accounting for 76 percent of the total haul. The second and third most abundant species caught were butterfish and trout, which accounted for 12 and 5 percent of the total haul, respectively. During the study period, the most abundant hauls were recorded over the July to October 2019 period. In total, sales of fishes at this landing site were valued at $29,997,072 GYD ($144,216 USD). The majority of the fishes measured at this landing site had achieved sexual maturity.

The Rose Hall landing site (Region 6) was the smallest landing site in the study. During the baseline data collection in February 2019, four fisherfolk were actively using the landing site. However, the number of fisherfolk operating at the landing site declined due to migration and by February 2020, only two fisherfolk continued to use the landing site. Both of these fisherfolk use pin seines with mesh sizes of 2.5 to 3.8 centimeters (1 to 1.5 inches), targeting shrimp. High tides and rough waters significantly affected fishing activities at this landing site in September 2019 and in January to February 2020. In total, 21 species were caught at this landing site, with a total haul weight of 5,325 kilograms (11,805 pounds). The most abundant species caught was shrimp, accounting for 78 percent of the total haul. Sales at this landing site were valued at $2,509,451 GYD ($12,065 USD) based on the data collected. In general, prices for most species were significantly higher than those reported by other regional supervisors. Some of the fishes caught were measured as being sexually mature, but the majority was juveniles.

4.9 Summary of Landing Sites with Onboard Supervisors

At Smith's Creek, two onboard supervisors collected data. Both vessels used the 2.5-, 5-, 7.5-, 10-, and 12.7-centimeter (1-, 2-, 3-, 4-, and 5-inch) mesh size drift seines to conduct their respective fishing activities. Vessel A was the larger of the two vessels and targeted sea bats that were sold to vendors who exported the haul to Venezuela. This vessel had a haul capacity of 3,000 kilograms (6,600 pounds) and used a 40 hp engine. The vessel typically fished along the Atlantic Coast in Region 1 and recorded a total haul of 19,813 kilograms (43,680 pounds) from 576 hours of effort from November 2019 to January 2020. In total, 12 different species were caught. Based on the average sizes of the sea bats, most were juveniles.

Vessel B at Smith's Creek had a total capacity of 1,000 kilograms (2,200 pounds) and was powered by a 15 hp engine. This vessel fished close to the mouths of the Barima and Waini rivers. Vessel B recorded a total haul of 3,511 kilograms (7,740 pounds) from 924 hours of effort in November and December 2019. The species diversity was 14, with snapper being the most abundant species caught. However, it accounted for only 7.6 percent of the total haul, which shows a balanced haul, a lack of bias, and no

specific target species. Most of the fishes caught by this vessel were measured as having reached sexual maturity.

Waramuri is an Amerindian community on the west bank of the Moruca River, where approximately 20 vessels normally operate, all equipped with outboard engines ranging from 5 to 48 hp. Cadell lines and drift seines were the principal fishing gear used by fisherfolk at this landing site. The onboard supervisor from this landing site who participated in the study used the Cadell method of fishing. The vessel used a 15 hp engine and had a haul capacity of 500 kilograms (1,100 pounds). The supervisor caught at total of 2,753 kilograms (6,069 pounds) from 1,128 hours of effort from May to October. Sea catfish comprised 75 percent of the total haul, which was expected based on the fishing method. The supervisor fished along the coast of Region 1 and accessed these grounds via the Moruca River. All species caught by the supervisor were mature.

Hampton Court is one of the largest landing sites on the Essequibo Coast (Region 2) and is used by vessels that target both fishes and shrimp. Approximately 22 total vessels use the Hampton Court landing site, all of which are outboard cruisers with engine sizes ranging from 5 to 60 hp. The onboard supervisor at this landing site who participated in the study uses a drift seine with mesh sizes of 20 centimeters (8 inches) to target larger species of fishes, specifically the high-value species, gillbacker and snapper. The vessel used has a haul capacity of 907 kilograms (2,000 pounds) and is powered by two 48 hp engines. The supervisor recorded a total of 7,048 kilograms (15,538 pounds) with a total effort of 2,328 hours from April 2019 to February 2020. The majority of the haul comprised gillbacker and snapper with the two species accounting for 56 and 40 percent of total catch, respectively. Hauls were highest during the good season. Within the disaggregated timeframes of the good and hard seasons, hauls were higher in the rainy seasons. In total, six species were recorded by the supervisor, all of which were mature. The supervisor has a general traveling area of 272 square kilometers.

Lima is a smaller landing site in Region 2 that is used by 15 vessels that target fish and shrimp. All vessels are fitted with small outboard cruisers that have engine sizes of 10 to 25 hp. The onboard supervisor who participated in the study principally used the Chinese seine method, but drift seines and pin seines were also used during the hard season (October 2019 to February 2020). Hauls totaled 2,935 kilograms (6,470 pounds) from 952 hours of effort. Shrimp comprised 71 percent of the haul, which is a mixture of white belly and coarse shrimp. Hauls were marginally greater in the hard season, but this may be attributed to the onboard supervisor augmenting fishing practices to increase total catch. Moreover, the primary and secondary rainy seasons were the most productive for this supervisor. The supervisor caught a total of 28 species of fishes and the annual average lengths of these fishes indicated that 12 individuals from these species were juveniles. The supervisor used a small traveling area of 20 square kilometers.

The La Grange landing site is one of the only landing sites in Guyana where almost all fisherfolk still use Cadell lines for commercial fishing. The landing site is on the western bank of the Demerara River. Although the landing site is more inland than the other landing sites surveyed, fisherfolk traverse along the Demerara River to access fishing grounds along the Region 3 and 4 coastlines. Using Cadell lines, the onboard supervisor who participated in the study caught a total of 30,656 kilograms (67,585 pounds) from 1,367 hours of effort. Sea catfish accounted for 75 percent of the haul. Hauls were highest during the good season. Within the disaggregated timeframes of the good and hard seasons, hauls were higher in the rainy seasons. The supervisor caught a total of 13 species, all of which were measured as being sexually mature. The supervisor traveled in an area of 2,226 square kilometers outside the mouth of the Demerara River and fished farther offshore than any of the other onboard supervisors.

Windsor Forest is a medium-sized landing site on the west coast of Demerara in Region 3. Approximately 12 vessels use this landing site, all of which use Chinese seines with mesh sizes ranging from 2.5 to 10 centimeters (1 to 4 inches) as the principal method of fishing. The onboard supervisor at this landing

site who participated in the study recorded a total catch of 40,727 kilograms (89,787 pounds) using both the Chinese seine fishing method and Cadell lines. Bangamary was the most abundant species caught, representing 24 percent of the total haul. A total of 1,464 hours was expended on fishing activities during the study period. Hauls were highest during the good season. Within the disaggregated timeframes of the good and hard seasons, hauls were higher in the rainy seasons. The supervisor caught a total of 12 species including several species of juvenile fishes. Significant quantities of bycatch were also recorded by the onboard supervisor. The supervisor traveled in an area of 25 square kilometers.

The onboard supervisor at the Riverview landing site used a mesh size of 2.75 inches (7 centimeters) to target bangamary. The supervisor recorded a total of 44,601 kilograms (98,328 pounds) from 1,815 hours of effort during the study period. The onboard supervisor also had the more productive soakings of the seine compared to other onboard supervisors. Bangamary comprised 53 percent of the total haul. In total, 56 species were recorded by the onboard supervisor and this was the most species-diverse haul of any of the regional or onboard supervisors. Hauls were highest during the good season. Within the disaggregated timeframes of the good and hard seasons, hauls were higher in the rainy seasons. Most of the species caught by the onboard supervisor were measured as having reached sexual maturity, but four species of sharks, including blacktip and hammerhead sharks, were all immature. The supervisor had a traveling range covering 1,041 square kilometers.

The Ogle landing site is one of the largest landing sites in Region 4 for vessels using Chinese seines. Fisherfolk estimate that approximately 30 vessels use this landing site, most of which are outfitted with outboard cruisers of 15 hp. The onboard supervisor who participated in the study used Chinese seines to target coarse shrimp and the vessel was fitted with a 30 hp engine. A total of 20,473 kilograms (45,135 pounds) was caught and coarse shrimp accounted for 71 percent of the haul. The supervisor had a total effort of 1,095 hours during the study period. Hauls were highest during the good season. Within the disaggregated timeframes of the good and hard seasons, hauls were higher in the rainy seasons. The supervisor recorded a total of 31 species, several species of which were juveniles. This supervisor also reported significant quantities of bycatch. The supervisor had a traveling range covering 151 square kilometers.

Bushlot is the only landing site at which most of the vessels are sail vessels. Fisherfolk indicated that 20 sail vessels are operational at this landing site year-round, but approximately 40 vessels use the landing site during peak fishing seasons. Although the vessels primarily use sails, some are also fitted with small outboard cruisers of 5 to 15 hp. The onboard supervisor who participated in the study used drift seines with relatively large mesh sizes to target large high-value species like snapper and trout. A total of 4,485 kilograms (9,888 pounds) of fishes was caught, of which cuirass and snapper accounted for 28 and 27 percent of the catch, respectively. During the study period, 1,922 hours of effort was expended. In total, the onboard supervisor recorded a species diversity of 22. There was a stark reversal in seasonality at this landing site where the period—typically considered the good season—had significantly lower productivity than the period typically considered the hard season. According to the onboard supervisor, this is the second consecutive year in which this occurred; the reasons for this shift are unknown. The supervisor had a traveling range covering 255 square kilometers.

Rosignol is the largest landing site in Region 5 and a cooperative called the Rosignol Fishermen's Cooperative Society (RFCS) manages the site. According to the RFCS, more than 40 vessels use this landing site, use a range of fishing gear, and are outfitted with outboard cruisers with engines of 25 to 60 hp. The onboard supervisor at this landing site who participated in the study targeted snapper during the study period. The total haul was 3,949 kilograms (8,706 pounds) from 2,208 hours of effort during the study period. Snapper comprised 50 percent of the haul. Hauls were highest during the good season. Within the disaggregated timeframes of the good and hard seasons, hauls were higher in the rainy seasons. In total, 13 species were caught, all of which were mature. The onboard supervisor contends that the good season is becoming shorter and believes that this may be attributed to offshore oil and gas

activities. The supervisor had a traveling range of 6,076 square kilometers that extended from the east coast of the Demerara River to the coast of Suriname.

Albion is one of the largest landing sites in Region 6 and fisherfolk have indicated that 60 vessels use this landing site. All vessels are fitted with outboard cruisers with engine sizes ranging from 15 to 50 hp, most of which target bangamary. The onboard supervisor at this landing site who participated in the study targeted bangamary. The supervisor recorded a total of 11,472 kilograms (25,291 pounds) from 1,673 hours of effort over the study period. Similar to the Bushlot landing site, hauls were greater during the hard season and unlike most of the other landing sites, hauls were more productive during the primary dry season. In total, the supervisor caught 31 species; only one (jewfish) was a juvenile of its species. The supervisor had a traveling range covering 142 square kilometers.

Complex 66 is the largest landing site for artisanal fishing vessels in Region 6 and one of the largest landing sites in Guyana. The site is also managed by a cooperative called the Upper Corentyne Fishermen Coop Society. Approximately 140 vessels routinely operate at this landing site and more than 200 vessels during the peak fishing seasons. The onboard supervisor who participated in the study at this landing site targeted snappers. The total haul was 5,588 kilograms (12,319 pounds) using a total effort of 3,168 hours during the study period. Hauls and effort were highest during the good season. Within the disaggregated timeframes of the good and hard seasons, hauls were higher in the rainy seasons. The supervisor caught a total of 15 species, all of which were sexually mature. The supervisor had the largest traveling range covering an area of 7,003 square kilometers extending from the mouth of the Corentyne River to the mouth of the Suriname River.

5. ADDITIONAL FINDINGS AND INFORMATION

5.1 Glue

In recent years, the demand for glue (swim bladders) of several species of fishes has increased significantly in local markets (see Figure 5-1). Local fisherfolk have indicated that this demand originates primarily from Chinese markets where glue is used as an aphrodisiac and also for making some types of beer. In addition, significant quantities of glue were exported and some fisherfolk also preserve the glue for sale by salting and drying. Fisherfolk who harvest glue also sell the meat of the fishes from which the glue is taken.

Glue is sought primarily from snapper and trout, and from cuirass to a lesser extent. Based on feedback from the fisherfolk and supervisors, the glue from grey snapper is sold for the highest price. The increase in the demand and price for glue has led fisherfolk to make certain operational changes to maximize profits through increased efficiency, such as increased targeting of snapper, longer fishing trips to maximize the volume of snapper caught, and increased de-gutting at sea to allow more fishes to be caught per haul.

Due to the high demand, glue is frequently sold separately from other fish products at prices per kilogram that were occasionally even higher than the prices per kilogram of the flesh of the fishes. Fisherfolk who harvest glue for sale separately have indicated that approximately 50 percent of profits from a fishing trip come from the sale of glue. The increased targeting of snapper and trout is similar to the case of the totoaba (*Totoaba macdonaldi*). Like snapper and trout, the totoaba belongs to the Sciaenidae family and as such, has a large swim bladder relative to its overall body size. The totoaba was overfished in Mexico for export of its glue to China and has since been classified as a critically endangered species.

The prices at which glue was sold varied throughout the year, largely in response to external factors. Glue prices reportedly declined in September and October 2019 due to lower demand for exports to China, which was reportedly related to the protests in Hong Kong. As a result, there was a surplus in the local

marketplace. Fisherfolk at the Charity landing site (Region 2) indicated that the price decline challenged the economic viability of their fishing activities and some opted to store the glue harvested from the fishes for sale until market prices once again increased. Before the decline in prices for glue, it was reported by several supervisors that fisherfolk were increasingly targeting snapper because of the high price of its glue. This resulted in an oversupply on the local markets of the fish, which also resulted in prices per kilogram for the flesh of the fish to decline. This relationship between market prices of different fish products underscores the economic vulnerability of fishing-dependent communities and inter-related nature of the markets for fishing-related commodities.

It is expected that the COVID-19 pandemic may have triggered another decline in demand, thus reducing exports of the glue to China and consequently, the price of glue. The glue industry is one that needs to be studied further to better understand its role in influencing artisanal fishing practices.

Figure 5-1**: Fisherfolk Sorting Glue (Swim Bladder) for Sale**

5.2 Bycatch

Since bycatch was not recorded by all of the supervisors, it could only be quantified for hauls from the onboard supervisors who used Chinese seines for fishing from landing sites at Lima (Region 2), Windsor Forest (Region 3), and Ogle (Region 4). Bycatch was also reported by the onboard supervisor from the Bushlot landing site (Region 5). Based on the data collected, bycatch was 38.5 percent of the volume of the total haul at the Windsor Forest landing site and this was the highest quantity of bycatch reported by any of the onboard supervisors (see Figure 5-2). At the Lima and Ogle landing sites, bycatch was 5 percent and 28 percent of the volume of the total hauls of these landing sites, respectively. The main bycatch species from Chinese seine fishing were jellyfishes. Bycatch was also comprised of several other species that are typically considered non-commercial at these landing sites, such as rockhead, Chinese butterfish, flounder, and some species of herring. At the Windsor Forest and Ogle landing sites, the onboard supervisors caught several species that were classified as “flat banga”’ or “small banga” as an umbrella term for the juveniles of several species of fishes that were considered too small to be marketable. At the Bushlot landing site, bycatch represented approximately 15 percent of the volume of the total haul and was comprised mostly of stingrays.

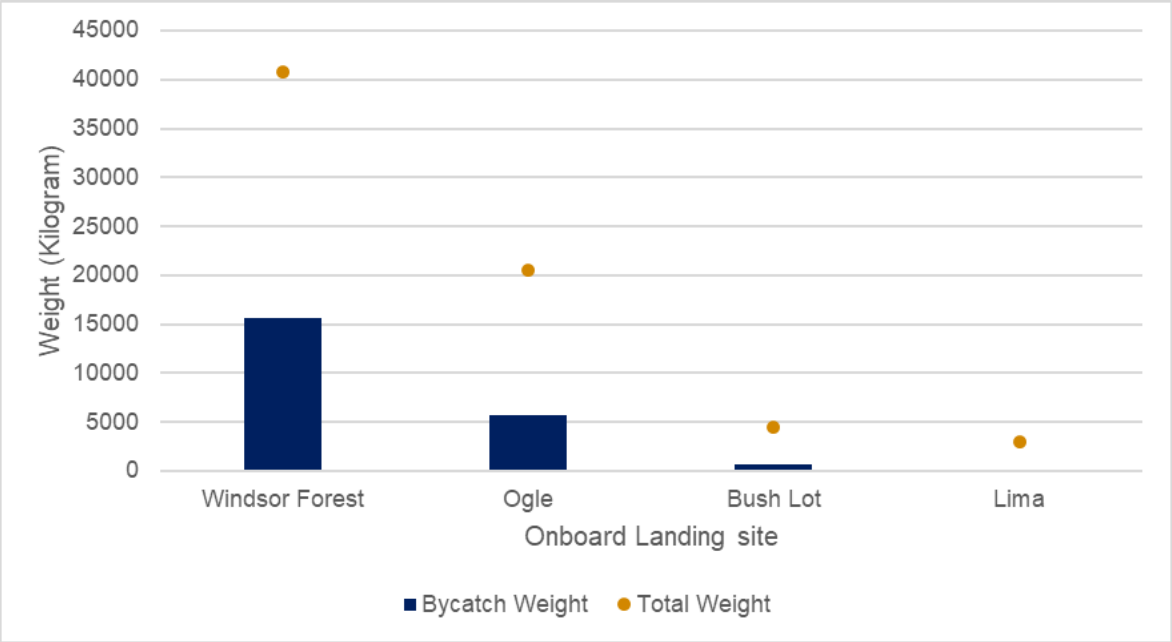

Figure 5-2: Bycatch Weight and Total Haul Weight Recorded by Four Onboard Supervisors

Other onboard supervisors reported bycatch species, but these were not quantifiable, including the following species:

- Marine turtles were caught in seines by the onboard supervisors at Smith's Creek (Region 1), Hampton Court (Region 2), and Complex 66 (Region 6). The main species caught were adult leatherback turtles. All of the supervisors indicated that the turtles were removed from the seines due both to the awareness of the important special status of sea turtles and to superstitions held by the fisherfolk. Some fisherfolk believe that catching turtles leads to lower future hauls while others believe that the turtles are crying (as a result of excretion from the turtle's eyes). In general, the majority of artisanal fisherfolk in Guyana are thought to release any turtles they may catch.
- A nurse shark was captured but released from a Cadell line by the onboard supervisor from the La Grange landing site (Region 3) (see Figure 5-3). Generally, artisanal fisherfolk who catch large sharks release them because it is not deemed commercially viable and would also account for a significant percentage of the haul capacity of the vessel.

No marine mammals were recorded as bycatch by any of the supervisors.

Figure 5-3: Nurse Shark Hooked and Released by the La Grange Onboard Supervisor

5.3 Sargassum

Sargassum is a type of floating seaweed, as shown on Figure 5-4. It is brown in appearance and occupies large areas on the surface of the ocean. During the February to May 2019 period, supervisors reported that significant quantities of sargassum had entered Guyanese waters and created serious impediments to their fishing activities. In the first instance, sargassum became easily entangled in the seines and in so doing, occupied space in the seine that otherwise could be taken up by commercial hauls. Sargassum also blocked the mesh of the seines and thereby prevented fishes from entering and being captured. The onboard supervisor from the Ogle landing site (Region 4) reported that up to 227 kilograms (500 pounds) of sargassum were caught on a single fishing trip. In addition, sargassum was an even greater nuisance when fisherfolk returned to shore; they had to clean the seaweed out of the seine, which meant losing up to a day of fishing activity just to clean the seine according to some supervisors.

The prevalence of sargassum subsided with the onset of the primary rainy season. However, the proliferation of sargassum resumed in early 2020 when the waters began to warm. Fisherfolk will continue to experience challenges and losses when sargassum is prevalent, but this may be mitigated if there is consumer-based demand for this seaweed.

Figure 5-4: Sargassum Pulled Up in an Onboard Supervisor's Seine

5.4 Interactions with Endangered, Threatened, and Protected Species

Fisherfolk reported interactions with several endangered, threatened, and protected species during the study period, including the following interactions:

- Leatherback and green turtles were seen or caught by onboard supervisors in Regions 1, 2, 5, and 6. In addition to the turtles caught in the seines by fisherfolk in Regions 1, 2, and 6, a dead turtle washed up to the Bushlot landing site (Region 5) during the July to September period, as seen on Figure 5-5. The carcass had cuts on its body and fisherfolk believed that the turtle was injured by the propeller of an industrial fishing vessel.
- Manatees, also commonly called sea cows, were observed in the Demerara River outside the koker (sluice) at the La Grange landing site (Region 3) (see Figure 5-6). Fisherfolk from the Riverview (Region 4) landing site also reported sightings of manatees.
- Jewfish was included in the hauls from three landing sites namely Smith's Creek (Region 1), Charity (Region 2), and Albion (Region 6). Catches of jewfish in the hauls were reported across several months during the study period for these landing sites. It was not targeted by any of these fisherfolk, but was considered a commercial species when caught. At the Smith's Creek and Charity landing sites, jewfish was a medium-value species. The jewfish caught at Smith's Creek and Albion were juveniles, but the fish caught at Charity had reached sexual maturity.
- Stingrays were reported in the hauls at landing sites in Smith's Creek (Region 1), Riverview (Region 4), Ogle (Region 4), and Bushlot (Region 5). Commercial markets for string rays were only available at the Smith's Creek landing site where it was a lower-value species. Some fisherfolk at the Riverview landing site also considered string rays as a marketable species, but there were no commercial markets. At Ogle and Bushlot, stingrays were either released or discarded as bycatch. However, similar to the superstitious beliefs about catching turtles, many fisherfolk believe that catching stingrays is taboo because it will reduce total hauls over the long term.

Figure 5-5: Turtle Carcass Washed up at Bushlot.

Figure 5-6: Photo of Manatees taken at the La Grange Landing Site

- For this study, sharks were not disaggregated by species at most of the landing sites. However, based on the prior experience of the study team and observations made, the majority of shark hauls comprised blacktip shark. In particular, blacktip shark was caught in abundance at landing sites in Smith's Creek (Region 1), Charity (Region 2), La Grange (Region 3), Riverview (Region 4), and Albion (Region 6). All of these were juveniles of the species.

- Other species of sharks were caught by fisherfolk from the Riverview landing site. At this landing site, several species of sharks were recorded including the green shark, hammerhead shark, and sand shark.

5.5 Other Marine Species Observed

During the study, several marine birds were observed by the onboard supervisors. These include pelicans, egrets, frigate birds, and ibises. Marine birds have a symbiotic relationship with the fisherfolk where they have become very dependent on mainly Chinese seine fisherfolk to provide food that comes from their bycatch (see Figure 5-7). The birds typically wait until the fisherfolk commenced hauling in their seine, and feed on the bycatch that the fisherfolk would discard into the water. A similar scenario occurs onshore, where egrets clear all scraps of shrimp from the vessels.

Figure 5-7: Birds Feeding on Bycatch from Chinese Seine Haul

6. CONSIDERATIONS FOR FUTURE RESEARCH AND REPORTING

This study has collected critical information on Guyana's artisanal fishing sector in a short period. This was the first study of its kind in Guyana, covering the entire coast of Guyana; the type of information collected is unprecedented. In addition, the methodology and approach of using locals within the fishing community to implement the project has allowed for capacity and relationship building at the selected landing sites. The data collected have been compiled into a comprehensive database comprising copies of the data sheets, images taken by the supervisors, footage of fishing trips from video monitoring of some of the onboard supervisors' fishing trips, and GPS tracks and waypoints marked by the onboard supervisors. The data were also analyzed and presented in reports including quarterly reports and this final report.

Against this backdrop, continuing and expanding the study is strongly recommended in order to:

- Allow for additional data to be collected to fill data gaps for landing sites where external factors significantly disrupted fishing activities or the quality of data collected (for example, a full 12-month data set was not able to be collected for this study due to the challenges associated with COVID-19).

Analysis based on complete data sets will enhance understanding of the seasonal productivity of the artisanal fishing sector including whether anomalous trends observed in this study may be attributed to factors unique to the landing sites at which they occurred, or whether they are part of more regional patterns. Continuation of the study over the short and medium term will also serve to provide current information on how the artisanal fishing sector is evolving and critical issues occurring.

- Contribute to local content by providing capacity building for artisanal fisherfolk. As a result of the study, 19 supervisors have been trained in using digital cameras, measuring basic biometrics of marine species, and recording disaggregated data pertaining to their livelihood. The 12 onboard supervisors were also trained in the use of GPS units that they have integrated into their fishing practices for trip planning and navigation. Cameras, scales, and GPS units, as part of the project's arrangements, were left with the supervisors when the project ended. If the study is expanded to other landing sites, capacity building could also be provided to additional fisherfolk as well as an opportunity to provide additional equipment that could enhance the project's credentials and promote health and safety through assistance with equipment such as first aid kits, life vests, and flares.
- Contribute to local content as many supervisors indicated that the stipend provided for volunteering to collect data contributed to appreciable improvements in their quality of life and consequently their goodwill toward the oil and gas industry. These benefits could continue and expand if the study is extended and/or expanded.
- Maintain an active network of fisherfolk who can aid in the dissemination of information and, if required, could be called upon to assist with responding to unplanned events.
- Enhance the valuation of artisanal fishing activities particularly if additional landing sites are included in the study. This will allow for more robust analysis of fishing activities and could aid in understanding the overall economic value of fishing in Guyana.
- Continue to provide a clearer understanding of the artisanal fishing sector. While fisherfolk, and to a lesser extent national institutions, have a good understanding of the sector in terms of species targeted, pricing, seasonal variations, fishing grounds, etc., the analyses and presentation of the data collected have provided a clearer picture of the sector in a more organized and scientific manner, which can be improved upon with the continuation and expansion of the study.

Continuation and expansion of the study presents the following opportunities:

- Augment data collection for other studies focusing on turtles, marine birds, marine mammals, and any other endangered, threatened, and protected species that fisherfolk have observed.
- Include data collection from industrial fishing activities (trawlers).
- Considering that fisherfolk are perhaps the most direct stakeholders for offshore oil and gas activities, conduct continuous engagement with this stakeholder group, as it allows for immediate and proactive action to be taken related to fisherfolk concerns on the potential impacts on artisanal fishing.
- Communicate the findings of the study to a wider national and international audience using various media such as articles, posters, booklets, and presentations.
- Publish the findings of the study in scientific publications.

In addition, continuation and expansion of the study presents an opportunity to collect data on important topics and gaps in the study's analysis, such as:

- Over the months of April, May, and June 2019, sargassum continued to significantly affect the coast of Guyana. Fisherfolk were in a constant battle with this phenomenon and it caused significant downtime for the fisherfolk since entire days were dedicated to cleaning sargassum from seines.

- The start of the rainy season in May to June led to a change in species diversity in catch at the landing sites. In addition, some fisherfolk became sick with flu-related illnesses that caused them to not go to sea for a number of days.
- The price for “glue” from several species was reduced at many landing sites. Fisherfolk have shared their views on the reasons for the decline. Some fisherfolk believe that supply exceeded demand and drove down the price. Other fisherfolk assert that exports of “glue” to European markets have been banned and this has resulted in the drop in demand. Other fisherfolk believe that the buyer of “glue” on the local market illegally exports it to China via Hong Kong and the unrest in Hong Kong made exports using this route more difficult.

APPENDIX A FISH SPECIES LIST

Species Name	Common Name	Photograph of Fish
Micropogonias furnieri	basher, basha [a]	
Cynoscion acoupa	grey snapper	
Cynoscion virescens	trout	
Cynoscion leiarchus	shine eye	

Species Name	Common Name	Photograph of Fish
Nebris microps	butterfish / butterhead	
Carcharhinus limbatus	blacktip shark [b]	
Carcharhinus porosus	san shark	
Sphyrna lewini	hammerhead shark	

Species Name	Common Name	Photograph of Fish
Rhizoprionodon porosus	green shark	
Chaetodipterus faber	spadefish / donkey fish	
Sciades props	kukawri [c]	
Batrachoides surinamensis	pacu	

Species Name	Common Name	Photograph of Fish
Macrodon ancylodon	bangamary [d]	
Stellifer rastrifer	Rockhead / white / rat mouth	
Ctenosciaena gracilicirrhus	brickhead / rock head	
Scomberomorus cavalla	kingfish	

Species Name	Common Name	Photograph of Fish
Scomberomorus brasiliensis	mackerel	
Xiphopenaeus kroyeri	coarse shrimp / seabob	
Cynoscion sp.	bangamary [d]	
Odontognathus mucronatus	netly	

Species Name	Common Name	Photograph of Fish
Trichiurus lepturus	silverbelt	
Lonchurus elegans	Chinese butterfish	
Nematopalaemon schmitti	white belly shrimp	
Achirus achirus and Symphurus plagusia	flounder	

Species Name	Common Name	Photograph of Fish
Centropomus undecimalis	snook	
Farfantepenaeus sp. and *Litopenaeus* sp.	prawn [e]	
Bagre bagre	sea catfish	
Lobotes surinamensis	paggie / sea congo	

Species Name	Common Name	Photograph of Fish
Cathorops spixii	spring cuirass	
Cathorops sp.	round head	
Cathorops sp. and *Sciades* sp.	cuirass	
Sciades parkeri	gillbacker	

Species Name	Common Name	Photograph of Fish
Megalops atlanticus	cuffum / tarpon	
Genyatremus luteus	annafoke / old wife	
Mugil cephalus	Suriname mullet	
Anchoa spinifer	small herring	

Species Name	Common Name	Photograph of Fish
Elops saurus	long john	
Pomatomus saltatrix	salmon	
Harengula humeralis	shad	
Brachyplatystoma vaillantii	lau lau	

Species Name	Common Name	Photograph of Fish
Sciades couma	cuma cuma / blinka	
Cetengraulis edentulus	big eye herring	Echiophis punctifer	mud eel	
Cynoscion similis	black tail basha	

Species Name	Common Name	Photograph of Fish
Pellona harroweri	mail boy

APPENDIX B LANDING SITE ASSESSMENT QUESTIONNAIRE

Landing site Assessment

Landing Site: _____ **Date:** __/ __/2019

Interviewer: _____

Name of Fisherman: _____ **Telephone Number:** _____

1. What is the best/quickest way to make contact with you again?

   _____

2. How long have you been a fisherman? _____
3. Type of vessel and engine size: _____
4. Where do you live? _____
5. Is fishing the most important livelihood in your village or town? □Yes □ No

   _____

6. How many hours (soak time) a day do you spend fishing? _____
7. Number of fishing trips per day/ per week/ per month: _____
8. Number of days per week spent fishing: _____
9. Location(s) fished/preferred fishing zones:

   _____

10. Do you travel directly to your preferred fishing zone from the landing site?

    _____

11. What type and size of seine do you use to fish? _____,_____
12. How many crew members participate in an average fishing trip? _____
13. During this fishing season how much catch (lb., kg or basket) have you been obtaining per fishing trip?

    _____

    _____

14. What species do you frequently catch in your fishing zones?

    _____

    _____

15. If possible, indicate the point of sale of your catch? _____
16. During this season what are the prices of the main commercial species you catch?

    _____

    _____

17. What would you say are your main expenses per fishing trip?

    _____

18. Have you observed any important variation in fishing landings among seasons? and years?

    _____

    _____

19. Do you think that the average size of main species have changed?

_____

20. Which are the months of the year when the best catches are recorded?

_____

21. What factors do you think contribute to this?

_____

22. What are the main challenges that affect your fishing?

_____

23. Do you participate in any other income providing activities to supplement fishing?

_____

24. Will you be willing to being contacted in the event of an oil spill?

_____

25. Are there any women who fish at this landing site? □Yes □ No
26. What role if any do women play in the fishing industry in your community? Eg. selling, cleaning shrimp, etc

_____

_____

27. Do you belong to a fishing co-op or union? □Yes □ No
    If yes, please indicate the name of co-op or union? Do women belong to the co-op?

_____

Participatory Fish Survey

1. Is there anyone, including former fishermen with knowledge of this landing site's fishing activity who would be willing to help with daily surveys?

_____

2. Are they unemployed currently? _____
3. Are they respected by the fishermen at the landing site?

_____

4. Would the fishermen be willing to give fishing data for research purposes?

_____

5. For sites selected for Component 2, would you allow one of your crew members to facilitate onboard data collection? This will involve recording your location, the types of fish caught and taking pictures.

_____

6. Are you willing to allow a video camera on-board? □Yes □ No

7. How many boats operate at this landing site?

   _____

8. What types of vessels operate at the site?

   _____

   _____

Multi-Year Turtle Research Programme

1. Do you or other fishers ever see marine turtles surfacing during your fishing activities? □Yes □ No

   If so, which species and what approximate size (small, dinner plate size; medium; or large)?

   _____

2. Do you or other fishers ever catch them in your fishing gear? □Yes □ No

   If so, which species and what approximate size (small, dinner plate size; medium, or large)? Are they usually alive or dead?

   _____

   _____

3. Is there a particular season, time of day, tidal cycle or prevailing wind when turtles are seen/caught? □Yes □ No _____
4. Is there a particular type of area (rocks, mangroves, islands, beach, river mouth etc.) and/or water depth where the turtles are usually found?

   _____

   _____

5. Are there any locations in your fishing zones where you frequently encounter turtles?

   _____

6. Would you be willing to help in catching turtles for research activities? □Yes □ No
7. What do you do if you accidentally catch a turtle?

   _____

8. Do the turtles appear injured/harmed after being trapped? □Yes □No
9. Can you recall in the past five years (2013 to present) if the number of turtles encountered?
   increased or decreased? □Yes □No □Unsure
   10 years? □Yes □No □Unsure

APPENDIX C SUPERVISOR SELECTION QUESTIONNAIRE

Interview Questionnaire for Selection of Supervisors

Landing Site OR Vessel Name:_____ Date:__/___/2019

Name: _____ Telephone No: _____

1. How old are you?
   □ ≤17 □18-29 □30-39 □40-49 □ 50-59 □≥60
2. What is your highest level of education?
   □ Primary □ Secondary □ Tertiary
3. Are you currently employed? □Yes □ No
4. What is your occupation? _____
5. What is your current address?
   _____
6. Do you have any experience working in the fishing industry? □Yes □No
7. Please describe your experience in the industry:
   _____
   _____
   _____
8. Are you familiar with the fishermen working at this site? □Yes □No
9. Are you able to identify the different types (species) of fish? □Yes □No

   Can you identify these fishes?

_____

10. Do you have any physical problems that would prevent you from doing the work?

11. Have you ever used a camera before? □Yes □No

12. Are you willing to help in collecting data on fishing activities for which you will be trained and given a stipend? □Yes □No

13. Will you be available to do this for at least 6 months? □Yes □No

APPENDIX F SMITH'S CREEK AND MORAHWANNA (REGION 1)

1 LANDING SITE OVERVIEW

Smith's Creek is a village along the Barima River approximately 14 kilometers from the town of Mabaruma. The primary livelihood activity is fishing. The neighboring village of Morahwanna is one of the largest fishing landing sites in Region 1 and has docking capacity for large fishing vessels.

Fisherfolk estimate that approximately six artisanal vessels operate regularly from this site, although up to 20 vessels from both Smith's Creek and the neighboring community of Morahwanna dock at both sites at any one time. All vessels are equipped with outboard engines ranging in size from 15 to 48 horsepower (hp). Drift seines are used by the two vessels with engine sizes of more than 40 hp. Mesh sizes range from 2.5 to 18 centimeters (1 to 7 inches). Vessels operating the 15 hp engines use pole seines with mesh sizes of 9 centimeters and 20 centimeters (3.5 and 7.9 inches). A few fisherfolk also use pin seines and Cadell lines.

As a result of these varied methods, no target species was identified during the study, and the most abundant species caught was cuirass, which can be caught using any of the seine mesh sizes used at this landing site. Hauls also included jewfish and string rays (endangered, threatened, and protected species), and shark species, some of which may be considered endangered, threatened, and protected, or vulnerable species. In total, 36 different commercial species of fishes were caught with a total weight of 80,830 kilograms (178,200 pounds).

Vessels with engines of more than 40 hp generally make one trip per week, spending 5 to 6 days at sea per trip. Fishing occurs at 11 meters (36.1 feet) depth with soak time for fishing activities lasting approximately 3 to 5 hours. The 15 hp vessel also makes one trip per week spending up to 5 days fishing in the Waini region.

According to the fisherfolk at the landing site, the main challenge they experienced during the study was high fuel prices that occasionally made fishing trips economically unfeasible. High fuel prices reduced the economic viability of fishing as a livelihood activity for villagers of Smith's Creek. The regional supervisor indicated that fishing activities were significantly curtailed particularly in the May to July 2019 period. The regional supervisor explained that fuel used by fisherfolk in Smith's Creek was imported from Venezuela. As a result of the socioeconomic crisis in Venezuela, fuel imports declined resulting in a shortage that in turn significantly increased prices. Before the shortage, expenses per fishing trip were mainly related to purchasing fuel typically costing approximately $20,000 GYD ($96 USD). During the shortage, fuel prices were reported to be routinely at least twice as high as before the fuel shortage. In response to the shortage, the government-owned Guyana Oil Company Limited (GuyOil) increased the sale of fuel in Mabaruma. However, fisherfolk reported that these prices were also higher than prices before the shortage and that supply is often inadequate to satisfy all consumers. As of January 2020, many fisherfolk had resumed fishing, but fuel prices remained high.

Fisherfolk at this location indicated that they are affected by pirates from Venezuela and allegedly are victims of theft. When pirates attack fisherfolk at sea, the pirates rob them of engines, seines, hauls, and in some cases vessels. In extreme instances, pirate attacks result in loss of life. During the study period, neither the regional nor the onboard supervisors reported any piratical attacks.

2 REGIONAL SUPERVISOR RESULTS

One regional supervisor was selected to participate in the study. Due to the fact that Smith's Creek is an Amerindian community, the Toshao (local Amerindian leader) was engaged to assist in selecting the supervisor.

2.1 Effort and Haul

Over the May 2019 to January 2020 period, the regional supervisor collected data from 45 hauls from Smith's Creek and 164 hauls from the Morahwanna landing sites. In addition, data were also collected from 42 hauls at the Kumaka Wharf in Mabaruma as vessels from Smith's Creek and Morahwanna villages travel directly to that site on market days to sell their haul. A very high diversity of commercially viable fishes are caught and there are markets for all species, including stingrays that are sold locally or exported to Venezuela. At most other landing sites in the study, species like stingrays would not be considered commercial catch and are likely classified as a bycatch and released at sea or discarded. The majority of fishes caught by the fisherfolk from the Smith's Creek village are sold at the Kumaka Market in Mabaruma.

Vessels typically fish at the mouths of Waini River and Barima River at depths of approximately 8 meters. The effort expended on fishing activities, measured by the average number of days spent at sea, varied throughout the year (Figure F-1). August, November, and December 2019 were the months during which the greatest effort was expended with fishing trips lasting, on average, for 5 days in August, and more than 5 days in November and December. The regional supervisor indicated that fisherfolk undertook longer fishing trips, instead of several shorter trips, in response to the increased fuel prices as a measure to reduce fuel consumption. The greatest effort expended in November and December may also be associated with fisherfolk beliefs that this period is part of the off-peak fishing season, referred to locally as the hard season, in which fishes are least abundant and therefore greater effort is required to catch economically feasible hauls. According to the regional supervisor, preferred fishing grounds change seasonally and during off-peak seasons, fisherfolk are likely to travel farther offshore to fish.

In May 2019, fisherfolk expended the lowest level of effort and this may also be linked to fewer fishing trips due to the increased fuel prices. In addition, the variances in the duration of fishing trips on a monthly basis were likely influenced by a variety of factors including fishing practices, based on engine size and gear type, and increased fuel prices. For example, in June and July 2019, the months with the lowest average productivity, the longest fishing trip duration was 10 days. By contrast, in October 2019, the month with the highest average productivity, the longest was 8 days.

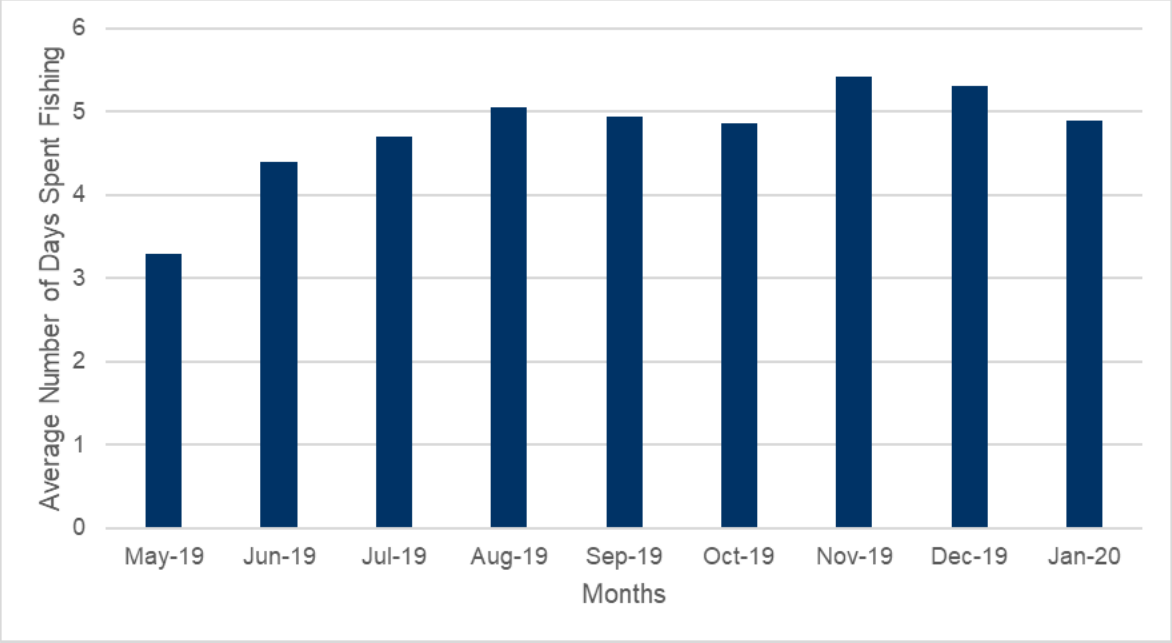

Figure F-1: Average Fishing Effort per Month at Smith's Creek and Morahwanna

2.2 Target Species and Diversity

Based on the data collected, 36 different commercial species of fishes were caught with a total weight of 80,830 kilograms (178,200 pounds). When fuel prices are consistently lower, the total weight of landed fishes would likely be even greater because more fisherfolk are expected to conduct fishing activities more frequently. As seen on Figure F-2, cuirass was the most abundant fish caught by weight with 9,875 kilograms (21,771 pounds). This may be because cuirass stays relatively close to estuaries where the fishing activities are carried out and can be caught by all seine types used. Bangamary, snook, and trout were the second to fourth most abundant species caught by weight with 8,618, 7,813, and 7,071 kilograms (18,999, 17,225, and 15,589 pounds), respectively. These were the only four species for which total haul weights exceeded 6,000 kilograms (13,228 pounds). Some fisherfolk from whom data were collected target bangamary by using drift seines with mesh sizes of 2 inches (5 centimeters) to 4 inches (10 centimeters). Trout and butterfish were also caught in relatively large numbers by individuals targeting bangamary; this phenomenon was also observed at other landing sites where bangamary is targeted such as Riverview (Region 4) and Mahaicony Bridge (Region 5).

Snapper, one of the highest-value species in Guyana, was the fifth most abundant species caught by weight with 5,890 kilograms (12,985 pounds). Snapper is targeted by some fisherfolk at Smith's Creek who use drift seines with larger mesh sizes in particular with mesh sizes of 7 inches (18 centimeters). Snapper is sold primarily for meat and unlike other landing sites, the glue (swim bladder) is not high value as there is no local demand or easy access to other markets. However, fisherfolk were aware of the value of the glue at other landing sites and some indicated that they have traveled to the Charity landing site in Region 2 to sell the glue harvested from snapper and trout.

This landing site is one of only three landing sites at which jewfish were caught. Hauls including jewfish were reported in May, September, October, and December 2019 and January 2020 by fisherfolk who were fishing at the mouths of the Waini and Barima rivers. In total, 58 kilograms (128 pounds) of jewfish were caught, although fisherfolk do not target this species. It is not known whether jewfish is typically caught in these waters during these months and further research is needed to determine whether this may be linked to any particular behaviors, such as spawning or feeding behaviors, of this fish. Shark were caught in greater abundance than jewfish, but were not identified by species and as such, it cannot be determined whether any of the fishes caught are endangered, threatened, or protected species.

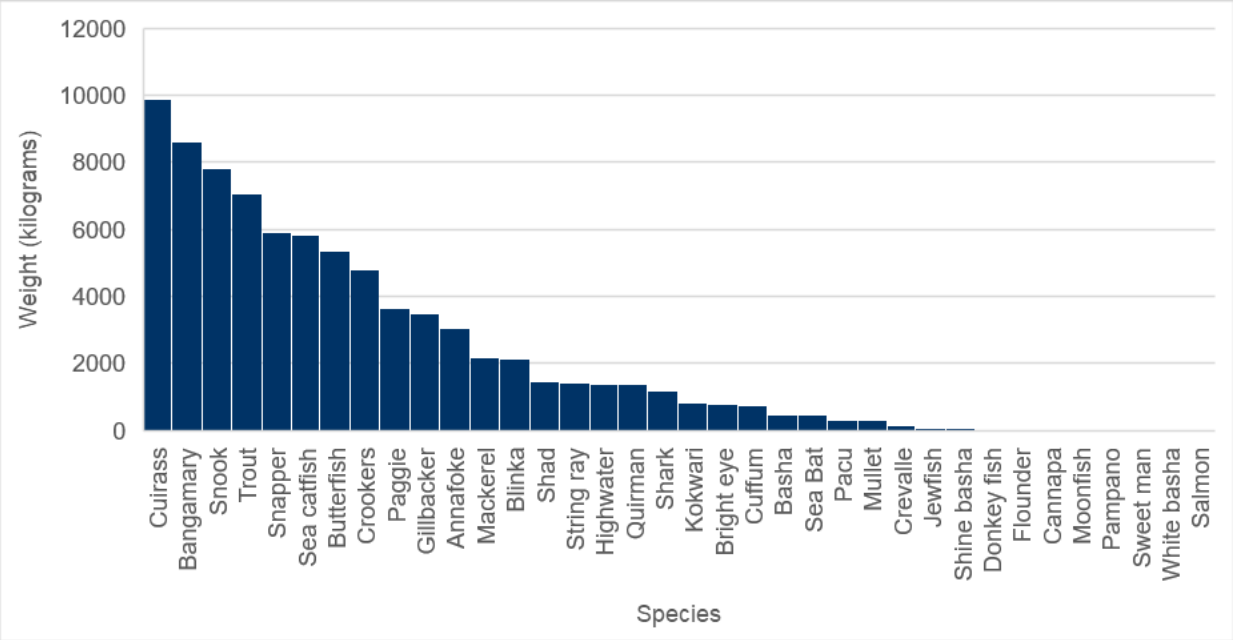

Figure F-2: Total Weight of Species Caught at the Smith's Creek and Morahwanna

Diversity of commercially viable species recorded at this landing site was the second highest compared to data collected by the other regional supervisors. Species diversity of hauls varied throughout the year and October had the highest diversity of commercially viable species with 32 different species caught (Figure F-3). One of the reasons for this high diversity may be the result of fisherfolk intersecting migratory fish species such as pampano and moonfish that migrate from North America in the months of September and October. May was the second most diverse month with 31 species caught; this may be due to increased nutrient flow at the mouth of the Waini and Barima rivers where more fishes come to feed and therefore are the preferred fishing grounds at this time of year. By contrast, June and August were the months in which the lowest species diversity was recorded.

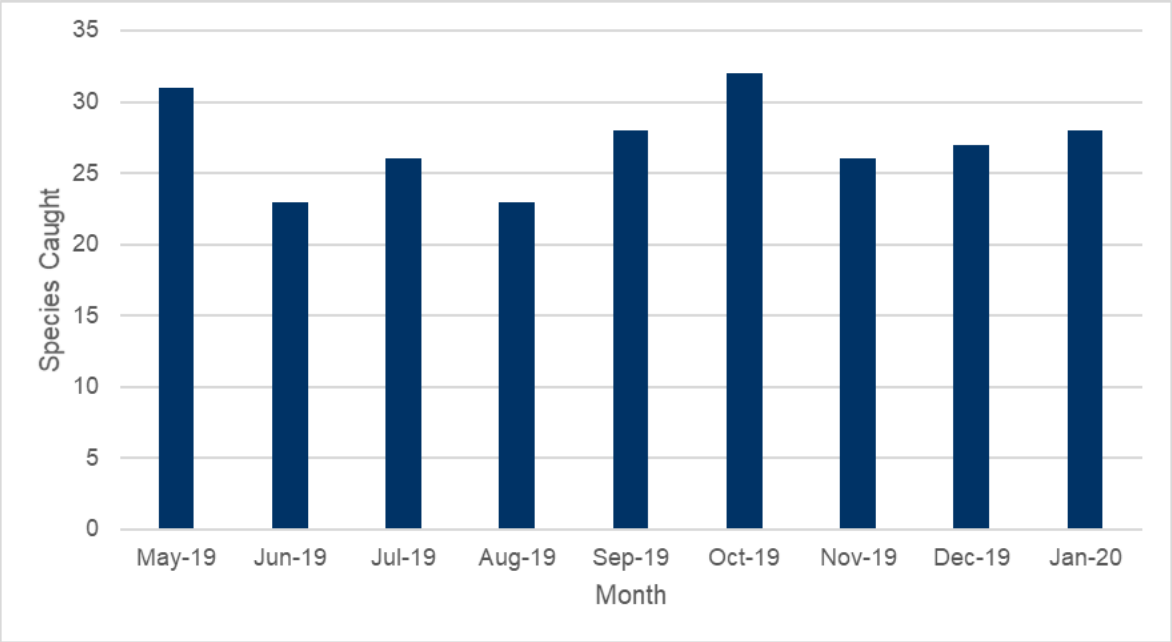

Figure F-3: Species Diversity at the Smith's Creek and Morahwanna

2.3 Seasonal Productivity

Average monthly productivity of fishing trips, measured as total monthly haul weights divided by the number of fishing trips, also varied on a monthly basis (Figure F-4). Artisanal fisherfolk in Guyana have a shared belief of the seasonal productivity of fishing activities, which influenced their fishing practices, in particular the effort expended. The peak fishing season, commonly referred to as the good" season, is believed to occur during periods of the year when waters are warmer (which may lead to an abundance of fishes) and calmer (which is less dangerous and requires less effort to fish). As such, the good season purportedly starts in May but peaks during the July to September. The hard season is typically considered the October to April period when waters become colder and rougher. However, these expected seasonal trends were not observed in the data collected by the regional supervisor. Instead, haul volumes appeared to be related to Guyana's wet and dry seasons. Specifically, seasonal variations in haul were observed along the following pattern:

- The May to July period, the primary wet season, had the lowest combined average monthly productivity of 247 kilograms (545 pounds). Overall, June and July were the least productive months and this may be attributed to a variety of factors including high fuel prices, rougher waters, and less abundance of fishes closer to the shorelines.
- The August to October period, the primary dry season, had the highest combined average monthly productivity of 382 kilograms (842 pounds). Overall, October (the month during which the hard season is expected to start) was the most productive of the study period.
- The November to January period, the secondary wet season, had a combined average monthly productivity of 347 kilograms (765 pounds). This productivity is significantly higher than what was observed during the May to July period. However, fisherfolk expended more effort in the November to January period (as seen on Figure F-1) that may partly account for the increased productivity.
- The secondary dry season occurs over the February to April period.

By comparison, in the May to September 2019 good season, the combined average productivity was 291 kilograms (483 pounds) while in the October 2019 to January 2020 hard season, the combined average productivity was higher with 369 kilograms (813 pounds).

However, these seasonal trends should be considered with caution. High fuel prices presented a significant confounding variable that curtailed normal fishing practices, particularly in June and July 2019. Further data are required to determine whether the trends observed thus far can be representative of practices that generally prevail at Smith's Creek and Morahwanna.

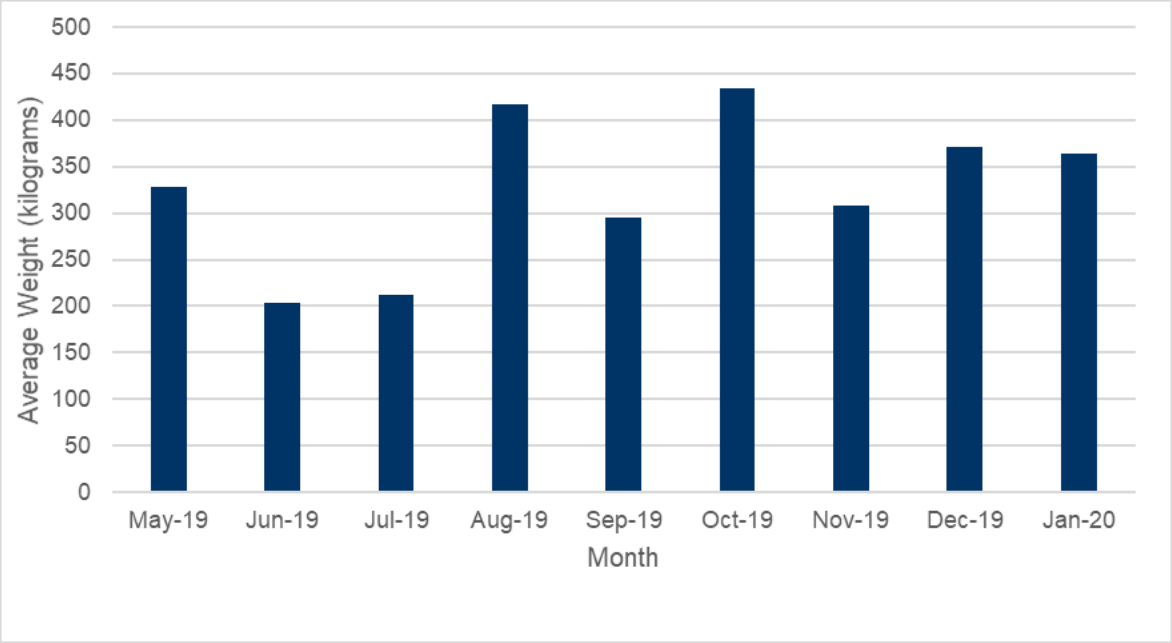

Figure F-4: Average Monthly Productivity of Fishing Trips at Smith's Creek and Morahwanna

2.4 Prices and Markets

Cannapa was the highest-value fish during the study with an annual average price per kilogram of $551 GYD ($2.6 USD) per kilogram as seen on Figure F-5. Cannapa is rarely caught and was only recorded for one landed vessel at Morahwanna in January 2020 and this may have accounted for the high price at which it was sold. Gillbacker and snapper were the second and third highest-value fishes with annual average prices per kilogram of $544 GYD ($2.60 USD). Gillbacker and snapper are typically the highest-value commercial species and this is similar to trends at other landing sites included in the study. However, unlike most landing sites, annual average prices of gillbacker were higher than those of snapper. At most other landing sites, snapper was consistently more highly valued than gillbacker due largely to the loss of the U.S. export market for gillbacker in 2018 after the United States Department of Agriculture (USDA) banned the import of catfishes and catfish products from Guyana because local food safety inspection systems were not equivalent to U.S. inspection systems. Annual average prices per kilogram for all other species, including trout, were less than $500 GYD ($2.39 USD). Based on the data collected by the regional supervisor, fish sales from this landing site totaled $26,721,374 GYD ($127,853 USD). The jewfish was an upper middle-value fish with a cost of $331 GYD ($1.60 USD) per kilogram.

By contrast, the annual average price per kilogram was less than $100 GYD ($0.48 USD) for four species, namely flounder, sweet man, moonfish, and donkey fish. These species are not high value and do not have a high demand.

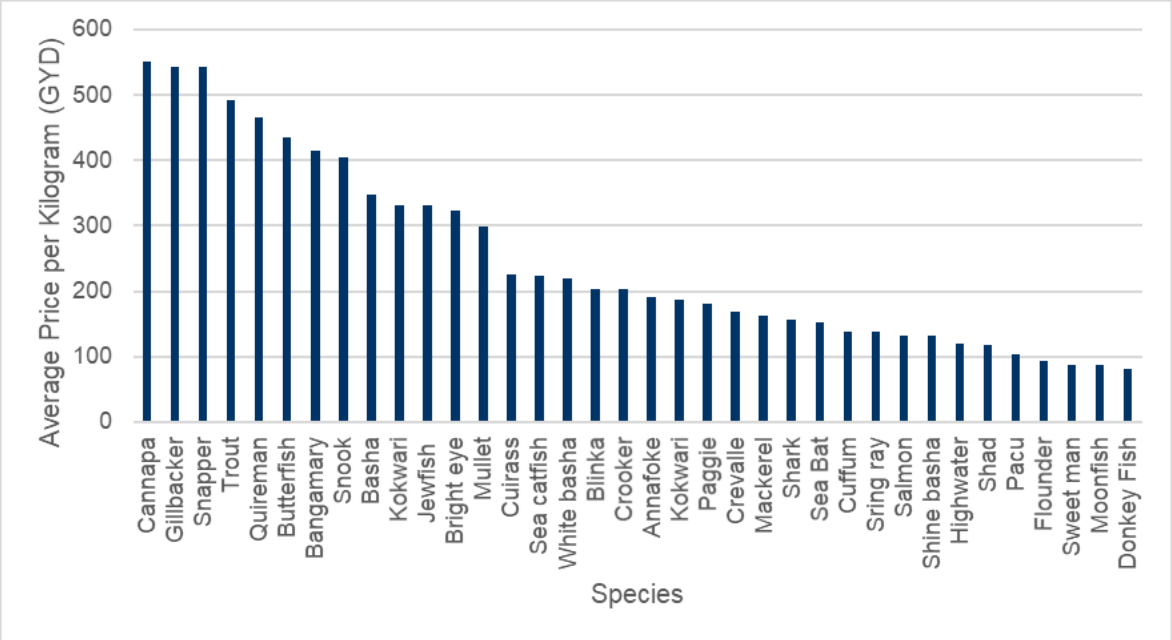

Figure F-5: Annual Average Prices per Kilogram of Fishes at Smith's Creek and Morahwanna

Three of the most abundant species caught, bangamary, snook, and trout, were priced in the upper mid-range value with annual average prices per kilogram of $415 GYD ($2 USD), $405 GYD ($1.90 USD), and $492 GYD ($2.40 USD), respectively. Cuirass, which was the most abundant species caught, was priced in the lower mid-range value with an annual average price per kilogram of $225 GYD ($1 USD). However, there were variations in prices for all species based largely on the interplay of demand and supply. Figure F-6 shows the minimum, maximum, and average monthly prices for the four most abundant species caught. Over the course of the study, maximum prices for cuirass, snook, and trout peaked in August and September 2019 and this was attributed primarily to the concomitant peak in fuel prices. The increase was most drastic for cuirass for which maximum prices rose two-fold from the typical maximum prices. Similarly, minimum prices were highest in August and September 2019 and the December 2019 to January 2020 periods. In some instances, the difference between the minimum and maximum prices for these periods was negligible. The higher minimum prices in August to September 2019 were also attributed to the high fuel prices. These trends demonstrate that the increased expenses borne by fisherfolk were ultimately passed on to the consumers in the form of high prices and it is likely that this practice also holds true for other high-demand species such as snapper, gillbacker, and butterfish.

Higher prices were also observed for bangamary, cuirass, and snook in December 2019 and January 2020. However, it should be noted that some fishes are more highly valued at this landing site than other landing sites included in the study. For example, maximum prices for bangamary were consistently greater than $600 GYD ($2.90 USD) per kilogram at Smith's Creek, which is higher than maximum prices reported by other regional supervisors and more than twice the maximum prices reported at Riverview (Region 4) and Mahaicony Bridge (Region 5) where bangamary is the target species. Similarly, at this landing site the maximum price for trout was greater than $1,200 GYD ($5.74 USD) per kilogram and was

significantly higher than other landing sites where trout is one of the primary target species like Charity (Region 2), Riverview (Region 4), and Mahaicony Bridge (Region 5).

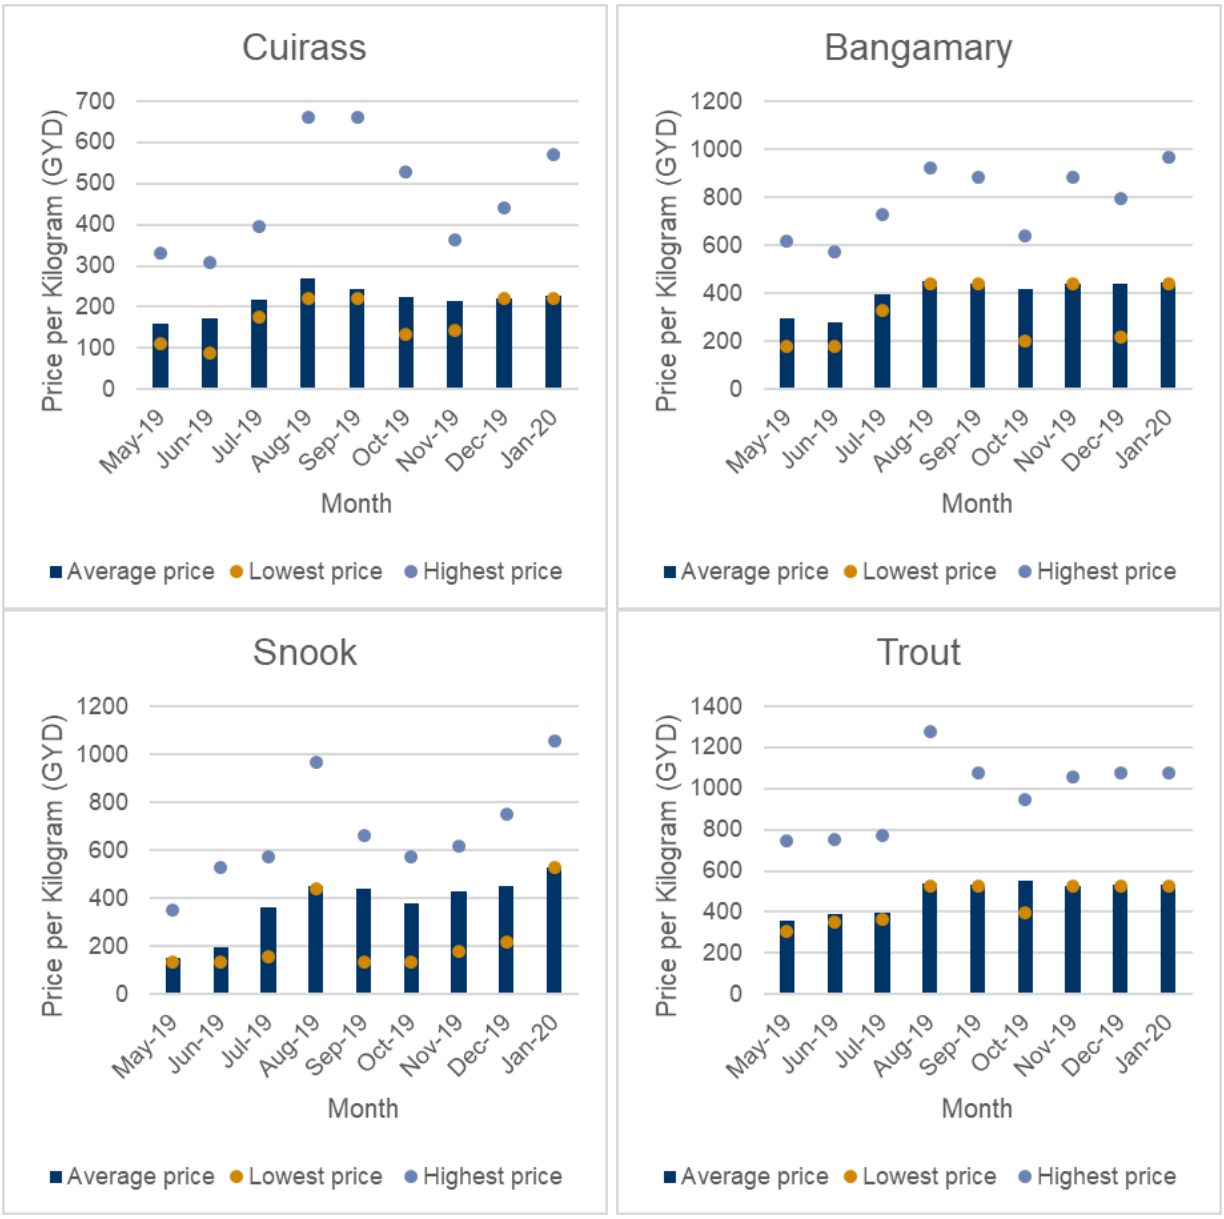

Figure F-6: Monthly Price Variations of the Four Most Abundant Species Caught

2.5 Biometrics

The regional supervisor measured the lengths and weights of fishes that were representative of hauls for which data were collected. Due to the large diversity of fishes, it was difficult for the supervisor to take the biometric data from all species per haul. Figure F-7 shows the annual average lengths and weights of fishes that were measured during the study. The smallest fish recorded was annafokes at 24.5 centimeters and 680 grams, and at this size, annafokes have reached sexual maturity. In addition, it is unlikely that smaller fishes, of any species, would be caught by fisherfolk using this landing site because mesh sizes are generally not less than 2 inches (6 centimeters). On the whole, the majority of

the fishes measured at this landing site had achieved sexual maturity including high-value species like gillbacker, snook, bangamary, and rare species like cannapa. However, juvenile fishes were also caught. For example, although jewfish was the largest fish caught, it was juvenile for its species with an average length of 77 centimeters and weight of 13,380 grams compared to sexually mature jewfish, which are generally 273 centimeters in length and 383,000 grams in weight. Similarly, snapper, one of the highest-value fishes at this landing site achieves mature weights of up to 15,000 grams and the average weight of fishes measured were significantly lower.

The annual average lengths of fishes measured for the four most abundant species caught indicate that these fishes had reached sexual maturity. However, comparisons of monthly average lengths and weights of these species for the months in which they were measured (Figure F-8) displayed the following trends. Juvenile bangamary, cuirass, and trout were representative of these species in hauls in May 2019, but biometrics measurements were not taken for snook in this month. Monthly average lengths of bangamary from June 2019 onward indicated that these fish had reached sexual maturity. The largest cuirass and trout were caught in August and September 2019. Snook caught in July and August 2019 were also sexually mature. The July to September period is widely believed to be the spawning periods for these fishes and females caught are frequently carrying eggs, which contributes to larger fishes being caught at this time of the year.

When the spawning period ended, smaller fishes caught were cuirass, snook, and trout. A particularly sharp decline in the size of trout and snook was observed in October 2019 when the measured fishes were juveniles. From November 2019, fishes were once again larger and sexually mature. This cycle of larger fishes being caught in spawning season, smaller fishes being caught after the spawning season, and then a subsequent uptick of sizes is likely to be seen in most of the other commercially viable fish species that exhibit similar reproductive behaviors.

Figure F-8: Monthly Average Lengths and Weights of Most Abundant Species Caught

3 ONBOARD SUPERVISOR RESULTS

Three onboard supervisors were selected at various stages of the study to participate and the Toshao was engaged to assist in selecting the supervisors. Due to the fuel shortage experienced in the region, the onboard supervisor initially selected by the Toshao in April 2019 had ceased all fishing activities by May 2019 and had not resumed fishing by October 2019 and so no data collection from an onboard supervisor occurred during this period. Following further engagements with the Toshao, this supervisor was replaced by two new onboard supervisors (to compensate for the previous period when there was no data collection) who continued commercial fishing activities despite the fuel shortage and collected data commencing November 2019.

Both new onboard supervisors used drift seines with mesh sizes of 2.5, 5, 7.5, 10, and 12.7 centimeters (1, 2, 3, 4, and 5 inches) on an alternating basis while fishing. However, there are some key differences between the two vessels:

- Vessel A is the larger of the two vessels and the target species is sea bats. The vessel has a haul capacity of 3,000 kilograms (6,600 pounds) and is powered by a 40 hp engine. Each fishing trip requires a five-member crew and trips typically last for 6 days. This vessel usually travels approximately 10 kilometers offshore to fish at depths of 18 meters. The main expense per fishing trip is for fuel that is required to facilitate long trips. All sea bats caught are sold to vendors for export to Venezuela, while other fishes were sold to local vendors in Region 1.

- Vessel B has a haul capacity of 1,000 kilograms (2,200 pounds) and is powered by a 15 hp engine. This vessel has no specific target species. Each fishing trip requires a three-member crew and trips typically last for 4 days. This vessel usually travels approximately 5 kilometers offshore to fish at depths of 11 meters. The main expense per fishing trip is for fuel since ration for crew and ice for preservation of haul are not required on these shorter fishing trips. Hauls from this vessel are typically sold in local markets.

Apart from the high price of fuel, neither of the onboard supervisors encountered any other significant challenges during the study period that affected their fishing activities.

3.1 Fishing Area

All the data collected was from the hard season and therefore, unlike the analysis for other landing sites, fishing grounds cannot be analyzed for differences in fishing practices in the good versus the hard seasons. The main fishing area of both onboard supervisors, where most of the fishing points are clustered, is within a zone of 1,741 square kilometers (see Figure F-9). The fishing points were observed in three principal clusters:

- The first cluster of fishing points covered an area of 46 square kilometers and was located at the mouth of the Waini River and along the Region 1 coastline. These fishing grounds were used by both onboard supervisors and were located closest to the Smith's Creek village.

- The second cluster was located approximately 5 kilometers southeast of the first cluster. This cluster covered an area of 36 kilometers and these fishing grounds were also used by both onboard supervisors.

- The final cluster was located approximately 12 kilometers away from the second cluster and was comprised of only two fishing points. These fishing points covered a range of 151 square meters. This final cluster was only traversed by Vessel A, which was larger both in haul capacity and engine size and therefore could travel greater distances for trips.

Both vessels fished relatively close to the shoreline. The farthest distance traveled offshore was 11 kilometers, and this was done by Vessel B. The farthest Vessel A fished from the shoreline was 7.3 kilometers. In addition, Vessel B also fished closest to the shore with a fishing point of 0.22 kilometer.

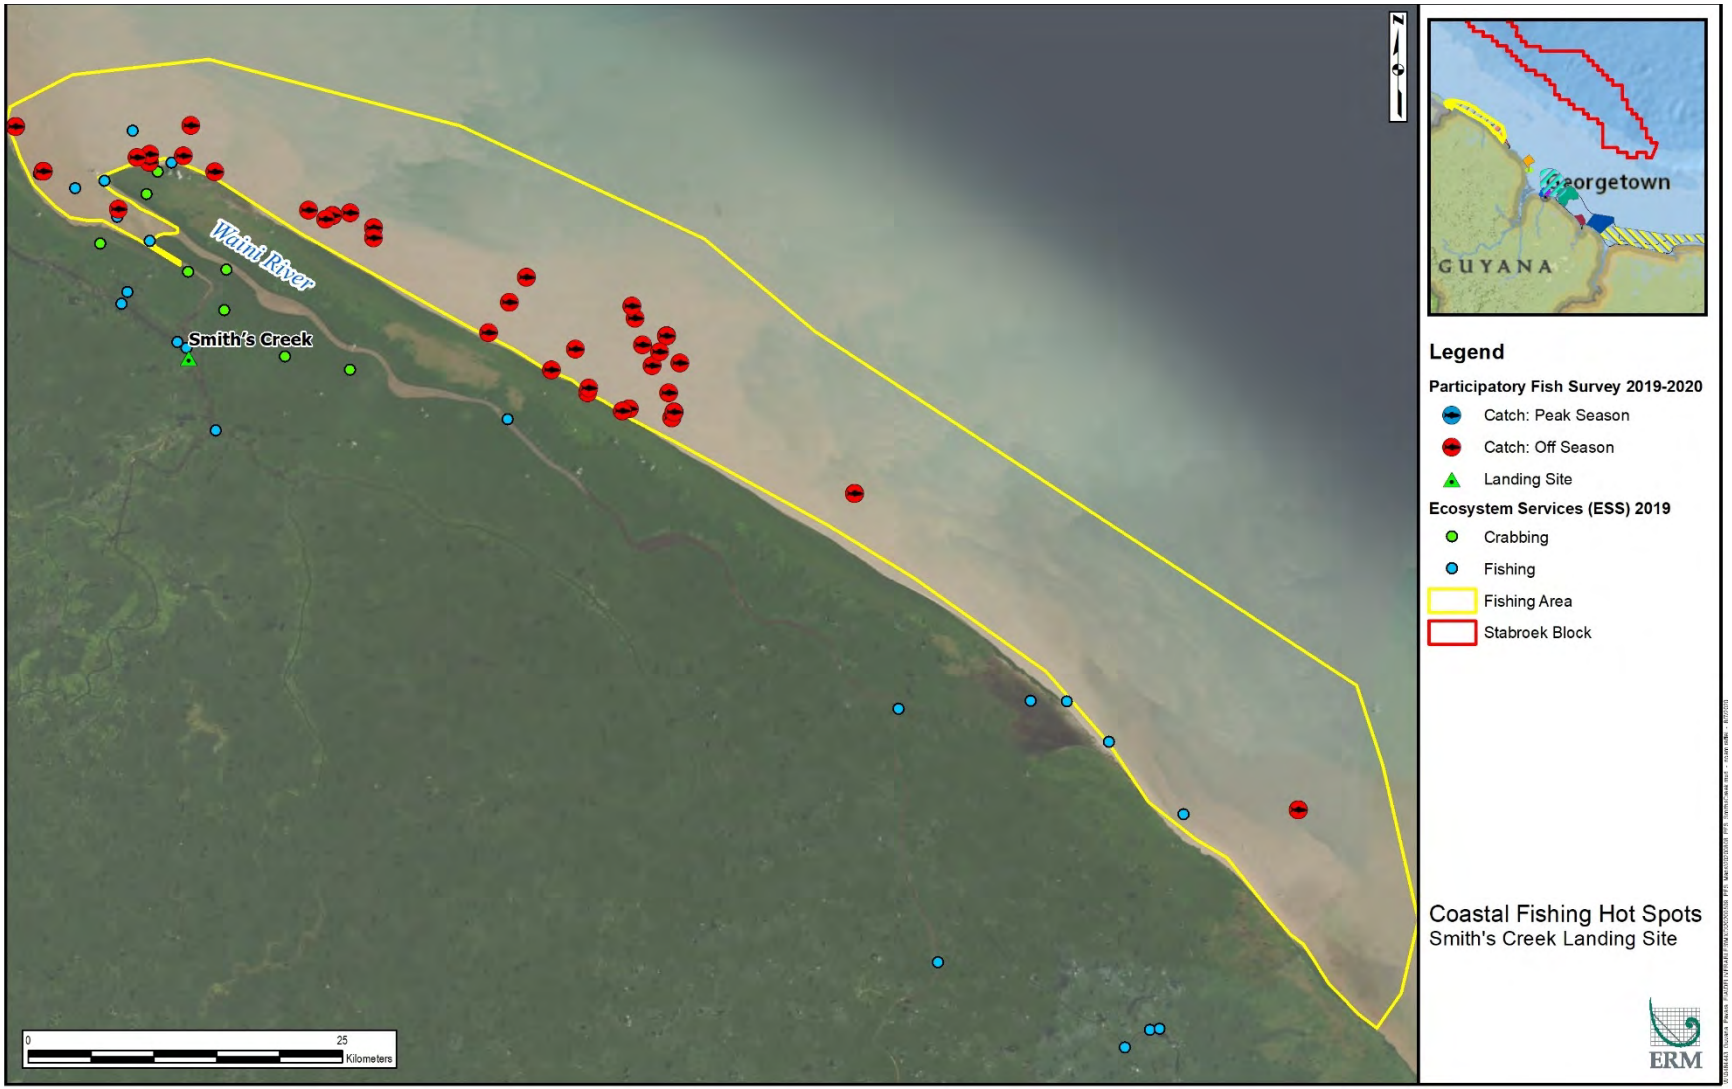

Figure F-9: Fishing Area and Fishing Points Used by the Smith's Creek Onboard Supervisors

3.2 Effort and Haul

As shown on Figure F-10, the total weight of combined hauls from Vessel A over the November 2019 to January 2020 period was 19,813 kilograms (43,680 pounds). The most abundant species caught was the sea bat accounting for 36 percent of the total haul with 7,148 kilograms (15,758 pounds). The supervisor indicated that this species is targeted because of lucrative export markets to Venezuela. Hauls are sold to trawl vessels that dock in the Barima River and transport the produce to Venezuela for sale where sea bats are reportedly considered a high-value species. The second to fourth most abundant species caught was paggie, annafokes, and basha. Among the supervisor's hauls were cuirass, snook, and trout, which are among the most abundant species caught reported by the regional supervisor, and snapper, which was the second most high-value species. Shark was also caught by this onboard supervisor, but the species were not reported, so it cannot be determined whether they are considered an endangered, threatened, protected, or vulnerable species. Overall, 12 species were caught by the onboard supervisor. No bycatch was reported by the onboard supervisor.

The total weights of combined hauls from Vessel B over the November to December 2019 period was 3,511 kilograms (7,740 pounds). The two most abundant species caught were snapper and cuirass accounting for 7.6 percent and 6.6 percent of the total haul, respectively. This is consistent with the data collected by the regional supervisor who also recorded snapper and cuirass as some of the most abundant species caught. Moreover, like the regional supervisor, the catch composition does not demonstrate that there was any target species and this suggests that seines with a variety of mesh sizes were used. The haul included gillbacker, which is the highest-value fish at this landing site and bangamary, which is also highly valued in local markets. Overall, 14 species were caught by the onboard supervisor. No bycatch was reported.

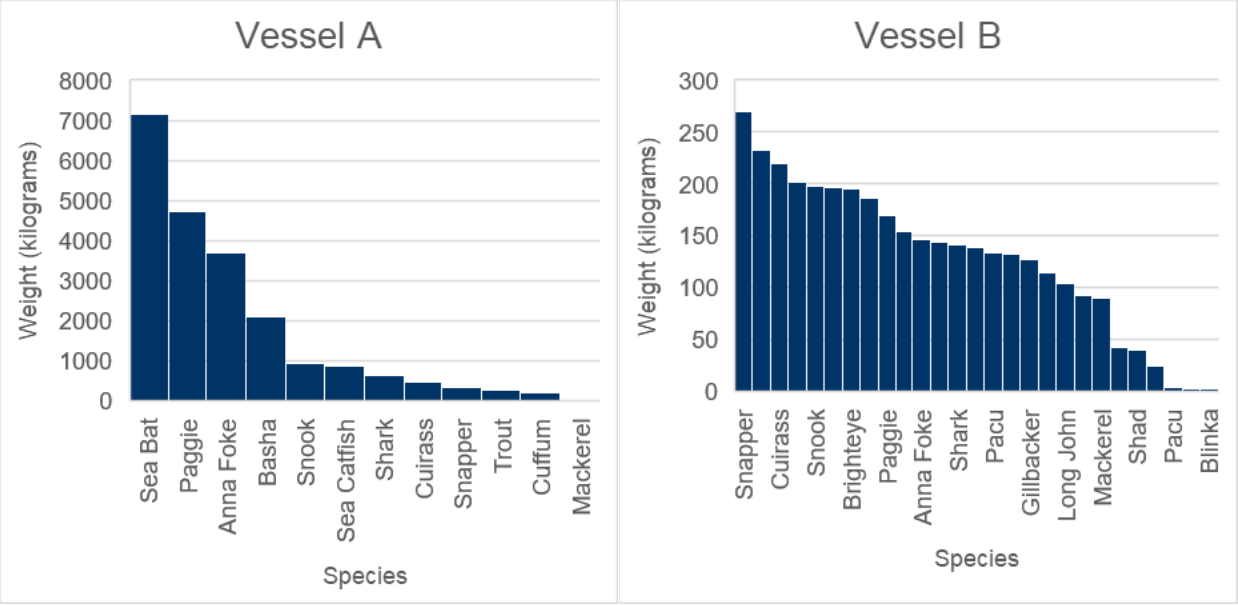

Figure F-10: Total Weight of Species Recorded by Vessel A at the Smith's Creek Landing site

Based on the data available, Vessel B consistently expended greater effort on fishing activities (Figure F-11). In November 2019, Vessel B spent 444 hours fishing compared to 120 hours for Vessel A and similarly, in December 2019 Vessel B spent 480 hours fishing compared to 432 hours for Vessel A. However, as seen on Figure F-12, total hauls from Vessel A were significantly higher than Vessel B from

November to December 2019. Moreover, for Vessel A, average weight of hauls per soaking consistently increased over the November to January 2020 period, whereas for Vessel B there was a decline in December:

- In November 2019, Vessel A had a total haul of 1,948 kilograms (4,294 pounds) with an average weight of hauls per soaking of 244 kilograms (538 pounds). By contrast, the productivity of Vessel B was lower with a total haul of 1,787 kilograms (3,939) pounds with an average weight of hauls per soaking of 48 kilograms (106 pounds).
- In December 2019, Vessel A had a total haul of 17,865 kilograms (39,385 pounds) with an average weight of hauls per soaking of 687 kilograms (1,514 pounds). By contrast, the productivity of Vessel B was significantly lower with a total haul of 1,724 kilograms (3,800 pounds) with an average weight of hauls per soaking of 43 kilograms (95 pounds).

These vessels share the fishing grounds in the Waini and Barima rivers and the differences in productivity are attributed principally to the fishing practices, gear used, and haul capacities of the vessels. By virtue of its larger engine, Vessel A travels more quickly to preferred fishing grounds and can also access fishing grounds farther offshore. This may have been particularly beneficial to Vessel A during the study period because November and December are typically considered part of the hard season and fisherfolk modify their fishing practices by traveling farther offshore to fish. In addition, quicker transits to fishing grounds may have contributed to lower effort being expended by Vessel A, particularly in December 2019 when Vessel A had spent 432 hours fishing and Vessel B 480 hours. However, it should also be noted that total hauls from November to January 2019 were relatively high based on the data collected by the regional supervisor, but this may be attributed to fewer routinely conducted fishing trips due to the fuel shortage.

Moreover, Vessel A also has greater haul capacity that allows each fishing trip to be more productive by both having longer fishing trips and transporting greater haul volumes to market. For example, the average weight of hauls per soaking for Vessel A was 857.5 kilograms (1,890 pounds) and based on its haul capacity this vessel could transport 3,000 kilograms and at least three such hauls. However, Vessel B had a haul capacity of 1000 kilograms and therefore could transport only one haul of such magnitude per soaking.

Finally, although both vessels use the same type of seines on an alternating basis, Vessel A likely used seines with smaller mesh sizes more frequently than Vessel B. This is likely due to sea bats being the target species of Vessel A. In instances where fishing grounds and effort are similar, as seen in December 2019, increased productivity of Vessel A was likely due to using seines with smaller mesh sizes, which captured more of the species passing through it compared to Vessel B.

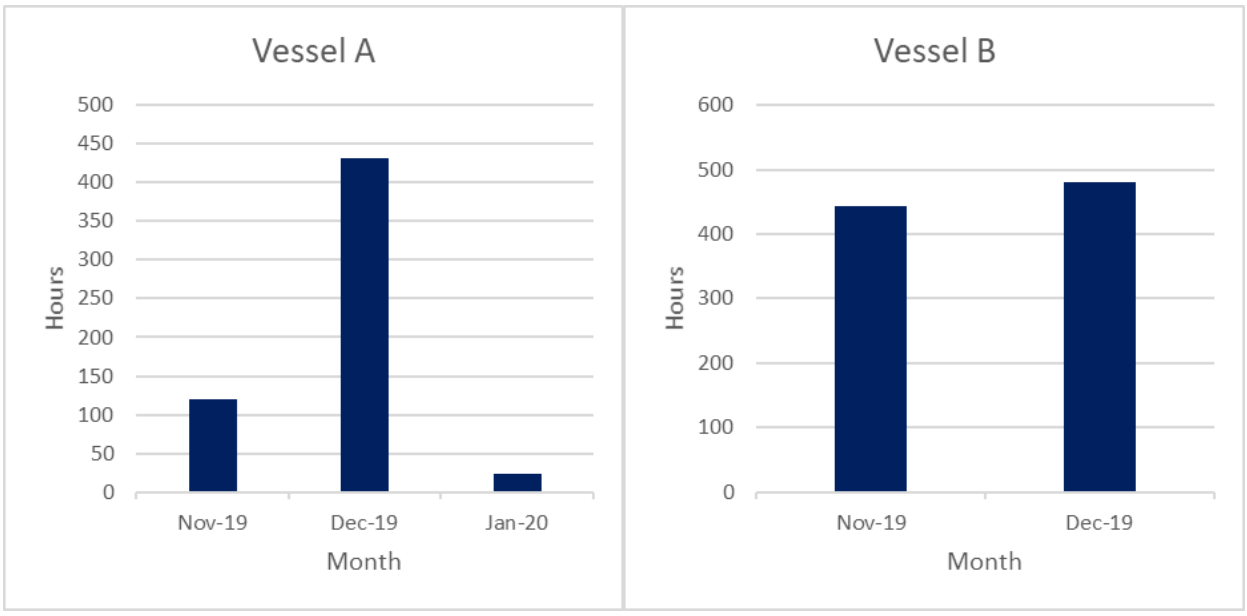

Figure F-11: Total Effort Recorded by the Smith's Creek Onboard Supervisors

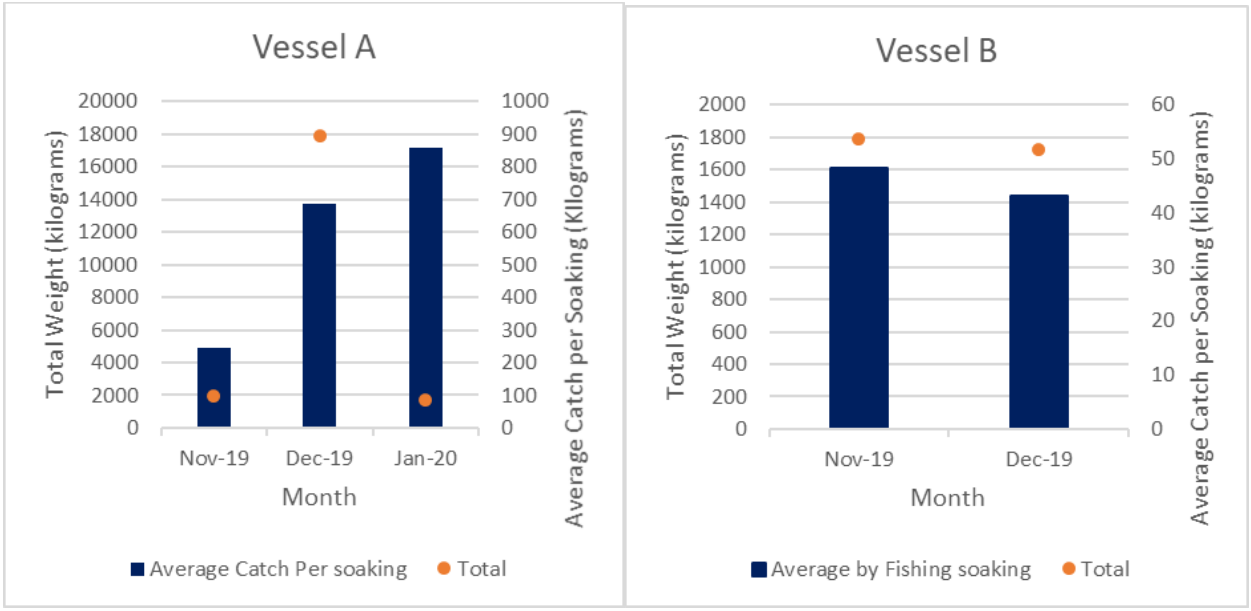

Figure F-12: Total Monthly Weight and Average Weight per Soaking of Hauls Recorded by the Smith's Creek Onboard Supervisor

3.3 Seasonal Productivity

Due to the relatively small data sets for these onboard supervisors, seasonal trends cannot be ascertained. Moreover, the November and December 2019 data sets for Vessel A are incomplete because the onboard supervisor is currently clarifying data collected during February and November.

3.4 Biometrics

Based on the lengths and weights of fishes measured by the onboard supervisors (Figure F-13), all species caught by the onboard supervisor of Vessel B had achieved sexual maturity. However, the average lengths and weights of the sea bats, the most caught species by weight, and annafokes from Vessel A were juveniles. In particular, sea bats reach maturity at lengths of 64 centimeters, but those caught by Vessel A had average lengths of 12.7 centimeters. In instances where the same species were caught by both supervisors, the fishes caught by Vessel B were larger. For example, snapper caught by Vessel A had average lengths of 46 centimeters compared to 52 centimeters for Vessel B. Similarly, sea catfish caught by Vessel A had average lengths of 30 centimeters compared to 41 centimeters for Vessel B. Trout caught by Vessel B were also larger. This is directly attributable to the use of seines with smaller mesh sizes by Vessel A, which would only typically capture smaller fishes. Additional information is required to completely assess the differences in sizes of the species caught by the supervisors.

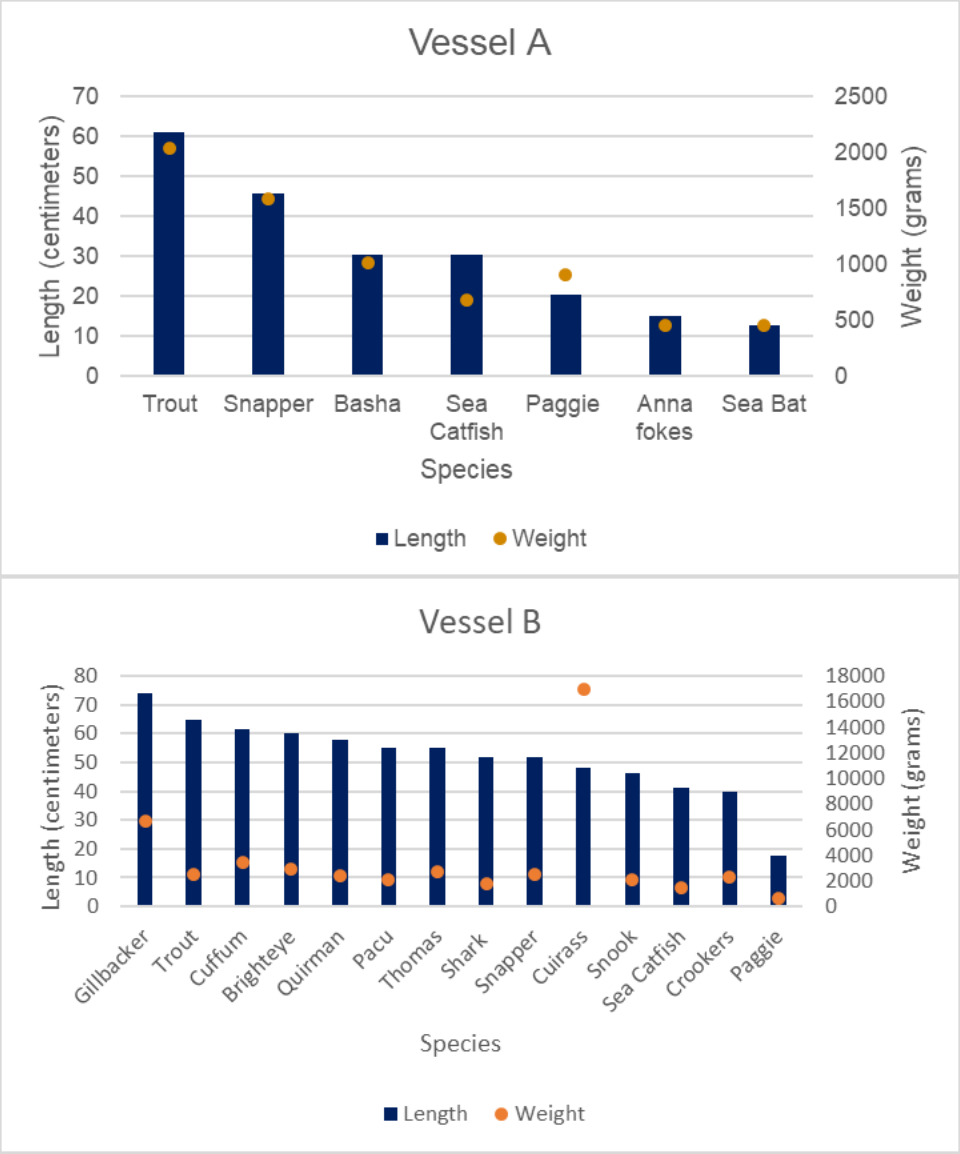

Figure F-13: Average Length and Weight of Fishes Caught by the Smith's Creek Onboard Supervisors

4 QA/QC DATA

4.1 Regional Supervisor

During the first QA/QC exercise, only one vessel (Vessel 1) landed at the Smith's Creek landing site. The vessel used drift seines with mesh sizes of 7.62, 10.16, 15.24, and 20.32 centimeters (3, 4, 6, and 8 inches). The fishing trip lasted for 4 days during which time the seine was soaked twice in an area called Crab Dog. The vessel used a 15 hp Yamaha outboard engine. The fisherfolk indicated that the high price of fuel was the most significant challenge experienced as it was challenging to make economically feasible fishing trips. These fishing practices and experiences were consistent with the fishing practices of fisherfolk from Smith's Creek reported by the regional supervisor. However, data were not collected by the regional supervisor from any vessels that fished in the Crab Dog area. Vessel 1 caught three species totaling 29.4 kilograms (65 pounds), consisting of bangamary at 9 kilograms (20 pounds), trout at 13.6 kilograms (30 pounds), and butterfish at 6.8 kilograms (15 pounds).

During the second QA/QC exercise, two landed vessels were assessed (Vessel 2 and Vessel 3) as seen on Figure F-14. Vessel 2 had a fishing trip lasting for 6 days at sea and made 12 soakings of a drift seine with mesh sizes of 5 centimeters (2 inches). This vessel used a 15 hp engine and traveled to Venezuelan waters to fish. Vessel 2 caught three species totaling 231 kilograms (509 pounds) comprising quirman with 135.9 kilograms (300 pounds), cuirass with 68 kilograms (150 pounds) and gillbacker with 27 kilograms (60 pounds). Vessel 3 had a fishing trip lasting 3 days and used drift seines with mesh sizes of 8 centimeters (3 inches) as well as Cadell lines. The fishing gear was soaked once and the Vessel traveled to the Waini River mouth to conduct fishing activities. Vessel 3 also caught three species, totaling 81 kilograms (179 pounds) which was comprised of high water at 45.3 kilograms (100 pounds), snook at 22.7 kilograms (50 pounds), and bangamary at 13.6 kilograms (30 pounds).

From the data collected by the regional supervisor, there is some variation from the overall catch. However, this may be attributed to the sizes of the vessels assessed, as all had engine sizes of 15 hp or lower, which indicates smaller vessel sizes. The supervisor recorded hauls from several vessels using engine sizes of 40 and 48 hp, which would be larger boats and would catch larger, more species-diverse hauls. A relatively low diversity is related to seine type.

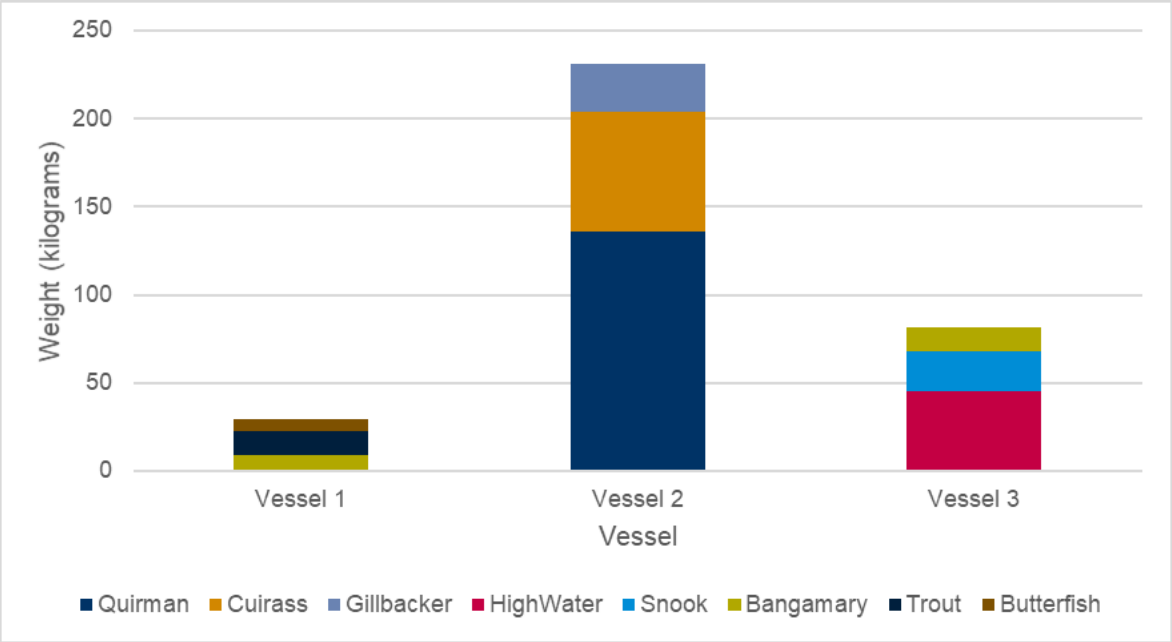

Figure F-14: Total Weight of Hauls Assessed during the QA/QC Exercises

Vessel 1 sold its haul at the following prices: $661 GYD ($3.2 USD) per kilogram of bangamary; $661 GYD ($3.2 USD) per kilogram of trout; and $750 GYD ($3.6 USD) per kilogram of butterfish (Figure F-15). The species caught by the fishing trip assessed were among the most abundant species caught in the collective hauls in the July to September period based on the data collected by the regional supervisor.

However, the prices recorded during the second QA/QC exercise varied from the prices recorded by the onboard supervisor. For example, Vessel 3 sold snook for $661 GYD ($3.1 USD) per kilogram, but maximum prices recorded by the regional supervisor were $529 GYD ($2.5 USD) per kilogram. Two factors would have caused this variance. First, the QA/QC exercise was conducted at a local market where fisherfolk sell their hauls and this may have resulted in the price. Second, the vendors sell by pounds and conversion to price per kilograms would double the variance. If the price per pound were used, the cost variance would have been $46 GYD ($0.2 USD), compared to a variance of $132 GYD ($0.6 USD) based on the price per kilogram. This trend was seen for other species.

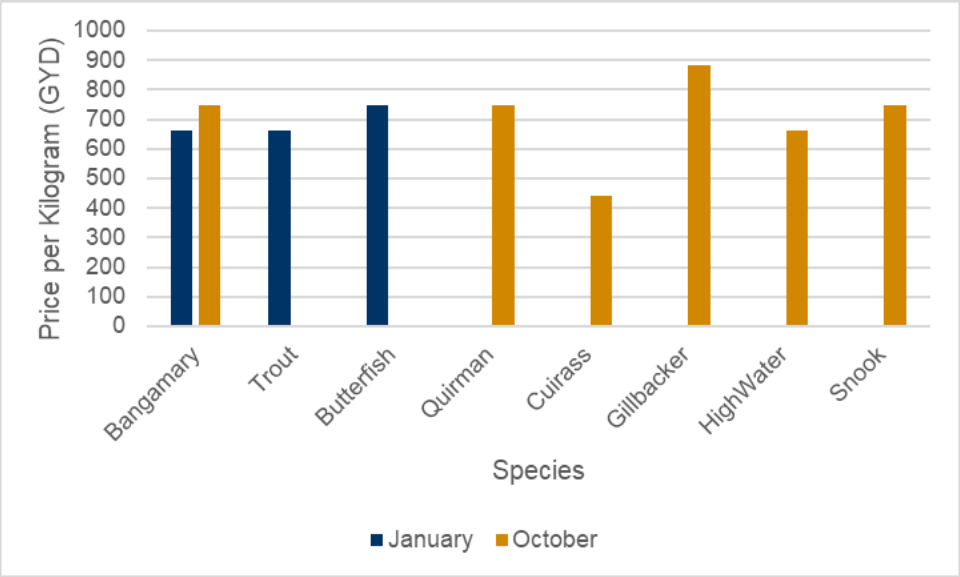

Figure F-15: Prices of Fishes Assessed during the QA/QC Exercises

Figure F-16 presents the lengths and weights of representative fished measured by the study coordinator during the QA/QC exercises. Although these fishes were smaller than the average lengths and weights of fishes measured by the regional supervisor, their sizes were consistent with the smaller fishes measured by the regional supervisor. Overall, the study coordinator was satisfied that the regional supervisor was thorough in collecting data from landed vessels and took accurate biometric measurements throughout the study program.

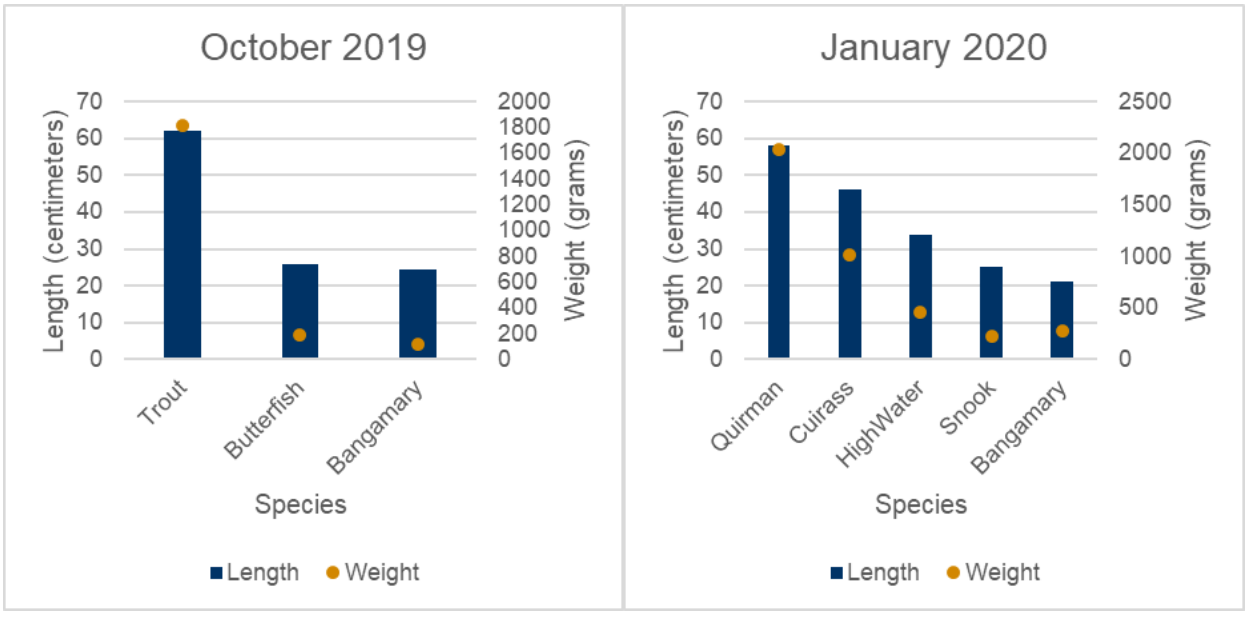

Figure F-16: Lengths and Weights of Fishes Measured during the QA/QC Exercises

4.2 Onboard Supervisors

The team did not get to conduct QA/QC exercise with the onboard supervisors. For Vessel A, the onboard supervisor's vessel did not return to the landing site as scheduled and therefore, the haul could not be assessed. Due to challenges scheduling meetings in Smith's Creek, the team collected data sheets for Vessel A from the onboard supervisor during his monthly visits to Georgetown. In addition, hauls from Vessel B were sold out when the study team arrived at the landing site and therefore could not be assessed.

APPENDIX G WARAMURI/HAIMOKABRA (REGION 1)

1 LANDING SITE OVERVIEW

Waramuri is an Amerindian community on the west bank of the Moruca River within the Moruca sub-district of Region 1. Haimokabra is considered a satellite village of Waramuri. Fishing is one of the most important livelihood activities in Waramuri/Haimokabra. Approximately 20 vessels normally operate from the landing site, all equipped with outboard engines ranging from 5 to 48 hp. Cadell (demersal long line) and drift seines with mesh sizes of 5 to 12 centimeters (2 to 4.7 inches) are the principal fishing gear used at this site.

Fisherfolk at this site use fishing grounds in several locations throughout Region 1 and 2 including Kamwatta, Moruca mouth, Pomeroon mouth, Iron Punt, Charo Beach, and Danfore. Engine size and fishing gear do not determine fishing practices, as both small and large vessels use either longline or drift seines and fish once per month, spending up to 14 days at sea per trip. However, one of the small vessels makes daily trips twice per week to the Moruca mouth for fishing.

Vessels typically fish between 3 to 16 kilometers from the coastline at depths of approximately 8 meters. Fishing trips range from 1 to 10 days. According to fisherfolk, the main species caught at this landing site are catfish, cuirass, snapper, trout, and gillbacker. Yield is typically 70 kilograms (154 pounds) of fish sold for approximately $600 to 800 GYD ($2.9 to 3.8 USD) per kilogram depending on species and season. Produce is sold at the Kumaka Market in Santa Rosa to vendors in the community, or transported by vendors to the Stabroek Market in Georgetown.

Ice is not readily available in this village, so fisherfolk have alternative preservation methods, like salting, smoking, or drying fish, during long fishing trips. To preserve the hauls, fisherfolk normally set up a camp on beaches along the Region 1 shoreline near their fishing zones and return to them daily with their catch to gut and salt the catch as a preservative method. Salted fishes are left to dry on the beach for the duration of the fishing trip. Although this is an essential part of the salting process, it also serves the practical function of maximizing the vessel's daily haul capacity and may also reduce fuel consumption because of lower vessel weight on a daily basis. At this particular landing site, it was observed that women play a leading role in drying and smoking fishes for sale, more so than in other landing sites.

Fisherfolk reported that the main challenges they encounter are conflicts with other fisherfolk using drift seines because the Cadell lines become entangled in the seines. They also reported encounters with sharks as one of the main challenges they face. Drift seine fisherfolk indicated that sargassum (a specific type of seaweed) is the main challenge affecting them. The main expenses per trip are fuel and fishing bait for the Cadell lines. Each fishing trip costs approximately $11,000 GYD ($53 USD).

2 ONBOARD SUPERVISOR RESULTS

The onboard supervisor at this site who participated in the study uses Cadell lines (demersal longlines) to fish. His trips last for up to 10 days and he typically fishes approximately 9 kilometers from the shoreline offshore of the mouth of the Moruca River. On each fishing trip, approximately 5,000 Cadell hooks are soaked for approximately 1 hour. Lines are soaked 5 to 10 times per fishing trip depending on the number of days spent at sea. The vessel is fitted with an outboard cruiser with an engine size of 15 hp and a haul capacity of 500 kilograms (1,100 pounds). Each fishing trip has four crew members, inclusive of the onboard supervisor. The highest cost per fishing trip is fuel because of the relatively long 10-day trips.

During the reporting period, the onboard supervisor did not report any challenges that significantly affected his fishing practices. However, he indicated that the fuel shortage that seriously impacted fishing at Smith's Creek also had minor negative impacts on his fishing practice.

Due to challenges in scheduling meeting times with the onboard supervisor, the study team was only able to obtain data collected by the onboard supervisor for the May to November 2019 period.

2.1 Target Species and Diversity

During the study, the total weight of combined hauls from the onboard supervisor's vessel was 2,753 kilograms (6,069 pounds) from 1,128 hours of effort from May to October 2019. As seen on Figure G-1, sea catfish was the most abundant species caught by a significant margin accounting for 75 percent of the total haul with 2,083 kilograms (4,592 pounds). This is similar to the haul from the onboard supervisor from La Grange (Region 3) where fishing by Cadell lines had a haul in which sea catfish comprised 85 percent. Hauls from fishing activities using Cadell lines significantly targets species that are benthic feeders because the hooks attached to the lines lie on the seafloor and benthic fishes are more easily hooked. Cuirass and gillbacker were the second and third most abundant species caught with 551 kilograms (1,215 pounds) and 111 kilograms (245 pounds), respectively. Overall, only five species were caught by the onboard supervisor. No bycatch was recorded by the onboard supervisor using this fishing method.

This is lower than the species diversity reported by the onboard supervisor from La Grange (Region 3) and although sea catfish was the most abundant caught species by both supervisors, the species composition of the hauls also showed marked differences. For example, gillbacker was not caught by the onboard supervisor from La Grange while bangamary and smaller species like annafokes were not caught by the onboard supervisor from Waramuri. This may be attributed to a variety of factors including the smaller data pool for Waramuri and the supervisors' preferred fishing grounds. In addition, bycatch was not reported by the La Grange onboard supervisor.

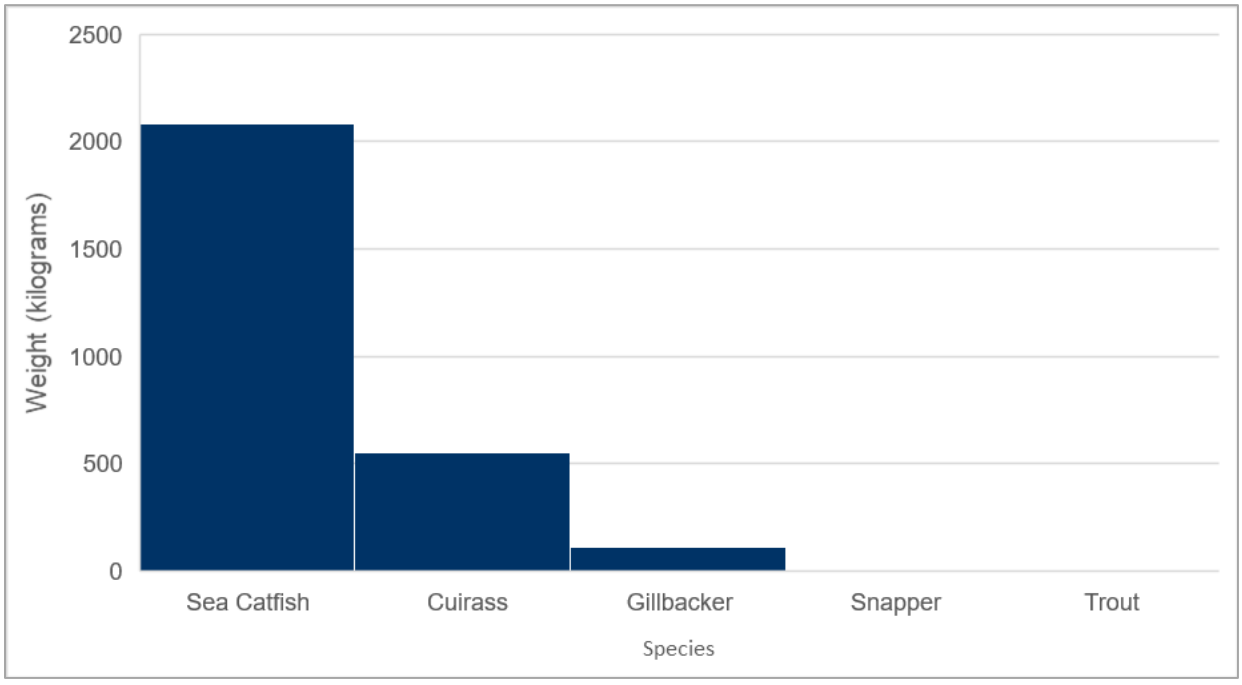

Figure G-1: Total Weight of Species Recorded by the Onboard Supervisor at the Waramuri/ Haimokabra Landing Site

2.2 Fishing Areas

As shown on Figure G-2, the main fishing area, where most of the fishing points are clustered, is within a zone of 65 square kilometers. The supervisor traveled 50 kilometers from the Waramuri landing site to access these fishing grounds. However, after leaving the landing site in Waramuri, the onboard supervisor landed at a beach area along the coast where the crew camped and where daily trips were launched. In total, the onboard supervisor has a traveling range of 458 square kilometers located along the coast of Region 1. Despite the distance traveled to access fishing grounds, the onboard supervisor stays relatively close to the shore compared to fishing activities of onboard supervisors from Regions 2 to 6. The farthest distance from shore at which a fishing point was located was 12.5 kilometers. This may be due to the lack of competition from nearshore fishing activities because fishing with Chinese seines and pin seines is not prevalent in Region 1.

Generally, several factors determine where the onboard supervisor decided to soak the fishing lines. These factors include the amount of fishes caught in these locations before, time and distance traveling to and from fishing grounds, and the presence of other fisherfolk or fishing activities in the area. All fish caught by the supervisor were mature.

Figure G-2: Fishing Area and Fishing Points Used by the Waramuri Onboard Supervisor

2.3 Seasonal Productivity

The onboard supervisor subscribes to the commonly-held view that fishing is most productive from May to September (the so-called “good season” that peaks in July to September) and less productive from October to March (the so-called “hard season”). It is widely believed that waters are warmer and calmer during the good season, and these conditions are more conducive to fishing. These seasons are believed to influence effort expended by fisherfolk as well as hauls per soaking of the seine and per fishing trip. Most of the data collected at Waramuri/Haimokabra was for the good season and therefore, unlike the analysis for other landing site fishing grounds cannot be analyzed for differences in fishing practices in the good versus the hard seasons.

The effort expended per fishing trip monthly, as seen on Figure G-3. Figure G-4 and G-5 show the total weight of hauls monthly and the average haul weight per soaking of the seine. In the May to September 2019 good season the total weight of hauls was 2,528 kilograms (5,573 pounds) with 984 hours spent at sea. On average, soaking of the seine in this period yielded 64 kilograms (141 pounds). During this period, the supervisor expended the greatest effort (384 hours spent fishing) and recorded the highest total haul with 774 kilograms (1,706 pounds). However, the average weight of hauls per soaking was 48 kilograms (106 pounds), which was the lowest during the good season. The greatest average hauls were observed in May and September 2019 with hauls of 79 kilograms (174 pounds) and 78.5 kilograms (173), respectively. In May, the total haul was 474 kilograms (1,045 pounds) from 144 hours of effort while in September, the total haul was 707 kilograms (1,558 pounds) from 216 hours of effort.

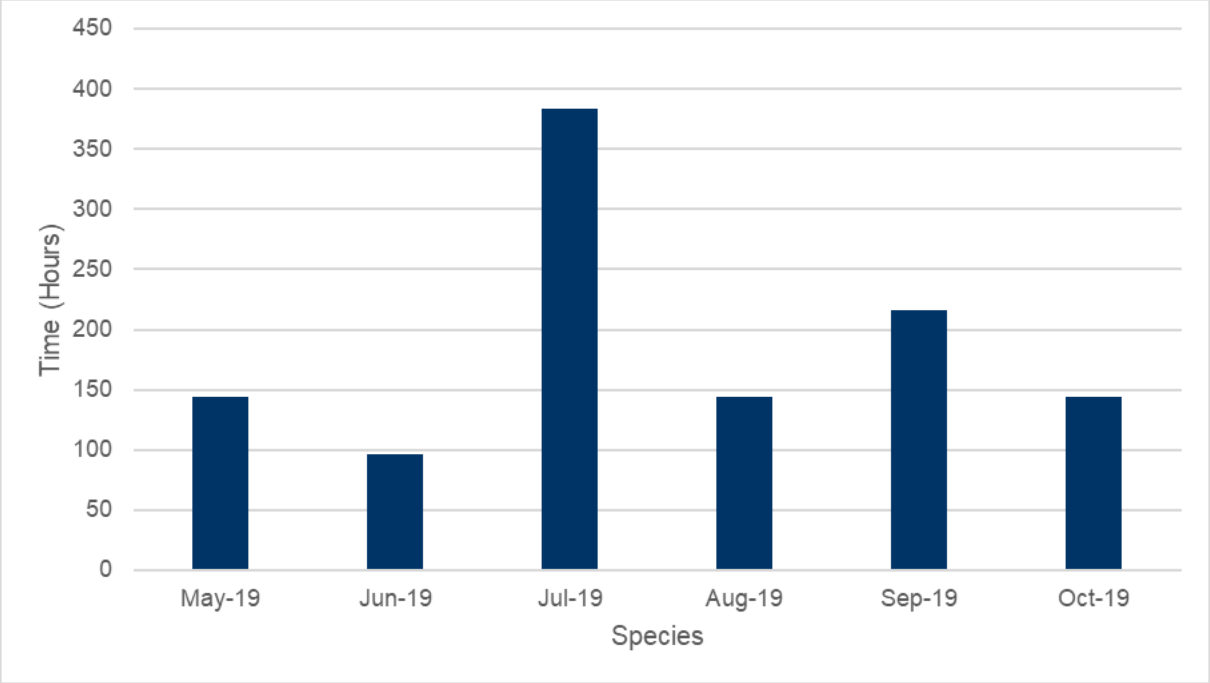

Figure G-3: Total Monthly Fishing Effort Recorded by the Waramuri/Haimokabra Onboard Supervisor

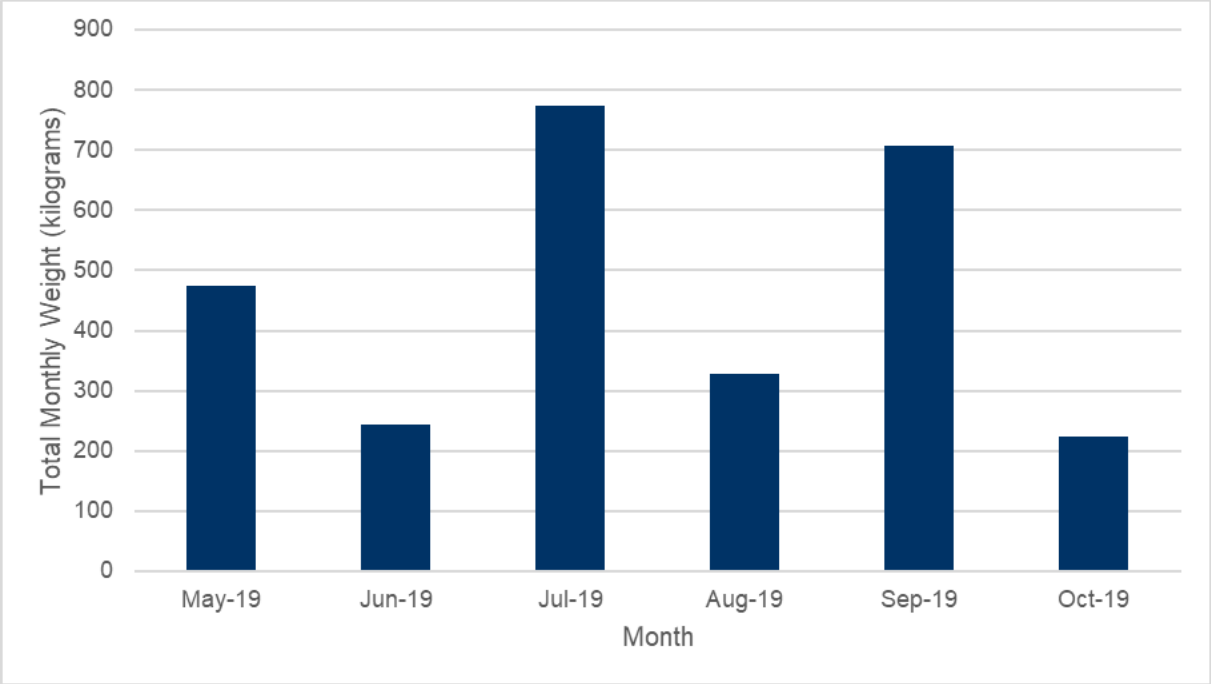

Figure G-4: Total Weight of Species Recorded by the Waramuri/Haimokabra Onboard Supervisor

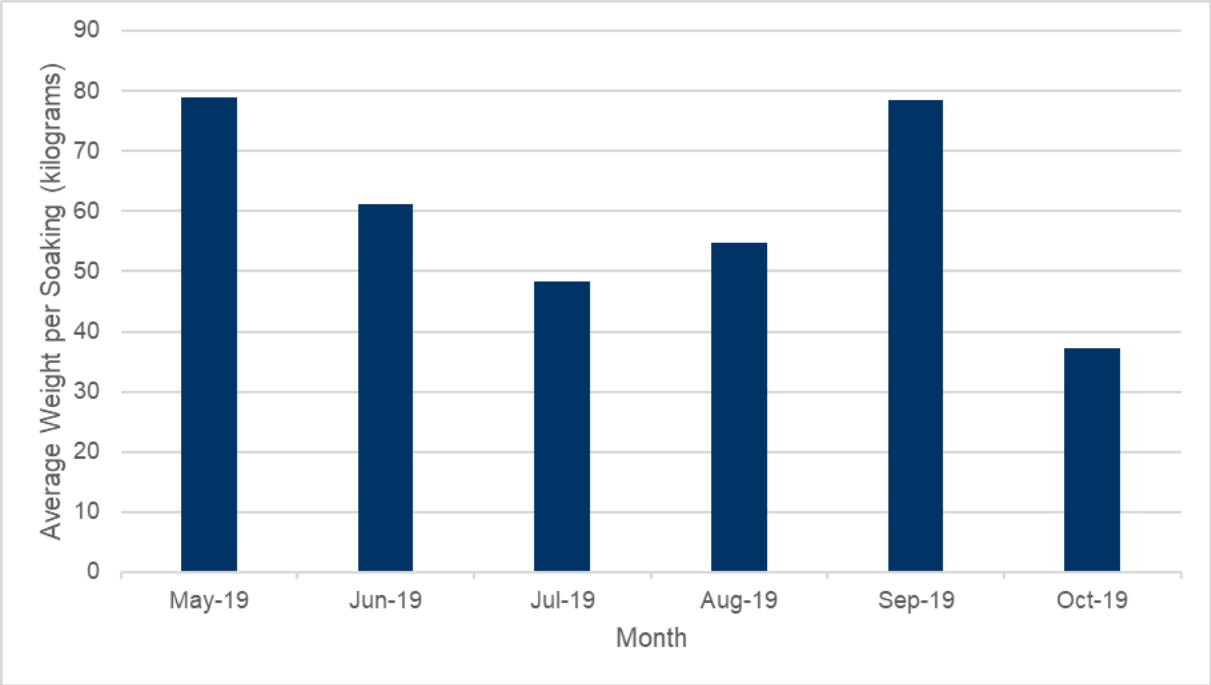

Figure G-5: Average Weight per Soaking Recorded by the Waramuri/ Haimokabra Onboard Supervisor

Based on the available data, productivity of the onboard supervisor's fishing activities could not be assessed for the entirety of the hard season from October 2019 to March 2020. However, October 2019 was one of the least productive months with a total haul of 224 kilograms (494 pounds). Although the total

haul in June 2019 was similar, there were significant differences in the total effort expended and average weight of hauls per soaking in these two months. In June 2019, the average weight of hauls per soaking was 61 kilograms (134 pounds) from a total effort of 96 hours, whereas in October 2019, the average weight of hauls per soaking was 37 kilograms (82 pounds) from a total effort of 144 hours. Similarly, the onboard supervisor expended comparable levels of effort, but total hauls were lower in October 2019 compared with 328 kilograms (723 pounds) in August 2019. This is directly a result of a higher average weight of total hauls per soaking of 55 kilograms (121 pounds) in August 2019, which is higher than the average weight of total hauls per soaking recorded in October 2019.

Seasonal trends in the primary wet and dry season were as follows:

- In August to October 2019, the primary dry season, total weight of hauls was 1,259 kilograms (2,776 pounds) with 504 hours spent at sea. On average, soaking of the seine in this period yielded 171 kilograms (377 pounds).
- In May to July 2019, the primary wet season, total weight of hauls was 1,439 kilograms (3,172 pounds) with 624 hours spent at sea. On average, soaking of the seine in this period yielded 63 kilograms (138 pounds).

There is not sufficient enough data to determine whether productivity of fishing supports fisherfolk views of the peak and off-peak fishing seasons. However, productivity was lowest in October 2019, which is typically when the hard season is believed to begin. Moreover, there was no definitive trend in productivity based on climatic seasonality because the difference in combined average productivity for the primary wet and dry seasons was not significant. Specifically, based on the data available, productivity was higher in the primary wet season than in the primary dry season. However, there was increased effort over the May to July primary wet season. The hauls from the onboard supervisor demonstrate that during the good season, increased effort is a reasonable predictor of increased productivity. In May and September 2019 there were comparable average weight of hauls per soaking but total hauls were greater in September when more effort was expended.

However, increased effort is not an indicator of increased productivity during the hard season. This is seen in June and October 2019, which had comparable total hauls, but greater effort was expended in October 2019 where the average weight of hauls per soaking is lower. Increased hauls per soaking in the good season may be attributed to several factors. In the wet season, greater nutrient loads are likely at the mouths of rivers, including the Moruca River, which may attract marine life. In the dry season, waters are warmer and calmer creating ideal conditions for fishes, which also act as an attractant. In addition, spawning season occurs during the July to September period, and fishes come closer to the shore to spawn.

2.4 Biometrics

The onboard supervisor measured the lengths and weights of representative fishes per each haul and the annual average lengths and weights of these fishes are shown on Figure G-6. Based on the measurements taken by the onboard supervisor, all of the fishes caught were sexually mature. By comparison, the onboard supervisor from the La Grange landing site captured adult and juvenile fish, but captures of juvenile bony fishes were largely confined to the hard season. He captured juvenile sharks throughout the year.

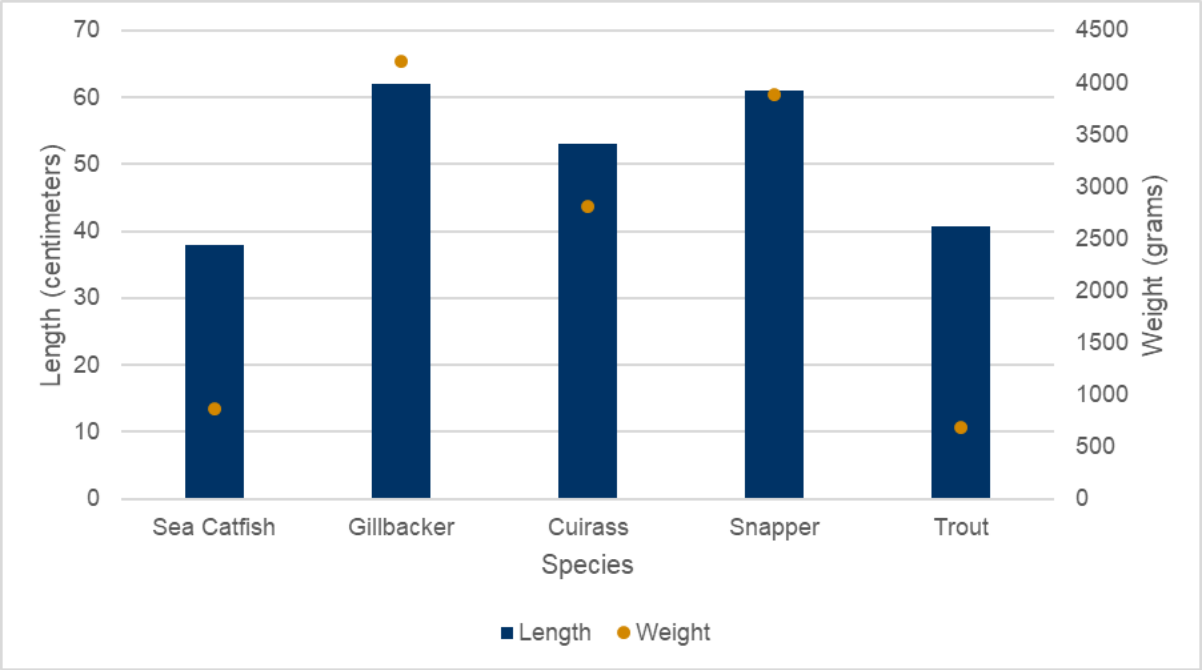

Figure G-6: Average Length and Weight of Fishes Caught by the Waramuri / Haimokabra Onboard Supervisor

The monthly average lengths and weights of the four most abundant species caught are presented on Figure G-7. All of the fishes measured had reached maturity. The largest, sea catfish, cuirass, and gillbacker, were caught in June and July 2019, after which sizes declined. This may have been due to more mature females with eggs coming closer to the shoreline to spawn in lagoons, estuaries, and mangroves. This trend is also seen in the data recorded at several other landing sites, like Smith's Creek, Charity, etc., where smaller fishes are caught after the spawning season ends.

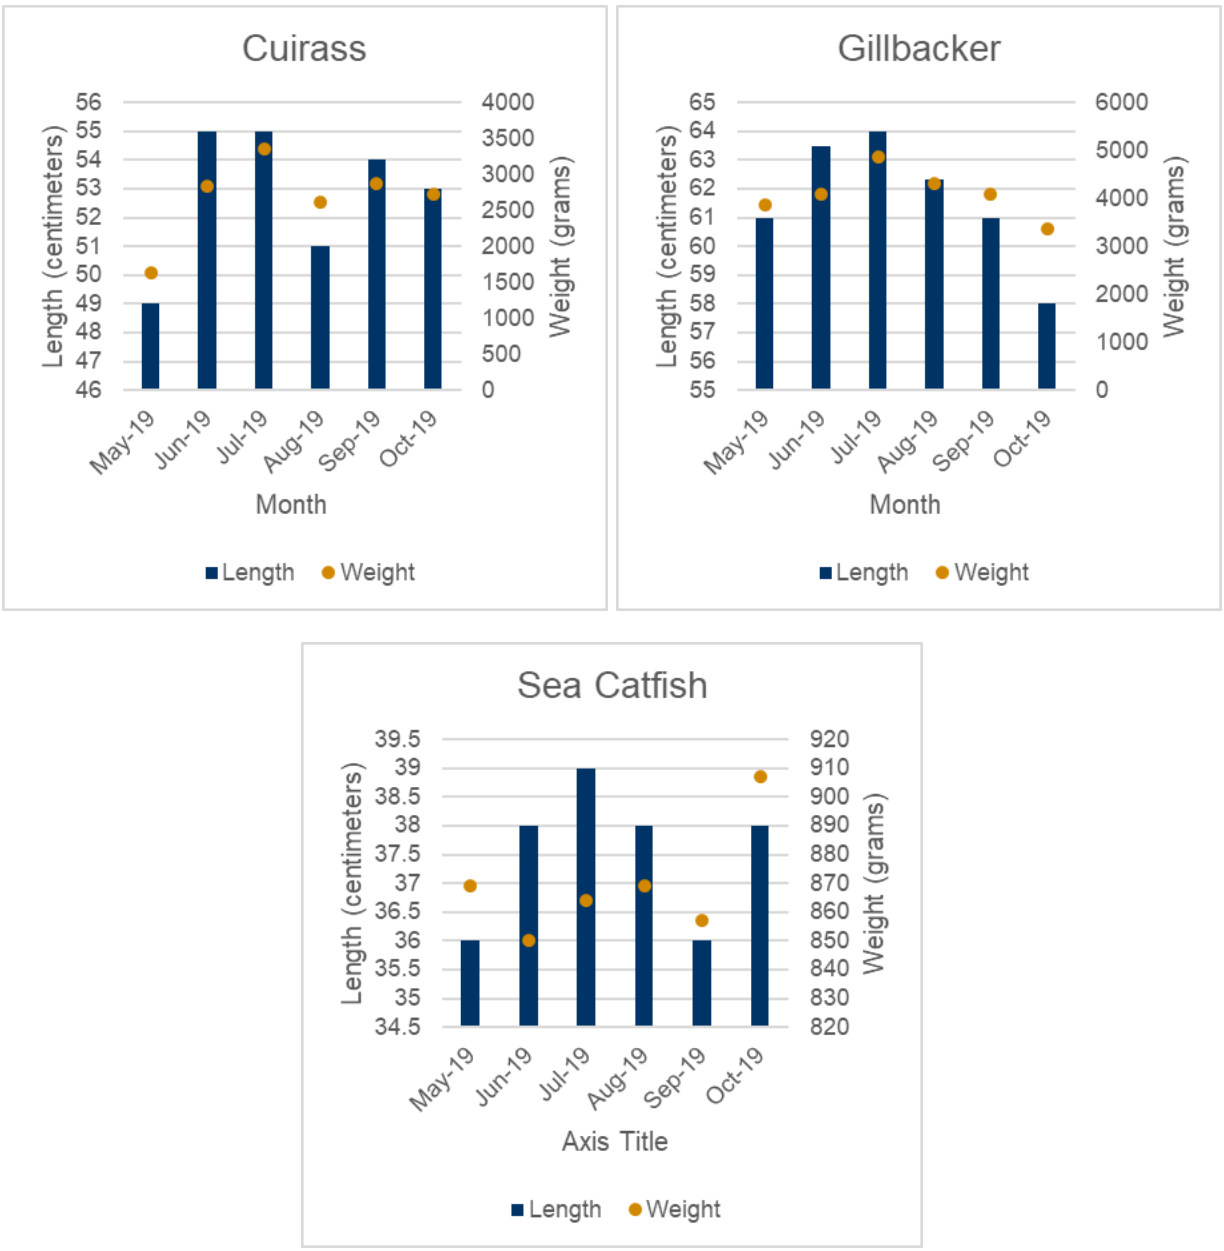

Figure G-7: Monthly Average Length and Weight of Most Caught Species by the Waramuri/Haimokabra Onboard Supervisor

3 QA/QC DATA

The study team initially intended to meet with the onboard supervisor's vessel when it landed to assess the haul, take biometric measurements, and compare these results to the data collected by the onboard supervisor. However, this could not be accomplished due to unexpected schedule changes in the supervisor's expected return date to shore. As an alternative, the team visited the Kumaka Market in Santa Rosa in an effort to meet another fisherfolk who used the Cadell method of fishing and who preferred the same fishing ground as the onboard supervisor. However, none of the fisherfolk at the market at the time used the Cadell fishing method. All of the fisherfolk used drift seines with variable mesh sizes. As a result of these challenges, the team could not conduct QA/QC exercises of the onboard

supervisor's haul and also was unable to assess hauls from a similar fishing type. Due to COVID-19 restrictions, a subsequent visit to conduct the QA/QC exercise did not occur.

APPENDIX H CHARITY (REGION 2)

1 LANDING SITE OVERVIEW

Charity is one of the main ports in Region 2 with commercial passenger vessels, produce vessels, and artisanal fishing vessels all using it as an embarkation/disembarkation site. It is the largest landing site by volume of landed fish in Region 2. Fishing by vessels at this landing site occurs along the Essequibo Coast (Region 2), and northwest from Charity to the Waini River (Region 1). Both inboard and outboard cruisers (designation for where the engines are placed on the vessel) operate from this port. Inboard cruisers, the type of boat most frequently landed at the site, have engines of 100 hp or more (Figure H-1), and are the largest artisanal fishing vessels in Guyana. Unlike many other vessels in Guyana, inboard cruisers would have engines that are built inside the boat. Outboards have an engine on the outside of the vessel that is easily removed.

The landing site is located in the waterfront area of the privately-owned Big Bird and Sons Fish Port Complex that includes an ice factory from which fisherfolk purchase ice to be used for fish preservation during fishing trips. Fisherfolk from as far as Mabaruma in Region 1 visit the Complex to purchase ice when there are shortages in their area. The Complex also provides a ready marketplace for landed vessels at Charity as vendors visit the site to purchase hauls from fisherfolk. In addition, large quantities of fishes are also purchased by the proprietors of the Complex for export. Fisherfolk indicate that an artisanal fleet of up to 70 vessels use the site.

Figure H-1: Inboard Cruiser at the Charity Landing Site

Vessels use drift seines with mesh sizes of 10 to 20 centimeters (4 to 8 inches) to target snapper. These vessels have extended fishing trips averaging 15 days at sea. Hauls also include jewfish (endangered, rare, and protected species) and shark species, some of which may be considered endangered, rare, protected, or vulnerable species. Due to the extended number of days spent at sea, fishes are usually de-gutted before vessels land at Charity. (Note: This practice hindered biometric measurements at this landing site.) Fisherfolk spend $40,000 to 540,000 GYD ($191 to 2,583 USD) to conduct a fishing trip and have haul sizes of 200 to 1,700 kilograms (440 to 3,740 pounds) of fishes. Their main expenses are ice (some indicated ice shortages) and fuel.

Fisherfolk from this landing site reported conflicts with other fisherfolk associated with sharing preferred fishing grounds, conflicts with trawlers that are believed to cut the lines of the drift seines, and conflicts with Venezuelan vessels fishing in Guyana's waters. Fisherfolk also shared fears of theft and threats to personal safety that would arise from acts of piracy, but incidences of piracy were reported during the study period. Some fisherfolk also reported that seaweed in the mouth of the Pomeroon River that flows up to the Waini River also affects their fishing activities (during the January to March 2019 season). Some fisherfolk are also challenged by significant variability in prices for fishes at the landing site at different times of the year.

2 REGIONAL SUPERVISOR RESULTS

One regional supervisor participated in the study. Most vessels at this site are inboard cruisers that use drift seines with mesh sizes from 10 to 20 centimeters (4 to 8 inches) to target snapper. Although there is a small population of "bangamary boats" that target bangamary and use drift seines with mesh sizes of 7 centimeters (2.75 inches), the study team advised the regional supervisor to focus data collection efforts on inboard cruisers because they were unique to this landing site. These vessels were mainly the inboard cruisers. As such, only two data sets from the vessels that target bangamary were collected, and as a result, the data reported herein on bangamary should not be considered as representative of hauls from all vessels.

2.1 Effort and Haul

Based on the data collected, 14 commercial species were caught with a combined weight of 105,470 kilograms (232,521 pounds). This overall catch volume is significantly higher than the data recorded for other landing sites and is principally attributed to the use of inboard cruisers that have significant haul capacities and typically conduct extended fishing trips. As a preservative measure during prolonged fishing trips, fishes are gutted at sea, whereas at other landing sites with regional supervisors, the recorded landed weights are of fishes that are whole/un-gutted. Total haul volumes per trip for vessels at the Charity landing site are higher compared to data collected by the other regional supervisors due to the prolonged time the vessels spend at sea when compared to the other types of vessels.

Inboard cruisers typically fish along the Essequibo Coast (Region 2), but are known to frequently travel to fishing grounds ranging from the mouth of the Pomeroon River to the mouth of the Waini River (Region 1). These vessels fish from 3 to 48 kilometers from the coastline and in depths of approximately 70 meters. Compared to other vessels in Guyana's artisanal fleet, inboard cruisers typically spend upward of 2 weeks at sea per fishing trip because of larger capacities that accommodate crew, maintain a stock of supplies, and store hauls on ice. Moreover, gutting fishes at sea is not only a preservation method but also reduces the total weight of fishes stored onboard. This facilitates increased soakings of the seine per fishing trip and creates the opportunity for maximizing the vessel's haul capacity on each fishing trip.

Over the April 2019 to February 2020 period, a fishing trip lasted for 15 days on average. However, the average duration of fishing trips varied on a monthly basis (Figure H-2) and no clearly discernable trend for consecutive months was observed. For example:

- The shortest average monthly trips lasted for approximately 14 days and were observed in May, July, and September of 2019 and also in January 2020. The shortest trip recorded in these months was 10 days and the longest was 18 days.
- The longest average monthly trips lasted for approximately 16 days and were observed in April, June, August, and November of 2019, and again in February 2020. The shortest trip recorded in these months was 8 days and the longest was 19 days.

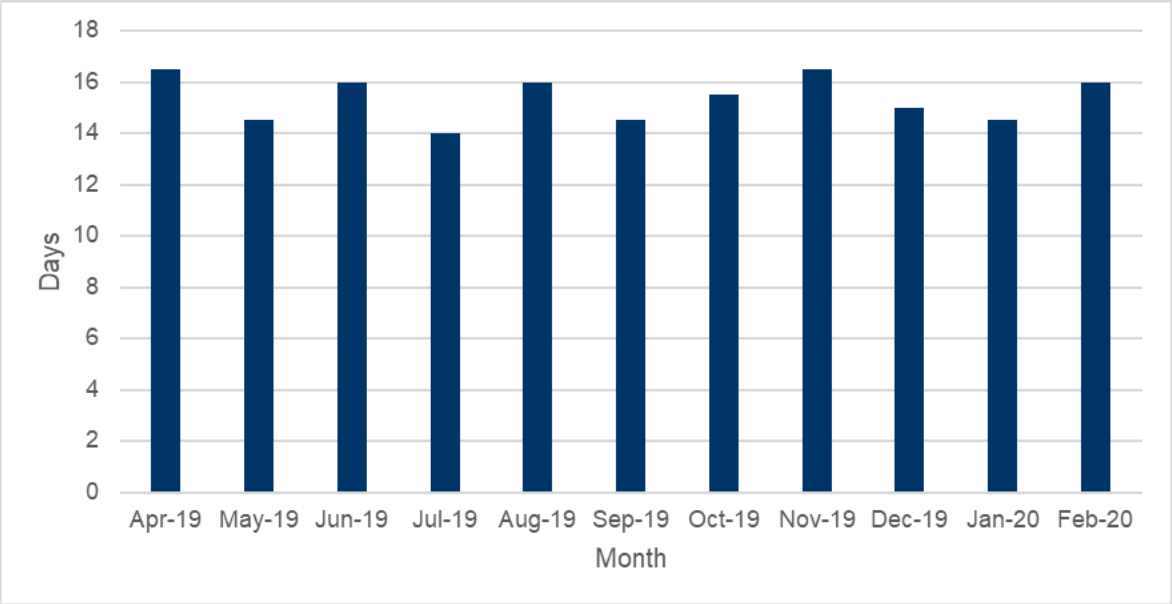

Figure H-2: Average Monthly Fishing Effort at the Charity Landing Site

2.2 Target Species and Diversity

Snapper is the fish most caught by weight at this landing site (see Figure H-3) with a total weight of 63,537 kilograms (140,075 pounds); snapper accounted for 60 percent of total haul weight. This was expected as most of the data were collected from vessels that target snapper. Trout was the second most abundant species caught with a total weight of 14,733 kilograms (32,480 pounds); cuirass was the third with 11,005 kilograms (24,261 pounds), and cuffum fourth with 5,592 kilograms (12,328 pounds). These four species as well as the 10 other species that were caught all tend to be comparatively large-bodied fish. Catch comprising large fishes is typical of snapper seines, which have the largest mesh sizes used by artisanal fisherfolk, which limits capture of smaller species and smaller fishes. This was also observed at other landing sites where seines with larger mesh sizes are used including Hampton Court (Region 2), Bushlot and Rosignol (Region 5), and Complex 66 (Region 6).

In addition, endangered, rare, and protected species were also reported in hauls from this landing site. Jewfish was also reported at the Charity landing site from fishing trips to the Waini River in June 2019 and February 2020. It is likely that these vessels shared common fishing grounds with the fisherfolk from Smith's Creek and Morahwanna who caught jewfish in the Waini River in May, September, October, and December 2019, and January 2020. Shark were caught in greater quantities than jewfish, but were not reported by species so it was impossible to determine whether they included endangered, rare, or protected species.

Of 14 different species of fishes caught by fisherfolk at this landing site, no more than 9 were caught in any given month (see Figure H-4). Seasonal trends were not evident in species diversity and most of the fishes caught are not migratory. Species diversity is significantly lower than that observed at Smith's Creek and is principally due to the use of seines with large mesh sizes that allow most of the smaller fisher and smaller species of fish to escape.

Most of the fishes measured at this landing site had achieved sexual maturity.

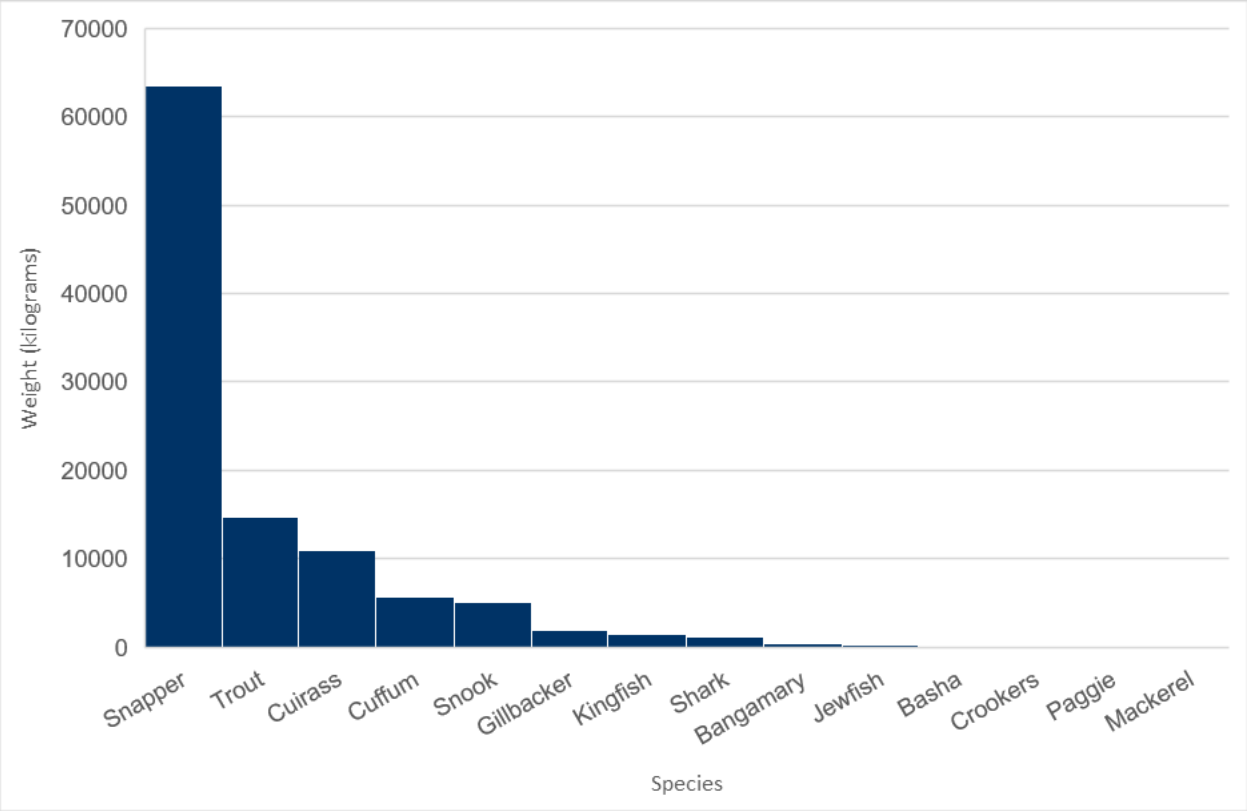

Figure H-3: Total Weight of Species Caught at the Charity Landing Site

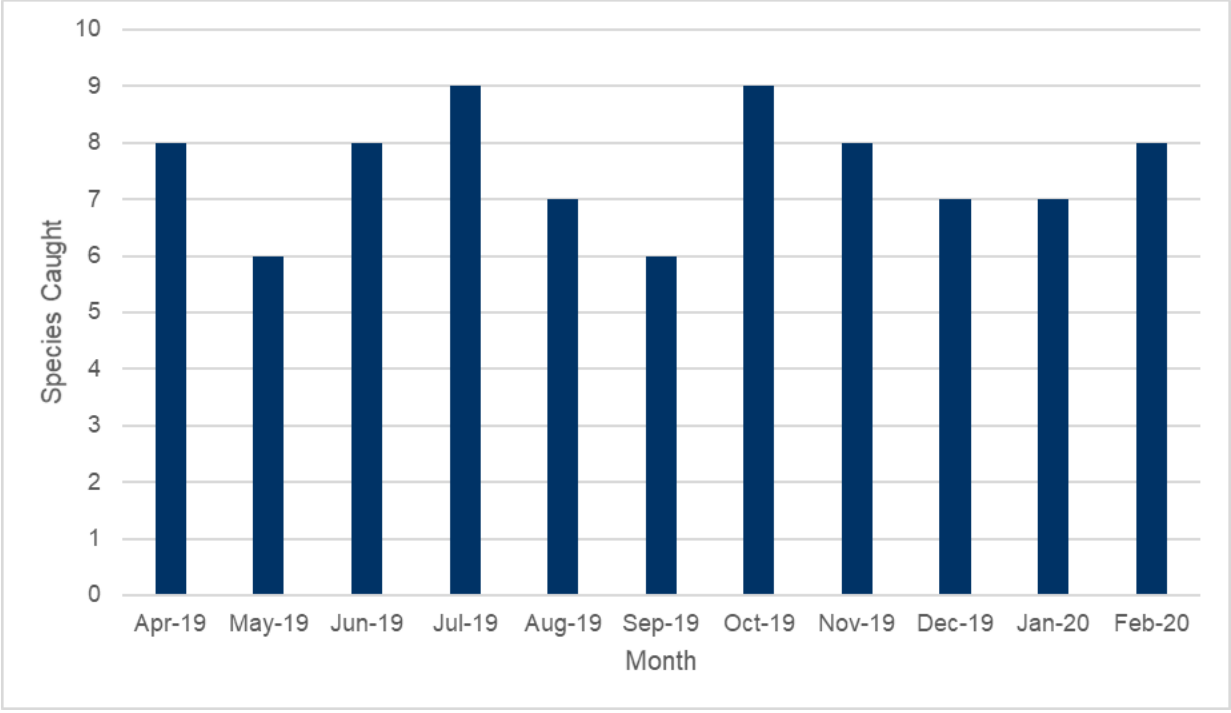

Figure H-4: Species Diversity at the Charity Landing Site

2.3 Seasonal Productivity

Artisanal fisherfolk in Guyana subscribe to the commonly-held view that fishing is most productive from May to September (the so-called “good season” that peaks in July to September) and less productive from October to March (the so-called “hard season”). It is widely believed that waters are warmer and calmer during the good season, and these conditions are more conducive to fishing. These seasons are believed to influence effort expended by fisherfolk as well as hauls per soaking of the seine and per fishing trip. Figure H-5 presents the average monthly productivity of hauls, which was measured as total monthly productivity (in kilograms) divided by the number of fishing trips. As expected, the average monthly productivity varied with the following key observations:

- The highest average monthly productivity with hauls greater than 1,000 kilograms (2,205 pounds) were observed in May, July, and September 2019. May was the most productive month with an average productivity of 1,091 kilograms (2,405 pounds). These were the same 3 months in 2019 when the least effort was expended per fishing trip. However, it is not evident whether less effort was expended by design, or whether a greater abundance of fishes allowed fisherfolk to achieve optimum haul capacities more quickly. The months of June and August 2019 recorded the second greatest average monthly productivity with hauls greater than 900 kilograms (1,984 pounds). However, greater effort was expended per fishing trip during these months.

- By contrast, average monthly capacity was 800 kilograms (1,764 pounds) or lower in April 2019, and over the October 2019 to February 2020 period. February 2020 was the least productive month with an average productivity of 624 kilograms (1,375 pounds) and was also one of the months during which most effort was expended. This may be attributed to a spring tide cycle that made the seas extremely rough, challenging the mobility of fisherfolk and increasing the difficulty of fishing activities.

By comparison, combined capacities for wet and dry seasons were as follows:

- From May to July 2019, the primary wet season, the average combined haul was 356 kilograms (785 pounds).

- From August to October 2019, the primary dry season, the average combined haul was 368 kilograms (811 pounds).

- From November 2019 to January 2020, the secondary wet season, the average combined haul was 368 kilograms (811 pounds).

- From February 2020 to April 2020, the secondary dry season, the average combined haul was 390 kilograms (860 pounds). Data were not able to be collected for March 2020 to complete the trend for this season.

The trends observed in average monthly productivity support fisherfolk views of the peak and off-peak fishing seasons. Guyana’s wet and dry seasons do not appear to influence productivity as combined average productivity for the primary wet and primary dry seasons was not significant. In fact, the peak season comprises consecutive months of the primary wet and dry seasons. These are also different from the seasonal trends observed at Smith’s Creek where average monthly productivity was lower in the May to July wet season as compared to the August to October dry season. However, as previously noted, fuel prices peaked in Smith’s Creek during the May to July period, which curtailed fishing activities at that landing site.

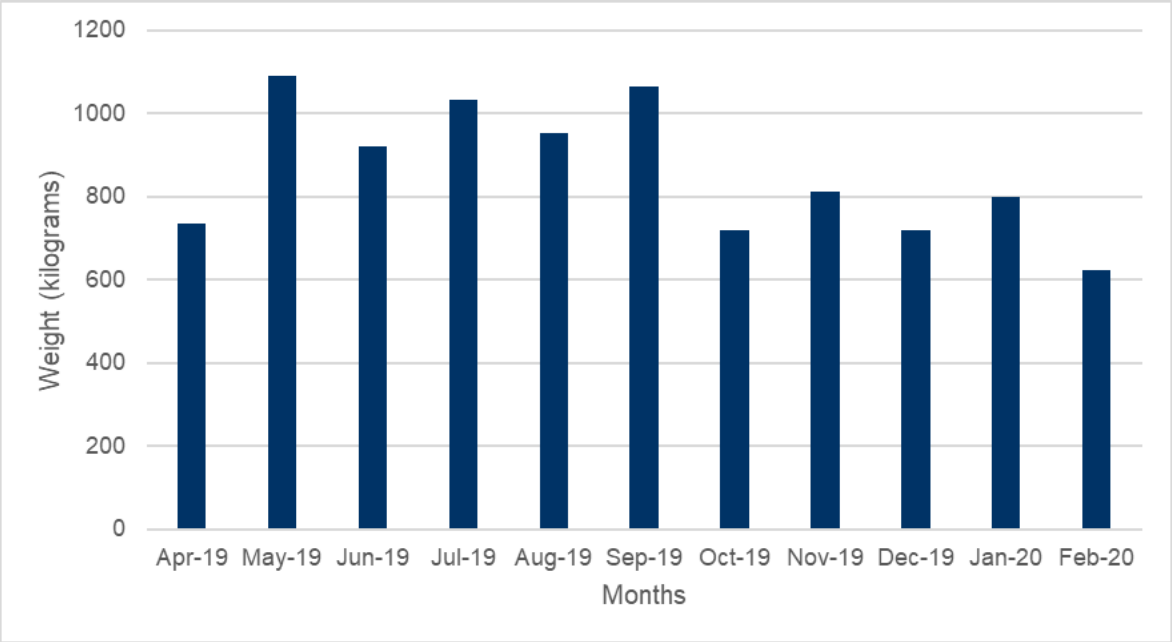

Figure H-5: Average Monthly Productivity of Fishing Trips at the Charity Landing Site

2.4 Prices and Markets

In total, sales of fishes at this landing site were the highest earnings at any landing site at which regional supervisors collected data. Snapper is the most expensive fish by kilogram (Figure H-6) with an annual average price of $719 GYD ($3.5 USD) per kilogram. Gillbacker was the second most high-value species with an annual average price of $610 GYD ($2.9 USD). Previously, the gillbacker was sold for the highest prices at this landing site and other areas of the country due to high demand on the export markets. However, prices dipped following the cessation of exports to the United States in 2018. Trout and bangamary were the third and fourth most high-value species, with average prices of $339 GYD ($1.6 USD) and $231 GYD ($1.1 USD), respectively. Jewfish and shark were not high-value with comparable annual average prices of $132 GYD ($0.6 USD) and $129 GYD ($0.6 USD), respectively. Based on the data collected by the regional supervisor, earnings from sales at this landing site totaled $54,725,111 GYD ($263,101 USD).

Earnings per fishing trip are also increased by sale of the glue (swim bladders) of snapper and to a lesser extent, of trout. Prices at which glue was sold throughout the year were not collected by the regional supervisor as part of the study. However, interviews with the regional supervisor and fisherfolk at the landing site indicated that the price per kilogram of glue from snapper and trout is consistently greater than the price per kilogram of the flesh of these fishes. Moreover, eggs harvested from sexually mature fishes are also sold separately from the flesh and reportedly the highest demand for eggs is from gillbacker. Generally, fisherfolk using inboard cruisers heavily depend on the sale of these products, particularly glue, to make fishing trips economically feasible as a single fishing trip using these vessels costs approximately $540,000 GYD ($2,583 USD). The maximum approximate income per trip was recorded during August 2019, which was $648,740 GYD ($3,119 USD), and the minimum approximate income per trip was recorded in October 2019, which was $304,489 GYD ($1,464 USD).

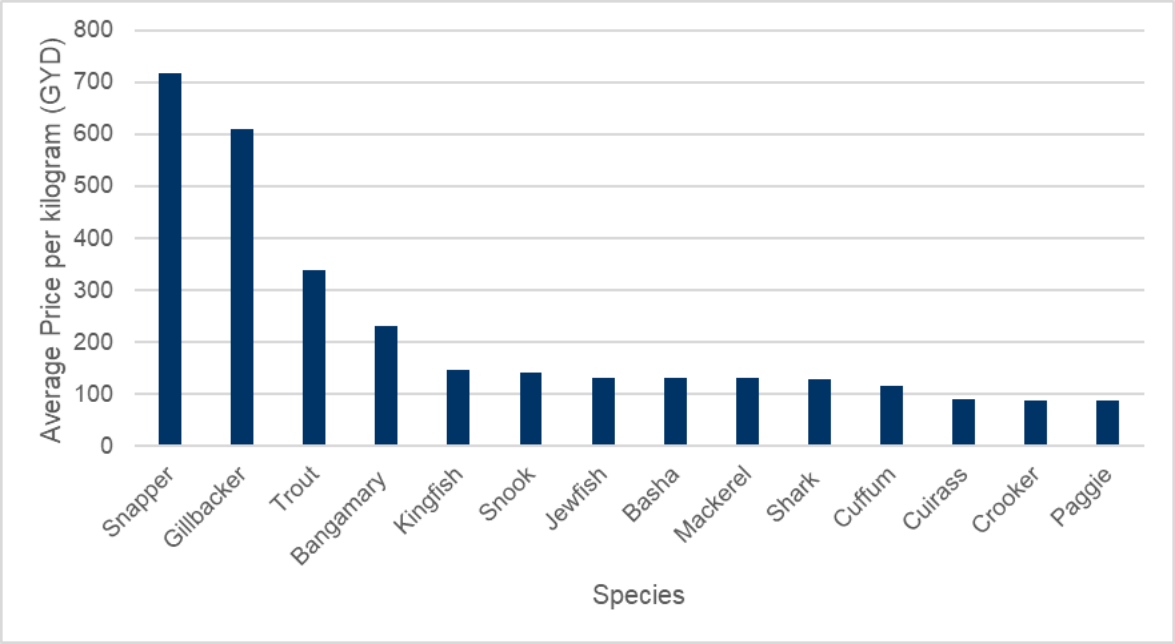

Figure H-6: Annual Average Price per Kilogram of Fishes at the Charity Landing Site

In general, the prices at which fishes are sold varies by species and season and Figure H-7 shows the minimum, maximum, and average prices for the four most abundant species caught. Prices of the target species, snapper and trout, and other high-value species like gillbacker are relatively consistent. The differences between minimum and maximum prices for these species are also negligible during most periods of the year. Nonetheless, prices are likely to swing in response to market forces. For example, the prices of snapper significantly increased in July and August 2019 and the regional supervisor indicated that during this period, demand for export of snapper to China increased. Prices subsequently declined in September and October 2019 due to lower demand for exports to China, which was reportedly related to the protests in Hong Kong and the resultant surplus of fish in the local marketplace. The regional supervisor also indicated that the demand for snapper glue also sharply declined around this time.

Fisherfolk indicated that the price decline challenged the economic viability of their fishing activities and some opted to store the glue harvested from the fishes for sale until market prices again increased. By November 2019, prices had returned to those observed in the April to June 2019 period, but started to climb once more from December 2019 to February 2020, presumably due to lower supply as the hard season progressed. Trout, from which glue is also harvested for sale and export, also experienced price declines for the flesh of the fish that were similarly related to the loss of glue markets. Unlike snapper, the prices were lowest during the hard season.

The annual average prices of trout, cuirass, and cuffum were significantly lower than for snapper. Cuirass was one of the lowest-priced species and prices were stable throughout the year except for spikes in June, August, and September 2019. Prices also remained stable throughout the hard season. The reason for these price spikes is unknown. The prices of cuffum varied significantly throughout the year and major differences in minimum and maximum prices were also observed. Like trout, the lowest prices were observed in the hard season. This trend suggests that prices of middle-value and lower-value fishes may not be as responsive to market forces and scarcity as are high-value species like snapper.

Figure H-7: Monthly Price Variations of the Four Most Abundant Species Caught

2.5 Biometrics

The regional supervisor measured the lengths and weights of fishes that were representative of hauls for which data were collected. The annual average length and weight of these fishes are presented on Figure H-8.[2] However, it should be noted that the practice of gutting fishes at sea has reduced the total weight of landed fish at this site compared to other landing sites in the study. Jewfish was the largest species caught with a length of 152 centimeters and gutted weight of 149,685 grams (330 pounds). Only two jewfish catches were recorded during the reporting period. The fishes caught at the Charity landing site would be considered sexually mature, unlike those captured at the Smith's Creek/Morahwanna landing site. Based on the reported lengths, it is unlikely that any of the sharks landed had reached sexual

[2] Jewfish is not included on Figure H-8 because, with an annual average weight of 149,685 grams (330 pounds) and an average length of 152 centimeters, it significantly skews size representations for the other species.

maturity. Overall, the annual average lengths and weights of the other species caught indicate that they have reached sexual maturity. The trend of larger fishes of the species caught with seines that have large mesh sizes is expected and has been observed at other landing sites.

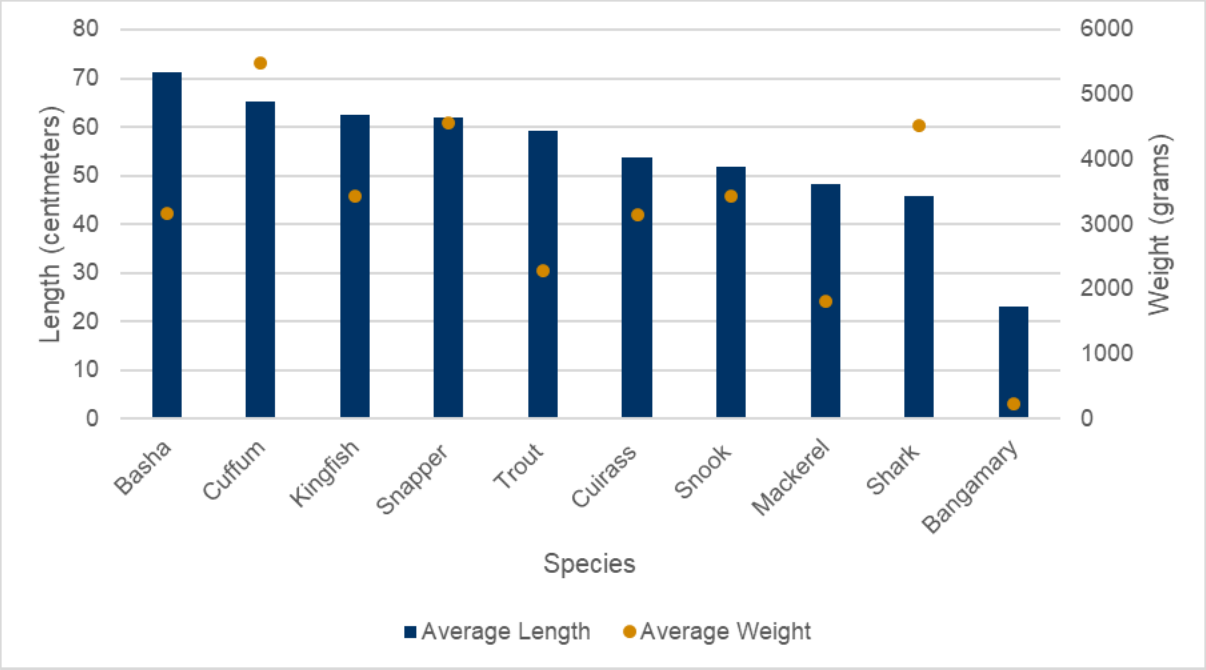

Figure H-8: Annual Average Lengths and Weights for Fishes Measured at the Charity Landing Site

The monthly average lengths and weights of the four most abundant species caught (Figure H-9) show some variability, but most of the species were considered sexually mature. The smallest—snapper, trout, and cuirass—were recorded in February 2020, which was also the month with the lowest annual average productivity and one of the months of greatest effort. The largest fishes of these four species were caught in the April to September peak season and smaller fishes were caught in October and November 2019. Larger snapper, cuirass, and cuffum were once again caught during the December 2019 to February 2020 period for.

This is similar to the trend that was observed at Smith's Creek and Morahwanna. As previously discussed, size variation may be attributed to two reasons. Lowe-McConnell (1962) suggested that fishes come closer to shore during the rainy seasons due to increased nutrient flows and calmer trade winds. Fishes subsequently return close to the shore in August to September for spawning.

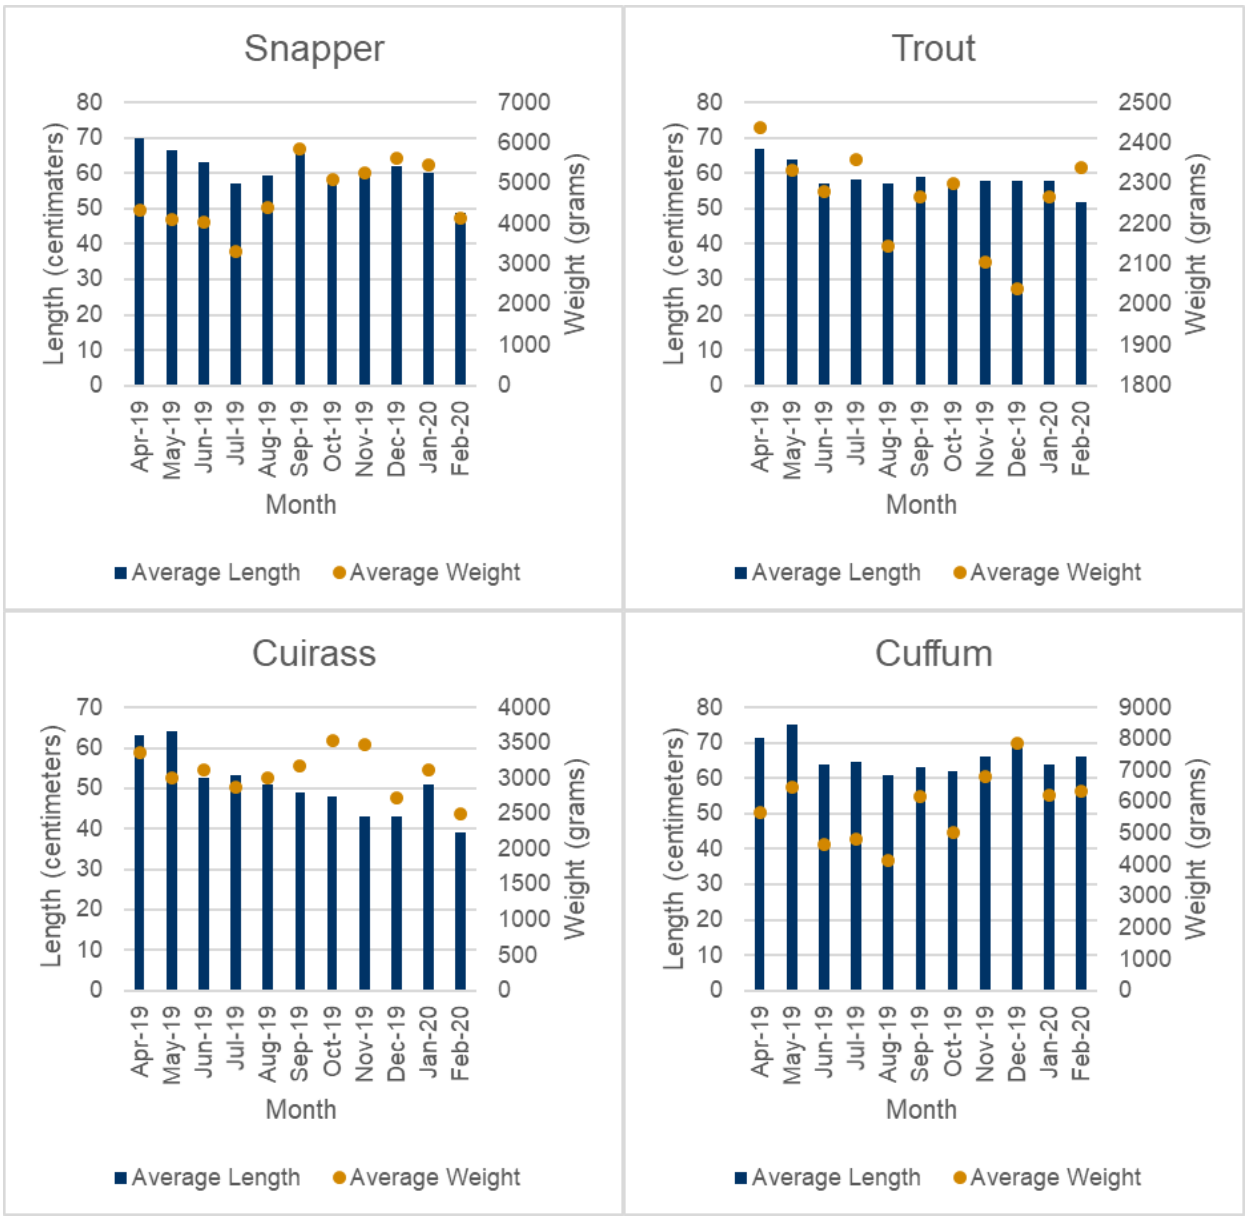

Figure H-9: Monthly Average Lengths and Weights of Most Abundant Species Caught

3 QA/QC DATA

During the initial visit, the regional supervisor at the Charity landing site collected data from inboard cruisers that target snapper and use drift seines with mesh sizes of 18 centimeters (7 inches). Over the 3-day period for which the QA/QC exercise was conducted in Region 2, no inboard cruisers landed at the site. The regional supervisor indicated that this is common as inboard cruisers do not frequently land. Due to these circumstances, the QA/QC assessment of data collected by the regional supervisor could not be conducted.

During the second QA/QC exercise, an inboard cruiser landed at this site, but this vessel did not have a successful fishing trip, deemed locally as a “bust trip.” The vessel was forced to return to the landing due

to mechanical difficulties after having only spent 5 days fishing. The total haul of the vessel was 376 kilograms (829 pounds). As seen on Figure H-10, snapper was the most abundant species caught, and with a total weight of 220 kilograms (485 pounds), it accounted for 59 percent of the total haul. Trout was the second most abundant species caught at 99 kilograms (218 pounds). These are normally the two most commonly landed species at the landing site based on the data collected by the regional supervisor. Prices of snapper from this trip were $748 GYD ($3.6 USD) per kilogram, trout $308 GYD ($1.4 USD) per kilogram, mackerel $143 GYD ($0.7 USD) per kilogram, and snook $132 GYD ($0.6 USD) per kilogram. These were all consistent with the level of pricing recorded by the regional supervisor throughout this period.

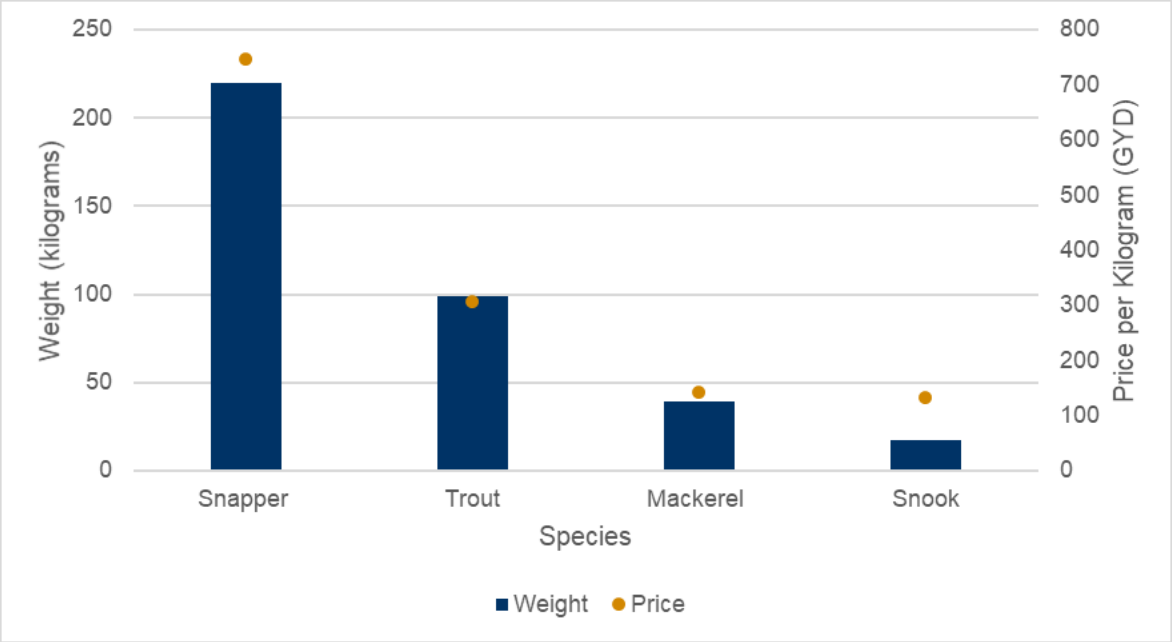

Figure H-10: Total Weight and Prices of Fishes from Vessel Assessed during the Second QA/QC Exercise

Biometric data collected from the catch was similar to those recorded by the supervisor. However, there was significant variance in the sizes of the snapper with the measurement during the QA/QC exercise being approximately 20 centimeters greater than the annual average lengths of fishes measured by the regional supervisor (Figure H-11). Random selection of fishes and the larger data pool on which the average lengths were calculated for the regional supervisor's measurement may account for the change. Overall, the study team was satisfied with the data collected; however, due to the relatively small sample size from the vessel from which the data were collected, more analysis would be needed to completely satisfy QA/QC requirement. However, the general trends seen in the data would represent accurate trends that were seen from the data collected by the regional supervisor hence the data can be deemed credible.

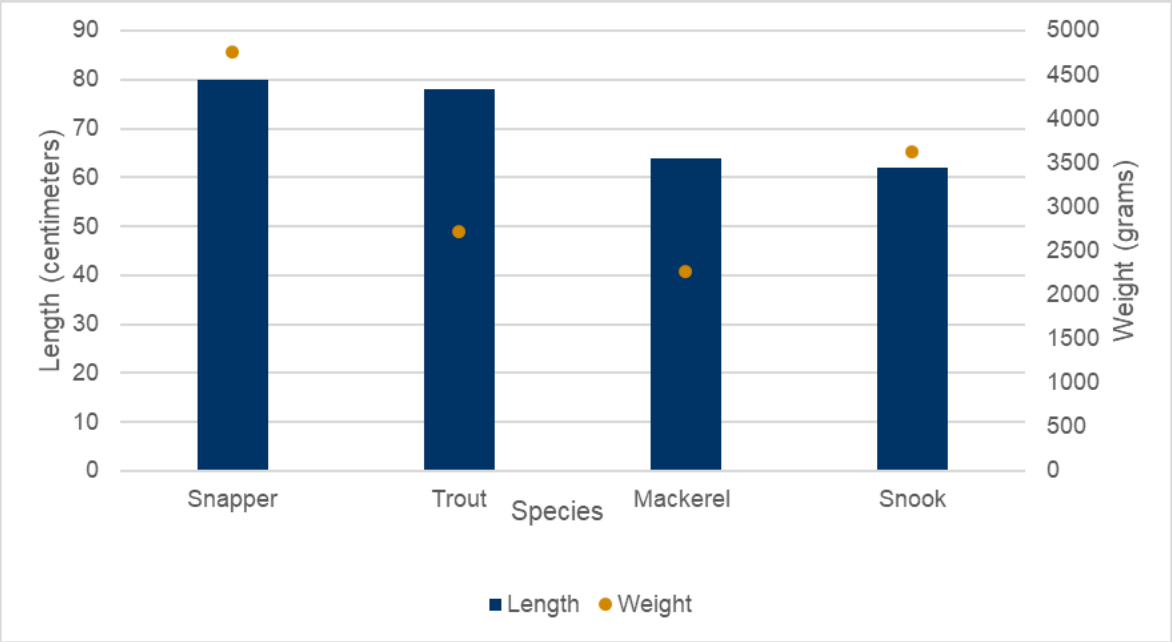

Figure H-11: Lengths and Weights of Fishes Measured during the Second QA/QC Exercise

APPENDIX I HAMPTON COURT (REGION 2)

1 LANDING SITE OVERVIEW

The Hampton Court landing site is one of the largest landing sites on the Essequibo Coast (Region 2) and is used by vessels that target both fishes and shrimp. Approximately 22 vessels use the Hampton Court landing site, all of which are outboard cruisers with engine sizes ranging from 5 to 60 hp. Larger vessels, with engines of 40 hp or greater, travel farther from the coastline and spend 2 to 6 days and typically use drift seines with mesh sizes of 13 to 20 centimeters (5 to 8 inches) to target larger fishes like snapper, gillbacker, and trout. Smaller vessels, with engine sizes of less than 40 hp, make fishing trips lasting for 1 day or less and use Chinese seines with mesh sizes of 2.5 to 10 centimeters (1 to 4 inches) to target shrimp and smaller species of fish. Seines are typically soaked for 4 to 6 hours. In general, fisherfolk at this site usually fish 3 to 16 kilometers from the coastline and fish up to 15 meters deep.

The main commercial species caught by fisherfolk are cuirass, snapper, bangamary, shrimp, gillbacker, and trout. During the peak season, hauls from vessels using drift seines range from 455 to 682 kilograms (1,000 to 1,500 pounds) of fishes while hauls from vessels using Chinese seines were approximately 38 kilograms (85 pounds) of shrimp. Most of the fishes caught are sold to vendors who export fishes and visit the landing site with refrigerated trucks. However, some fisherfolk sell produce in nearby villages or to vendors for sale in local markets. Prices per kilogram of fishes vary by species. For example, the price per kilogram of shrimp was $220 GYD ($1.05 USD) while high-value fishes such as snapper and gillbacker were sold for more than $600 GYD ($2.90 USD) per kilogram. Costs per fishing trips for the vessels using Chinese seines were approximately $1,000 GYD ($4.80 USD) while $100,000 GYD ($478 USD) is required for the larger vessels.

The principal challenges encountered are trawlers, sargassum, piracy, jellyfishes, ice shortages, and theft. There are frequent conflicts between the fisherfolk at the Hampton Court landing site who use drift seines and Chinese seines. Conflicts were also reported with fisherfolk who use Cadell lines and fisherfolk who practice anchor seine fishing along the Region 2 coastline. According to the Department of Fisheries, vessels using anchor seines are only allowed to fish in Region 3.

2 ONBOARD SUPERVISOR RESULTS

The onboard supervisor who participated in the study at this landing site uses a drift seine with mesh sizes of 20 centimeters (8 inches) to target larger species of fishes, specifically the high-value species gillbacker and snapper. The vessel used has a haul capacity of 907 kilograms (2,000 pounds) and is powered by two 48 hp engines. Most of the hauls from the onboard supervisors are sold to fishing trucks that visit this landing site to purchase fishes for export. The onboard supervisor's fishing trips typically last 2 to 8 days. Each fishing trip requires a three-member crew. The main expenses per fishing trip are for crew rations, fuel, and ice for the preservation of the haul. Due to the prolonged periods spent at sea, the supervisor also guts fishes before icing them during the fishing trip. When gutting fish, the supervisor harvests the swim bladders (glue) from the snapper and trout. These are iced and sold separately from the flesh of the fishes upon return to the landing site.

During the April 2019 to February 2020 study period, the onboard supervisor encountered several problems that reduced fishing activity. These included:

- Reports that the seines were damaged by anchor seines. (According to the Department of Fisheries of the Ministry of Agriculture, anchor seine fishing is illegal in Region 2.)
- Frequent shortages of ice due to broken ice machines in June, September, and November 2019. Three main ice distributors are in Region 2, one of which is located at the Big Bird and Sons Fish

Port Complex. Shortages of ice significantly impact activities of fisherfolk who undertake fishing trips of more than 12 hours where it is required to preserve the haul while at sea.

- There was significant accretion of mud in the channel used to travel to and from the landing site over the period late May to June 2019. This prevented the supervisor from going to sea as the water levels were too shallow. Thereafter, the landing site was inaccessible for approximately 1 week in July 2019 as the channel was being excavated.
- The onboard supervisor became severely ill and was unable to take any fishing trips for 2 weeks in July 2019.
- The sluice malfunctioned and could not be opened in January 2020 and several vessels that had moved into the canal for servicing and repairs were grounded and could not venture out to sea. The onboard supervisor's vessel was one of those remaining on the inland side of the sluice when it malfunctioned.

2.1 Target Species and Diversity

The total weights of combined hauls from the onboard supervisor's vessel over the period April 2019 to February 2020 was 7,048 kilograms (15,538 pounds). Gillbacker and snapper were the two most abundant species caught with total weights of 3,895 kilograms (8,587 pounds) and 2,796 kilograms (6,164 pounds), respectively (Figure I-1). These two species accounted for 96 percent of the total catch with gillbacker accounting for 56 percent and snapper 40 percent, respectively. The remaining 4 percent of the haul was comprised of trout, cuirass, snook, and sea patwa. The onboard supervisor reported that bycatch from his fishing activities was low because the mesh size of the drift seines used are designed to target gillbacker and snapper. As a result, only larger species and larger fishes are captured in seines. Overall, species diversity was low with only six species being recorded by the onboard supervisor, all of which were mature.

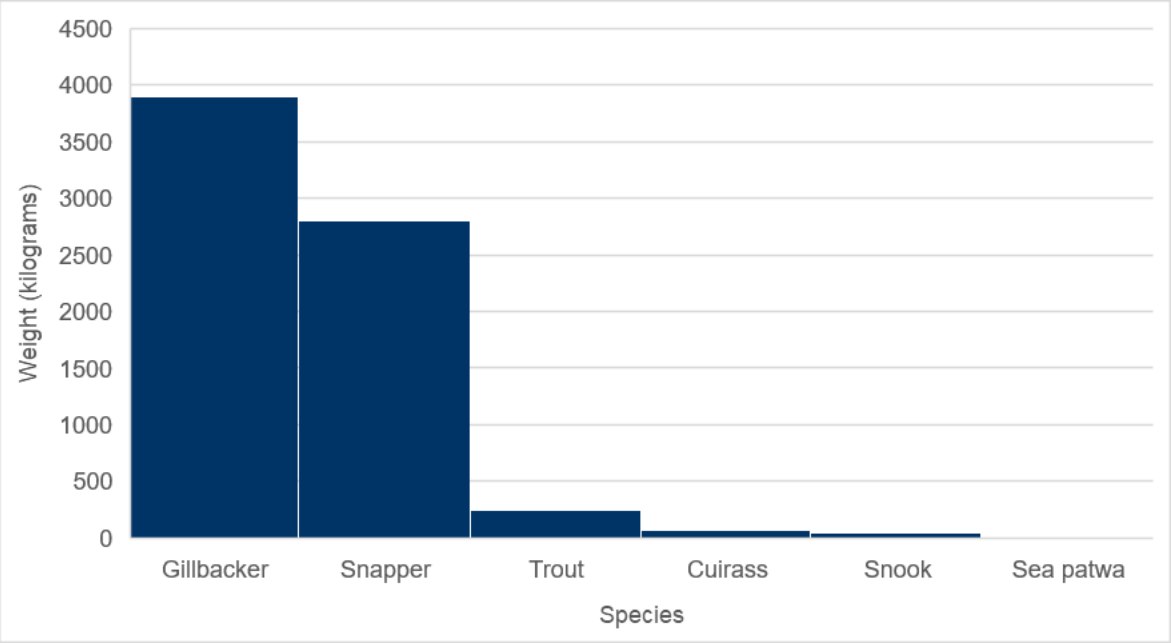

Figure I-1: Total Weight of Species Recorded by the Hampton Court Onboard Supervisor

2.2 Fishing Areas

The onboard supervisor travels in an area of 272 square kilometers. Based on the clusters of fishing points as seen on Figure I-2, the main fishing grounds cover an area of 93 square kilometers and are to the north of the landing site. The fishing points are generally fixed and the locations of fishing grounds do not change seasonally. Since the onboard supervisor is proficient in the use of GPS, he is able to use GPS to fish in the same areas that have already been marked. The onboard supervisor typically travels 11 kilometers from the landing site to fish during both seasons. However, the supervisor traveled a maximum of 15 kilometers offshore during the off-peak season and a minimum of 4 kilometers during the peak season. This aligns with fisherfolk beliefs that fishing is best conducted farther offshore in the hard season whereas fishing can be conducted closer to shore during the good season. The supervisor also recorded for the study team the waypoint of a prominent wreckage.

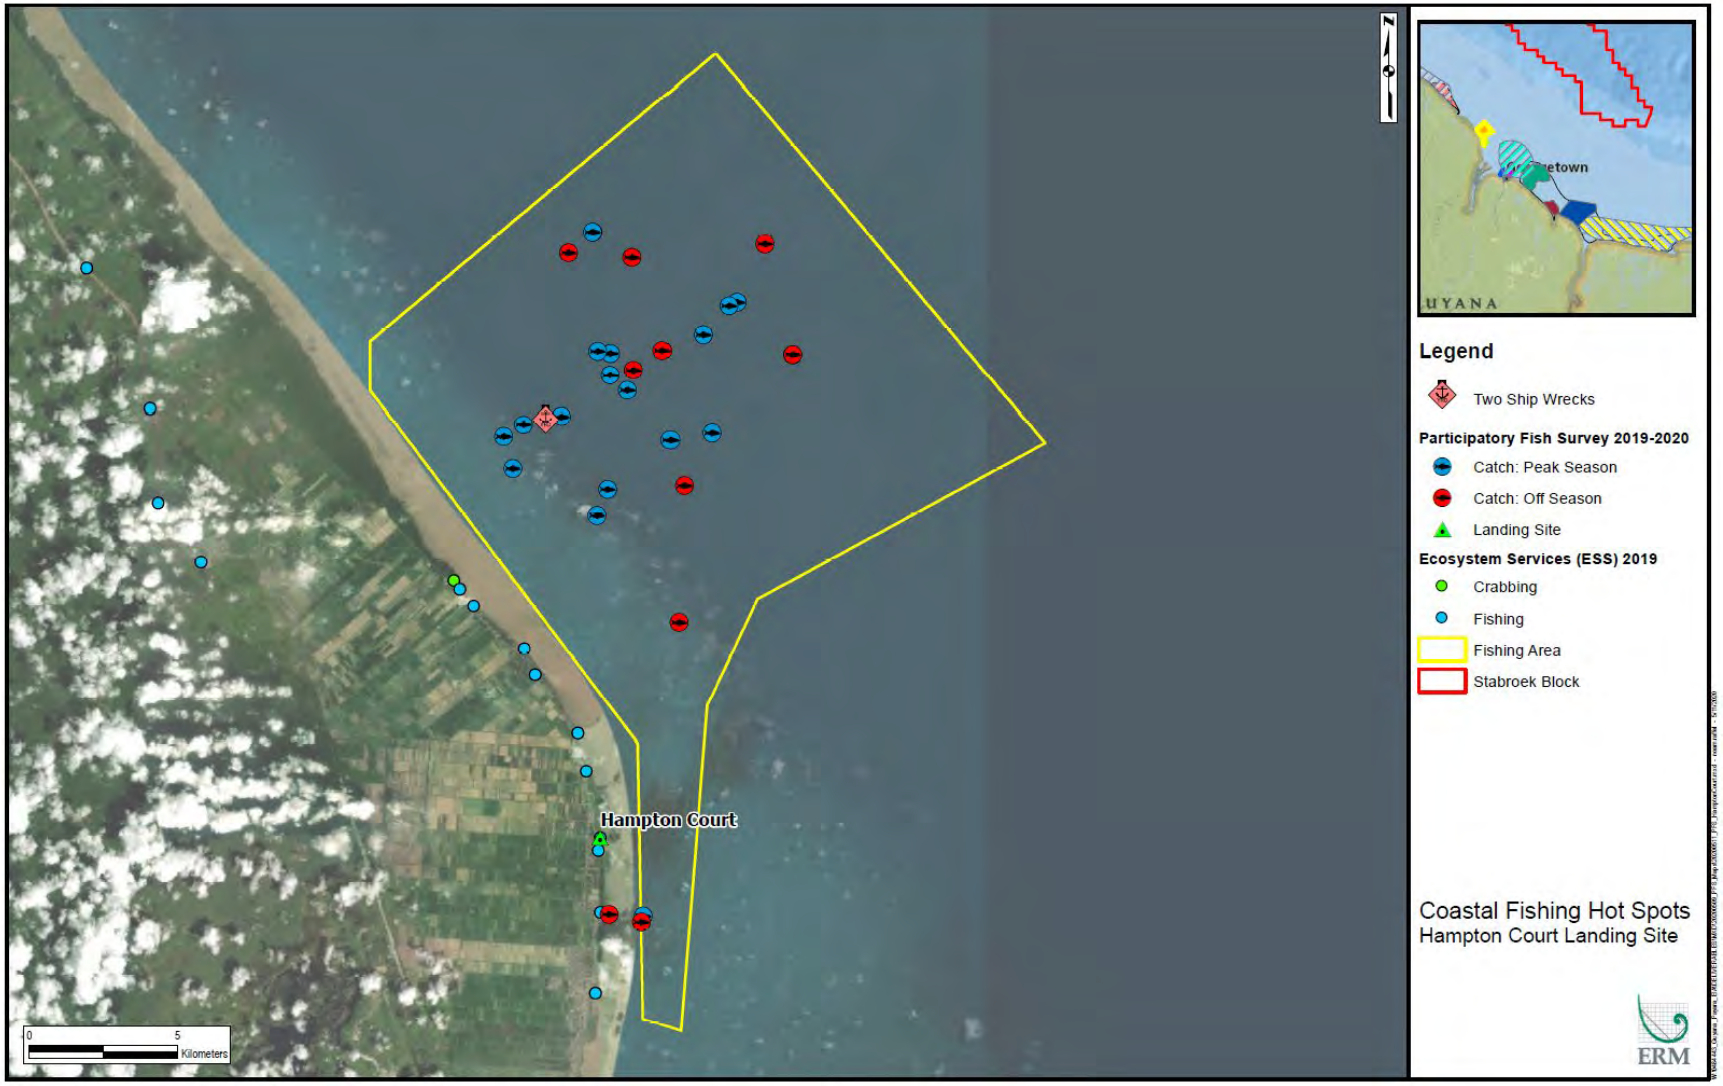

Figure I-2: Fishing Area and Fishing Points Used by the Hampton Court Onboard Supervisor

2.3 Seasonal Productivity

The onboard supervisor subscribes to the commonly-held view that fishing is most productive from May to September (the so-called “good season” that peaks in July to September) and less productive from October to March (the so-called “hard season”). It is widely believed that waters are warmer and calmer during the good season, and these conditions are more conducive to fishing. These seasons are believed to influence effort expended by fisherfolk as well as hauls per soaking of the seine and per fishing trip. The supervisor’s hauls at Hampton Court were the highest during the good season. Within the disaggregated timeframes of the good and hard seasons, hauls were higher in the rainy seasons.

The onboard supervisor spent an average of 212 hours per month fishing. There were variations in the effort expended per fishing trip on a monthly basis as seen on Figure I-3. The highest effort was expended in August 2019 with 552 hours spent fishing and June 2019 was the second highest month with 384 hours spent fishing. By contrast, the lowest effort was expended in April, May, and December 2019 with less than 100 hours spent fishing per month. Variations in effort expended seasonally were as follows:

- In the good season, lasting from May to September 2019, the average monthly effort expended was 244 hours. By contrast, the monthly effort for April 2019 and October 2019 to February 2020 was 156 hours.
- In the primary and secondary wet seasons, May to July 2019 and November 2019 to January 2020, the average monthly effort expended was 192 hours and 104 hours, respectively.
- In the primary dry season, August to October 2019, the average effort expended was 342 hours. (Data were unavailable for March 2020, so the average effort expended in the secondary dry season could not be calculated. However, it should be noted that average monthly effort expended in April 2019 and February 2020 was 144 hours.)

Seasonal trends in fishing effort during the good and hard seasons indicate that the onboard supervisor maximized effort during the peak seasons when the waters were warmer and calmer. During the hard season, it is likely that lower effort was expended because the seas were rougher, which made fishing trips shorter. Moreover, the greatest effort was recorded during the primary dry season and the second most productive season was the primary wet season. These seasons last for consecutive months of May to October and as such, there is significant overlap with the good season. Similarly, the hard season significantly overlaps with the secondary wet and dry seasons when lower effort was recorded. Greater effort during the primary dry season may be due to more favorable conditions for fishing with waters being warmer and calmer.

Overall, it may be concluded that the onboard supervisor expended the greatest effort during the good season and within that period, the greatest effort was recorded in the primary dry season. However, these trends should be approached with caution given the significant disruptions in the fishing activities by the onboard supervisor.

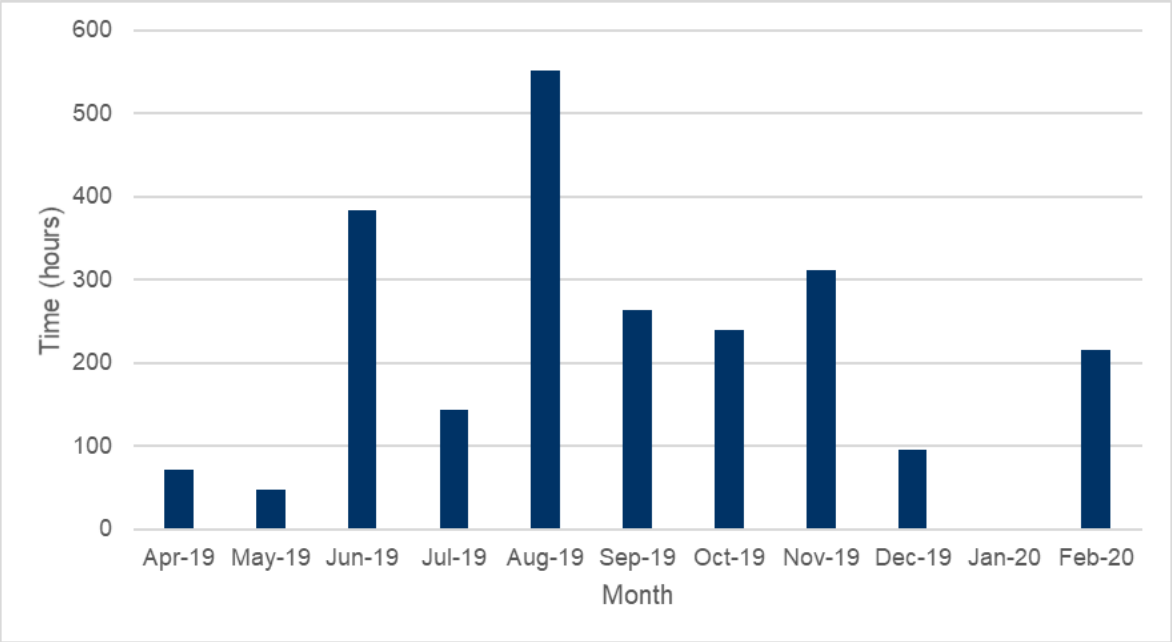

Figure I-3: Total Monthly Fishing Effort Recorded by the Hampton Court Onboard Supervisor

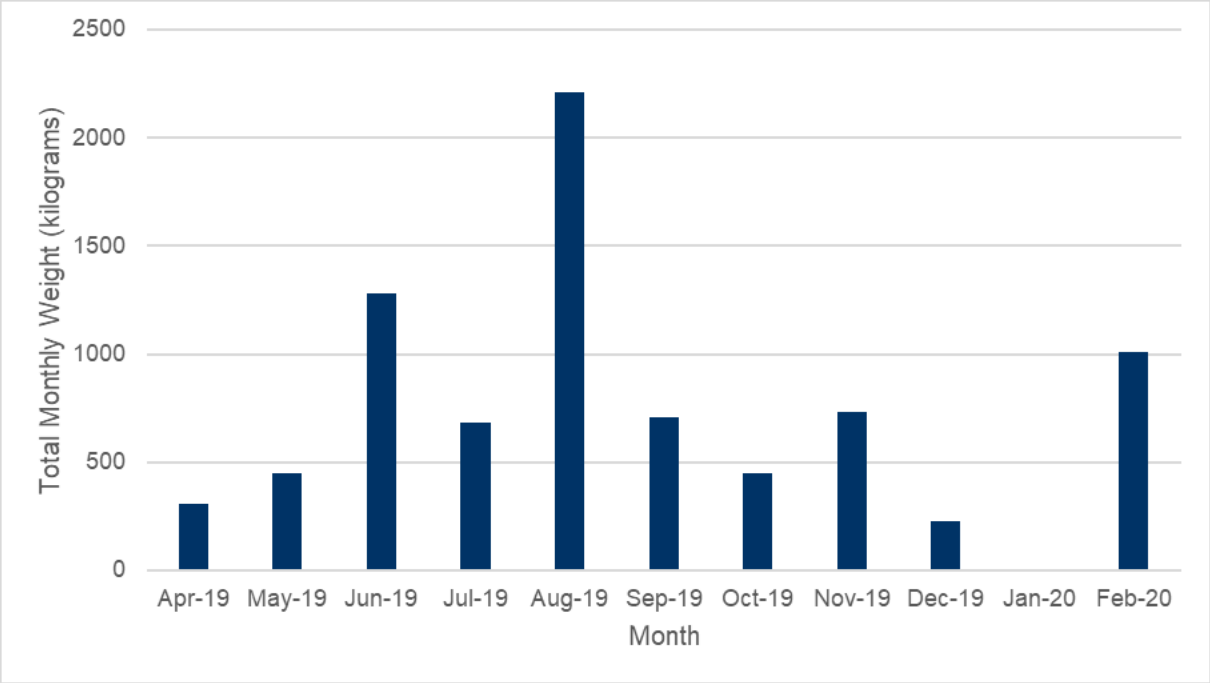

Figure I-4: Total Monthly Weight Recorded by the Hampton Court Onboard Supervisor

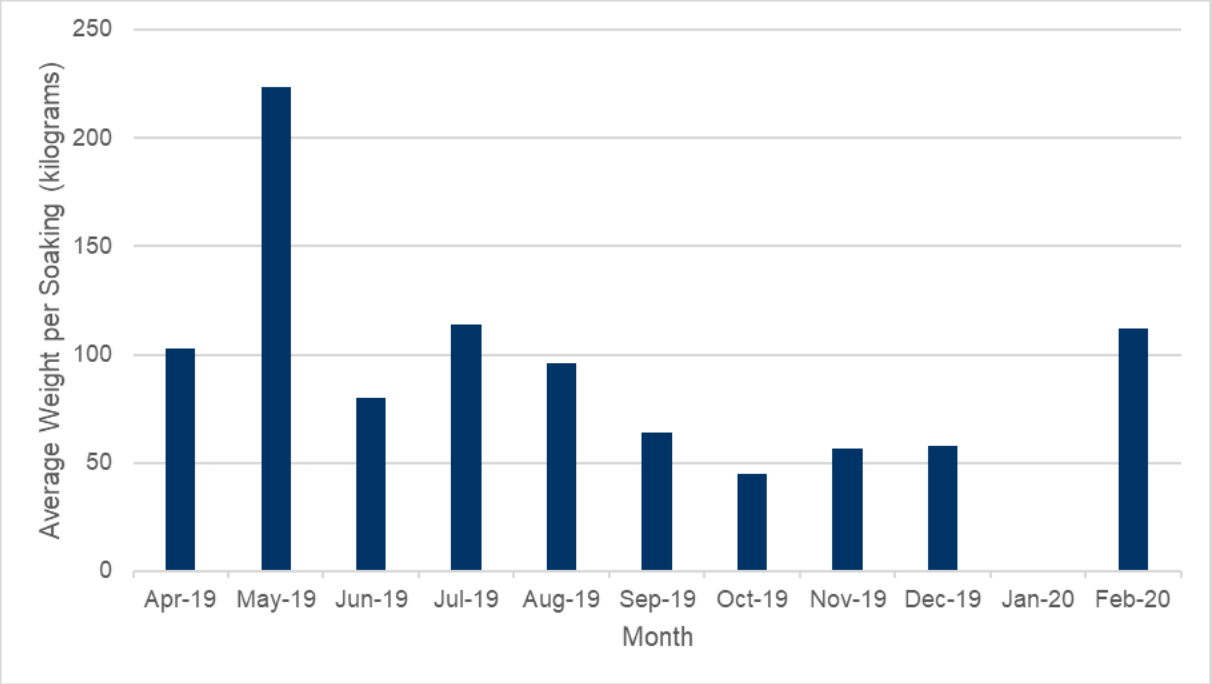

Figure I-5: Average Weight per Soaking Recorded by the Hampton Court Onboard Supervisor

Figure I-4 shows the total weight of hauls on a monthly basis and Figure I-5 shows the average haul weight per soaking of the seine. As anticipated, there were monthly variations in productivity with the following key observations:

- In the good season, lasting from May to September 2019, the combined total haul was 5,326 kilograms (11,742 pounds) with average haul per soaking of 115 kilograms (254 pounds). The highest total catch was recorded in August 2019 with 2,209 kilograms (4,870 pounds), but the average weight of hauls per soaking was lower than 100 kilograms (220 pounds). The second highest total catch was in June 2019 with 1,280 kilograms (2,822 pounds), but the average weight of hauls per soaking was 80 kilograms (176 pounds). June and August 2019 were the months in which the greatest effort were expended with 384 and 552 hours spent fishing, respectively. This indicated that the supervisor spent more days at sea and therefore, soaked the seine more frequently. It should be noted for comparison purposes that June and August were the second most productive months for the fisherfolk at the Charity landing site (Region 2) as well, and some of those fisherfolk share fishing grounds with the onboard supervisor from Hampton Court.

- In the hard season, which included April 2019 and October 2019 to February 2020, the combined total haul was 2,729 kilograms (6,016 pounds) with average haul per soaking of 74 kilograms (163 pounds). The lowest total catch was observed in April 2019 with 308 kilograms (679 pounds), but the average weight of hauls per soaking was 103 kilograms (227 pounds). This is higher than the average weight of hauls per soaking in August 2019. Similarly, in May 2019, the total weight of hauls was also low with 447 kilograms (985 pounds), but hauls per soaking were the highest of all reported months with 114 kilograms (251 pounds). In these two months, the supervisor expended significantly less effort with less than 100 hours at sea. It is likely that if the supervisor had expended greater effort in these two months, the total monthly hauls would have been higher. It should be noted that total hauls in the hard season would increase if fishing trips could have been conducted in January 2020.

By comparison, combined total weights per soaking for wet and dry seasons were as follows:

- In the May to July 2019 period, which is the primary wet season, the total haul weight was 2,411 kilograms (5,315 pounds) and the average haul per soaking was 139 kilograms (306 pounds).
- In the August to October 2019 period, which is the primary dry season, the total haul weight was 3,362 kilograms (7,412 pounds) and the average haul per soaking was 68 kilograms (150 pounds).
- In the November to January 2020 period, which is the secondary wet season, the total haul weight was 964 kilograms (2,125 pounds) and the average haul per soaking was 57 kilograms (126 pounds). (No fishing trips were conducted in January 2020 because of the sluice malfunction).
- In February 2020 and April 2019, which is the secondary dry season, the total haul weight was 1,318 kilograms (2,906 pounds) and the average haul per soaking was 107 kilograms (235 pounds). (Data were not available for March 2020 to complete the trend for this season.)

Based on the data collected, seasonal variations in average weight of soakings support fisherfolk views on the good and hard seasons for fishing activities with significant differences in total haul between these seasons. The trends in productivity during the wet and dry seasons demonstrated interesting trends. In particular, total hauls were higher in the primary and secondary dry seasons compared with the wet seasons. However, the most productive hauls were recorded in the primary wet season and the secondary dry season. These seasonal trends should be considered with caution. The challenges encountered by the onboard supervisor significantly curtailed normal fishing practices in several months for which data were collected. Further data collection is required to determine whether the trends observed thus far can be representative of fishing practices of the onboard supervisor at Hampton Court.

2.4 Biometrics

Based on the lengths and weights of fishes measured by the onboard supervisor (see Figure I-6), all species caught by the onboard supervisor had achieved sexual maturity. Many of the fishes caught are not only mature, but are also close to their maximum length. This is attributed directly to the mesh sizes of 20 centimeters (8 inches) used by the onboard supervisor.

Specifically, for the two most abundant species caught:

- The average length of snapper caught is 94 centimeters and, as seen on Figure I-7, the smallest snapper was caught in June 2019 with an average length of 83.5 centimeters. By contrast, mature lengths for snapper are 40 centimeters and total maximum length is 110 centimeters. In addition, the average lengths of the snapper caught by the onboard supervisor is significantly greater than the average length of 62 centimeters caught by the fisherfolk at the Charity landing site where snapper is the primary target species.
- The average length of gillbacker caught is 107 centimeters and, as seen on Figure I-7, the smallest average length of gillbacker caught in February 2020 had an average length of 85 centimeters. Mature gillbacker have average lengths of 46 to 59 centimeters and total maximum length is 190 centimeters.

In addition, average weights of gillbacker and snapper both peaked in August 2019, which is a month considered part of the spawning season. The onboard supervisor confirmed that eggs were also harvested from the fishes caught in August indicating that the largest fishes caught were spawning females. There was also an uptick in the sizes of snapper caught in February 2020, but this may have been an anomaly.

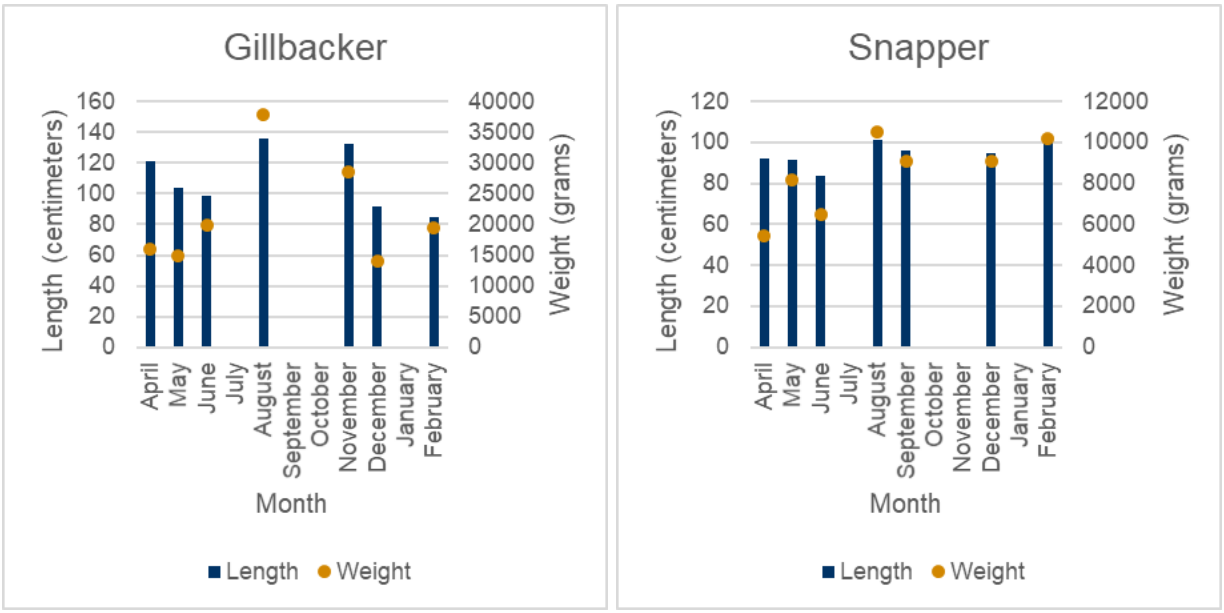

Figure I-7: Average Lengths and Weights of the Most Abundant Species Caught

3 QA/QC DATA

During the first QA/QC exercise, the study team met the onboard supervisor's vessel when it landed at the Hampton Court landing site. The supervisor had completed a 3-day fishing trip outside the mouth of the Pomeroon River. The supervisor used a drift seine with mesh sizes of 20 centimeters (8 inches). The fishing vessel used two outboard engines each of which was 48 hp. These practices were consistently reported by the onboard supervisor. The haul contained only gillbacker and snapper (see Figure I-8). The

gillbacker was already degutted, scaled, and packaged by weights. However, the study team was able to take biometric measurements of the snapper, which was also measured by the onboard supervisor. Both sets of measurements showed that the snapper was 96 centimeters in length and 9,071.84 grams in weight.

The onboard supervisor did not record any bycatch species that may have been contained in the total haul. The supervisor indicated that hauls are typically gillbacker and snapper only with occasional catches of other species such as cuirass, snook, and trout. The study team was satisfied that the onboard supervisor was accurately recording the commercial species caught and following the guidance provided in taking biometric measurements.

During the second QA/QC exercise, the team was unable to collect data from the onboard supervisor's vessel because a malfunction of the sluice had effectively grounded the vessel.

APPENDIX J LIMA (REGION 2)

1 LANDING SITE OVERVIEW

Lima is a smaller landing site in Region 2 that is used by 15 vessels that target fish and shrimp. All vessels are fitted with small outboard cruisers that have engine sizes of 10 to 25 hp. Fisherfolk indicated that several different types of gear are used, foremost of which are Chinese seines for targeting shrimp and drift seines with mesh sizes ranging from 2.54 to 15 centimeters (1 to 6 inches). Some fisherfolk also set pin seines close to the shore. These smaller vessels usually travel to preferred fishing grounds approximately 2 to 3 kilometers from the coastline and fish at depths of 4 meters. Fishing trips from this site usually range from less than 1 day to 8 days at sea with soak times of 2 to 8 hours.

Fishing with Chinese seines typically requires less effort than other types of fishing for two main reasons. Firstly, “pens” are established relatively close to the shore and therefore less time and fuel are required to travel to and from their fishing grounds than for other fishing methods. Travel to and from the pens is largely dependent on the 6-hour tidal cycles resulting in less time spent at sea than other types of fishing. Secondly, vessels that use Chinese seines have relatively low haul capacities and as a result, the duration of a fishing trip is usually shorter as vessels are not able to transport large hauls on a single trip. In general, lower hauls by weight are from pin seine and Chinese seine fishing.

Fisherfolk indicated that the main commercial species caught at the Lima landing site are cuirass, bangamary, shrimp, sea patwa, annafokes, gillbacker, and trout among others. Hauls are typically 5 to 50 kilograms (11 to 110 pounds) depending to the type of fishing gear used and the season. Fishes and shrimp are sold both at the landing site and in surrounding villages and prices range from $220 to $440 GYD ($1.06 to $2.11 USD) per kilogram.

The principal challenges encountered by fisherfolk at this landing site are conflicts with anchor seine vessels, piracy, and theft.

2 ONBOARD SUPERVISOR RESULTS

The onboard supervisor who participated in the study principally used a Chinese seine with mesh sizes of 2.54 to 10 centimeters (1 to 4 inches) to target shrimps, mainly the white belly shrimp. Fishing trips are dependent on tidal conditions. The supervisor travels to the pens to set the seine during high tide. He has three pens located approximately 5 kilometers from the shore. Each fishing trips lasts, on average, 6 hours. The onboard supervisor generally did not undertake longer trips as there was additional fishing gear he used to complement the Chinese seines on fishing trips. The onboard supervisor’s vessel has an estimated haul capacity of 500 kilograms (1,102 pounds) and he typically returns to the landing site after the seine has been hauled. He is the sole crew of his vessel. When the study started, he used a 15 hp engine but this was replaced by a 25 hp engine after the former was stolen. Fuel is the main expense as the fishing activity does not require large quantities of ice given the relatively short period spent at sea per fishing trip.

Although the Chinese seine is the principal gear used, the onboard supervisor augments fishing practices when hauls of shrimp are low. Specifically, drift seines with mesh sizes of 10 centimeters (4 inches), pin seines with mesh sizes of 10 centimeters (4 inches), and Cadell lines are all used. On some fishing trips, the supervisor uses several of these gear types at the same time. Due to these practices, the onboard supervisor showed the greatest versatility of fishing methods used of any participant in the study. However, for comparison purposes, onboard supervisors at landing sites in Windsor Forest (Region 3) and Ogle (Region 4), whose principal fishing gear was Chinese seines, were also observed to use Cadell lines while the seines were soaking.

From April 2019 to February 2020, the onboard supervisor encountered a few challenges that reduced fishing activity and hauls:

- Sargassum seaweed was abundant in April and May 2019, which significantly reduced the fishing effort expended by the supervisor during these months. Sargassum seaweed subsequently declined but became abundant again in February 2020. The sargassum seaweed was reported to drift into seines and reduce the quantities of shrimp that can be caught in the seine. Cleaning sargassum weeds from the Chinese seines is also a very time consuming process and this has been reported to last for days.

- In October 2019, while the supervisor's vessel was docked at the landing site, the engine was stolen. Due to the cost of the engine, the supervisor sought help from the Ministry of Agriculture, which replaced the engine.

2.1 Target Species and Diversity

The total weight of combined hauls from the period for which data were collected was 2,935 kilograms (6,470 pounds) from 952 hours of effort total. Shrimp was the most abundant species caught with a total weight of 870 kilograms (1,918 pounds) as seen on Figure J-1. It should be noted that the supervisor caught both white belly shrimp and corse shrimp/seabob but recorded both as "shrimps." In addition, hauls of shrimps were not separated for sale. It should be noted that although shrimp was the most abundant species caught, its percentage representation of 71 percent of total haul is typical of Chinese seine fishing. For example, based on data collected by the regional supervisor at the Zeeburg landing site (Region 3) where all vessels use Chinese seines, white belly shrimp accounted for 85 percent of the total haul. Similarly, the onboard supervisor at the Ogle landing site (Region 4) also uses Chinese seines for fishing and had total hauls of which 71 percent were corse shrimp/seabob.

Highwater and cuirass were the second and third most abundant species caught representing 23 percent and 9 percent of the haul, respectively. While the shrimp would have been caught exclusively by the Chinese seines, highwater and cuirass could be caught by any of the four fishing methods employed by the onboard supervisor. The fourth most abundant species caught was lau lau, accounting for 6 percent of the total haul. Lau lau is a freshwater fish and hauls containing this species are typically good indicators of fishing activities occurring relatively close to the shoreline. Moreover, lau lau was only caught during the primary wet season, in May and June 2019, when the salinity of nearshore waters is lowest.

Overall, 29 species were caught by the onboard supervisor including white belly shrimp and corse shrimp and several high-value species such as snapper, gillbacker, lau lau, and trout. Overall, low- to medium-value species were generally caught with greater abundance including shrimps, highwater, and cuirass. This high species diversity is likely directly related to the varied fishing methods employed since the target species of several types of fishing practiced are represented in the haul. For example, shrimps are the target species of Chinese seines; sea catfish are the target species of Cadell lines, and bangamary, butterfish, snapper, gillbacker, and trout are the target species of drift seines with a range of mesh sizes. In addition, higher species diversity is also expected from Chinese seines, which have smaller mesh sizes and typically captured most fishes including smaller species such as the Suriname mullet.

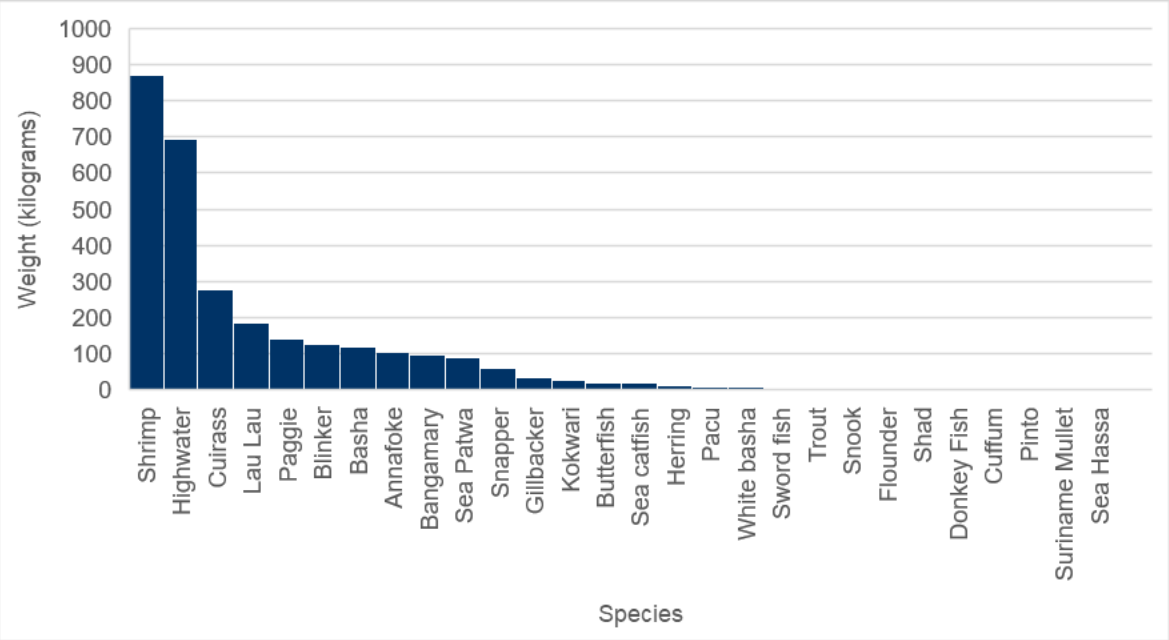

Figure J-1: Total Weight of Species Recorded at by the Lima Onboard Supervisor

2.2 Fishing Areas

The onboard supervisor had a fishing area of 20 square kilometers as depicted on Figure J-2. The supervisor uses three different fishing points based on the different types of fishing gear. The fishing point located closest to the shore was 0.23 kilometers offshore and was used to set the pin seines. This point was only used during the October to February period, which is considered the hard season for artisanal fishing. The other two fishing points are both located approximately 1.37 kilometers offshore and represented the locations of the onboard supervisor's pens used for soaking the Chinese seines. On occasions when the onboard supervisor uses drift seines, they are set in locations proximate to the Chinese seine fishing points.

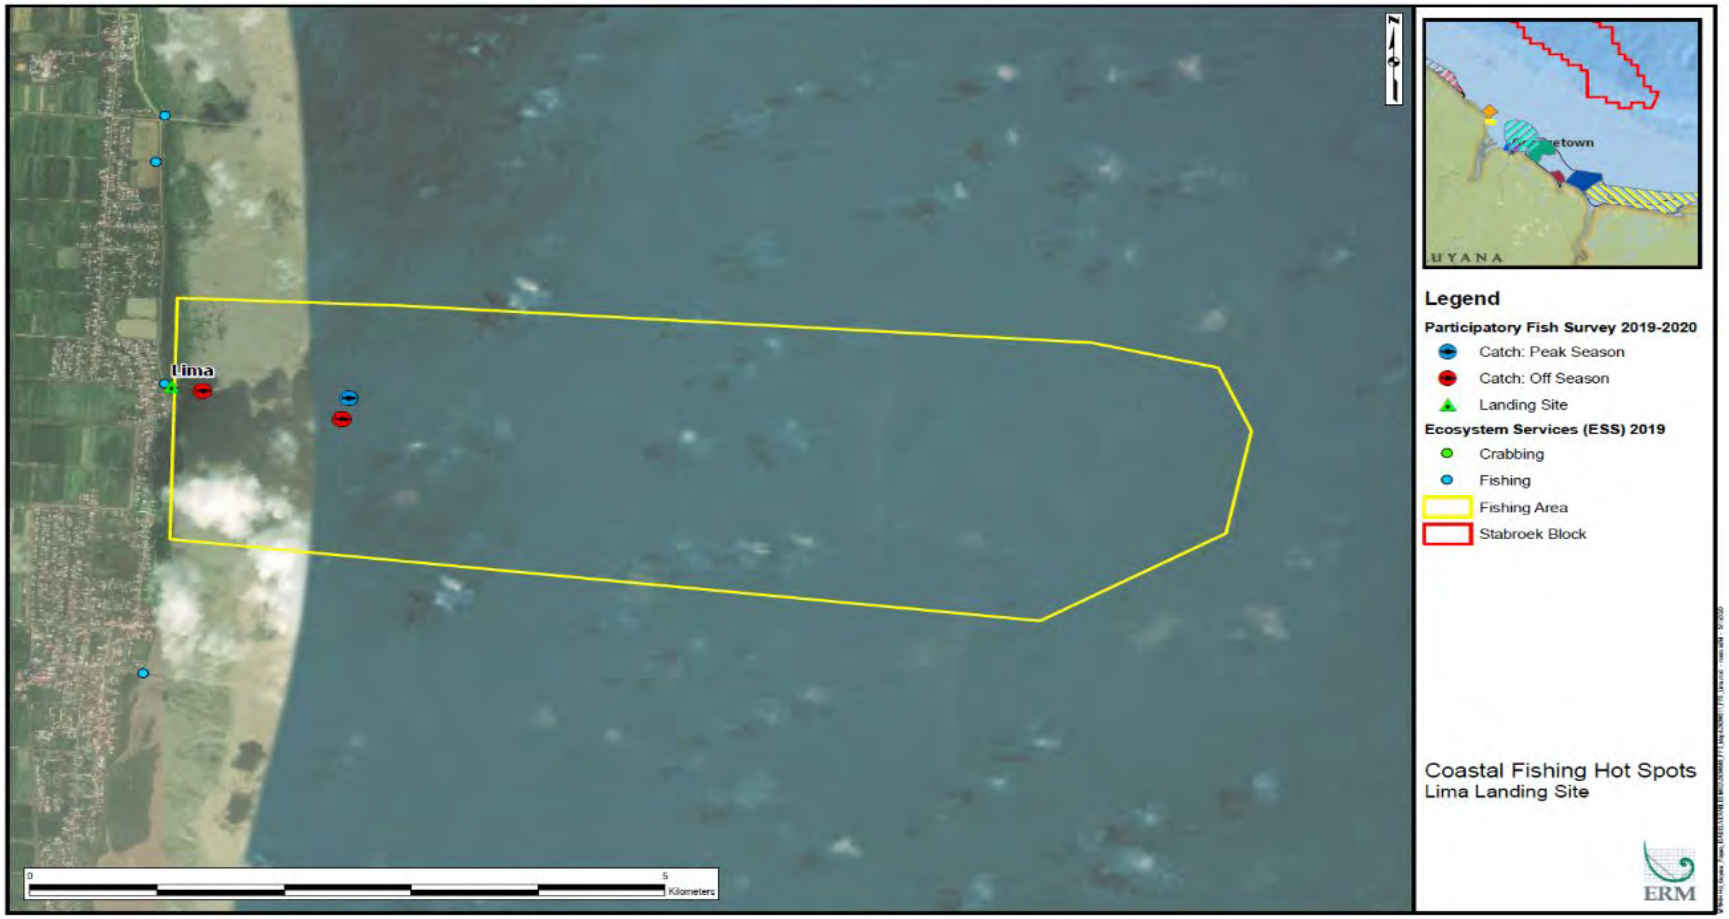

Figure J-2: Fishing Area and Fishing Points Used by the Lima Onboard Supervisor

2.3 Seasonal Productivity

The onboard supervisor subscribes to the commonly-held view that fishing is most productive from May to September (the so-called “good season” that peaks in July to September) and less productive from October to March (the so-called “hard season”). It is widely believed that waters are warmer and calmer during the good season, and these conditions are more conducive to fishing. However, fisherfolk have varying beliefs on the most productive months for shrimping. At the Zeeburg landing site (Region 3), some fisherfolk indicated that shrimp catch generally increases during the closed trawl season, which occurs from 16 August to 5 October annually, and may allow more shrimp to come closer to the shore. Other fisherfolk indicate that the average productivity increases during the dry seasons of February to April and August to September because the waters are generally more saline compared to the wet season. Another common belief is that shrimp productivity increases during the spawning seasons of January to April and June to July (Pereira et al. 2017) when shrimp come closer to shore to spawn in the mangroves. By virtue of the varied fishing methods practiced by the onboard supervisor, it is unlikely that there are clear seasonal trends in either effort or hauls.

The onboard supervisor spent an average of 86 hours at sea per month. As seen on Figure J-3, the greatest effort was expended in November 2019 and January 2020 with 155.5 and 128.5 hours, respectively. By contrast, the lowest effort was expended in December 2019 when 40 hours were spent fishing. Although 7.5 hours were expended in April 2019, data collection did not begin until 23 April 2019, and as such, there is no comparable monthly data pool for this month.

As seen on Figure J-4, the highest average catch per soaking was recorded in February 2020 with 28 kilograms (62 pounds) and in June 2019 with 24 kilograms (53 pounds). The lowest average catch per soaking was observed in May and August 2019 with 12 kilograms (26 pounds) and 15 kilograms (33 pounds), respectively. The greatest total hauls were observed in November and July 2019 with 475 kilograms (1047 pounds) and 421 kilograms (928 pounds), respectively. Low total hauls were observed in May, August, and December 2019 with 169 kilograms (372 pounds), 176 kilograms (388 pounds), and 125 kilograms (276 pounds), respectively. The lowest total haul was seen in April 2019 but as previously noted, data collection started in the final week of the month.

Seasonal comparisons of effort expended by the onboard supervisor and the hauls recorded are as follows:

- In the May to September 2019 good season, the total average weight of hauls was 1,412 kilograms (3,113 pounds) with 481 hours spent at sea. On average, soaking of the seine during this period yielded 18 kilograms (40 pounds).
- In the October 2019 to February 2020 hard season, the total weight of hauls was 1,499 kilograms (3,304 pounds) with 463 hours spent at sea. On average, soaking of the seine during this period yielded 21 kilograms (46 pounds).

Additional seasonal trends at this landing site are as follows:

- In August to October 2019, the primary dry season and the closed trawl season, the total weight of hauls was 643 kilograms (1,418 pounds) with 256.5 hours spent at sea. On average, soaking of the seine during this period yielded 17.5 kilograms (39 pounds).
- In February 2020 and April 2019, two months of the secondary dry season, soaking of the seine during this period yielded, on average, 24 kilograms (53 pounds). Total effort and hauls were not presented for this period because the data pool for April 2019 is relatively small, and data were not able to be retrieved for March 2020 to complete this season.

- In April 2019 and January and February 2020, three of the four months of the first shrimp spawning season, soaking of the seine yielded, on average, 22 kilograms (49 pounds). Similarly, total effort and hauls were not presented for this period because the data pool for April 2019 is relatively small and data were not able to be retrieved for March 2020 to complete this season.
- In the June to July 2019 period, the second shrimp spawning season, the total weight of hauls was 802 kilograms (1,768 pounds) with 108 hours spent at sea. On average, soaking of the seine during this period yielded 22 kilograms (49 pounds).
- In May to July 2019, the primary wet season, total weight of hauls was 971 kilograms (2,141 pounds) with 285 hours spent at sea. On average, soaking of the seine in this period yielded 19 kilograms (42 pounds). In addition, the two most productive months, May and July, were part of this season.
- In November 2019 to January 2020, the secondary wet season, the total weight of hauls was 965 kilograms (2,127 pounds) with 324 hours spent at sea. On average, soaking of the seine during this period yielded 19 kilograms (42 pounds).

Based on the data collected, productivity at this landing site did not follow the good and hard seasons that were identified by fisherfolk. In fact, productivity was higher during the hard season but the difference in total hauls was not significant. Greater effort was expended during the May to September period when the total hauls and productivity per soaking were lower, but the differences in effort and productivity between the good and hard seasons were relatively small. The results may indicate the seasonality of shrimping is different than it is for fishing, but the variety of gear types used and the large number of fish species caught by the supervisor makes it difficult to attribute these results to any specific cause.

Moreover, interesting trends were observed in the other seasons for which productivity was considered. The greatest effort was expended during the wet seasons and the second spawning season. Total hauls during these seasons were higher than the total haul during the primary dry season and other seasons for which trends were examined. The greatest effort was expended in the secondary wet season while the lowest effort was expended in the second spawning season. However, the most productive haul per soaking was observed in the secondary dry season. The second highest hauls per soaking were recorded in both shrimp spawning seasons. It is interesting to note that there is a significant overlap of the first spawning season (January to April) and the secondary dry season (February to April). As such, based on the information collected, the most productive periods for the onboard supervisor's fishing practice were both of the shrimp spawning seasons. The first shrimp spawning also overlaps with the secondary dry season and the productivity was also higher during this time. However, this should be considered with caution given that the onboard supervisor did not exclusively use Chinese seines in the fishing practice during the study period and that gaps in some of the data collected may also influence this conclusion.

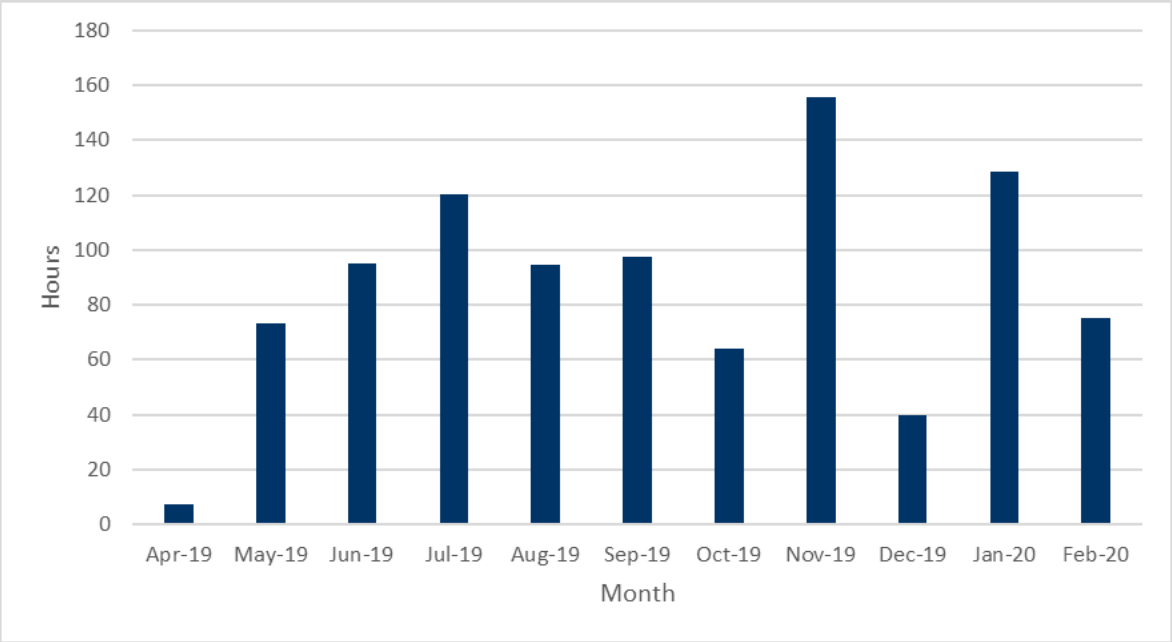

Figure J-3: Total Monthly Fishing Effort Recorded by the Lima Onboard Supervisor

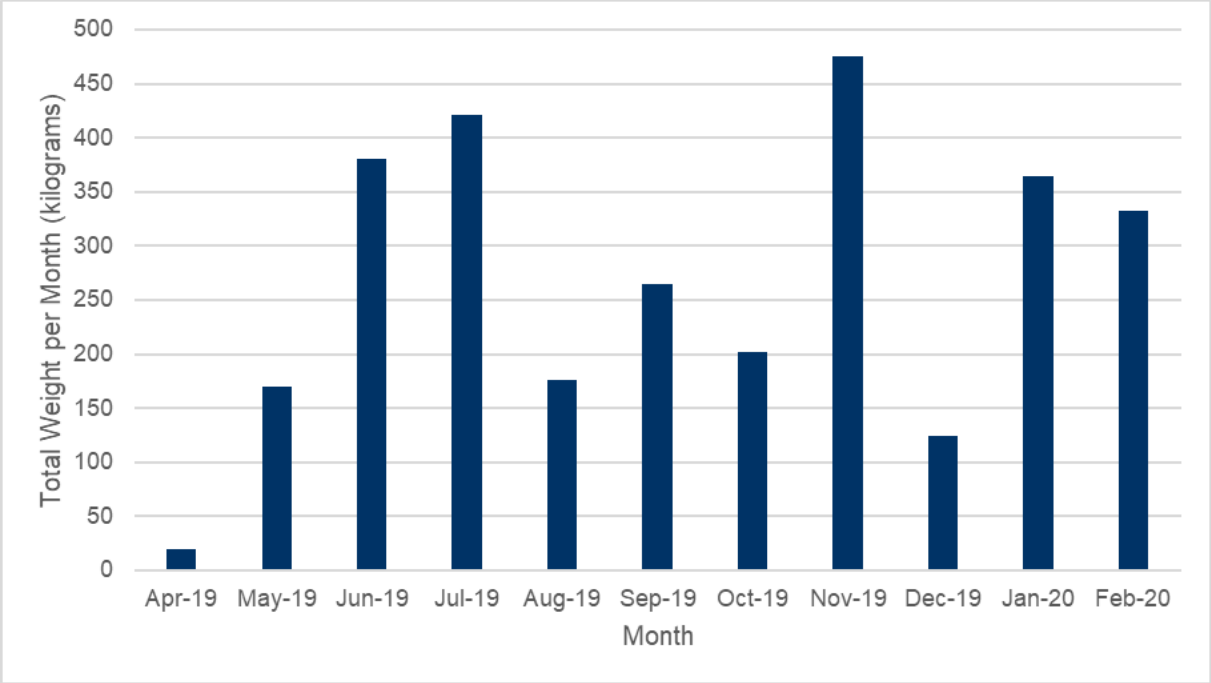

Figure J-4: Total Weight of Species Recorded by the Lima Onboard Supervisor

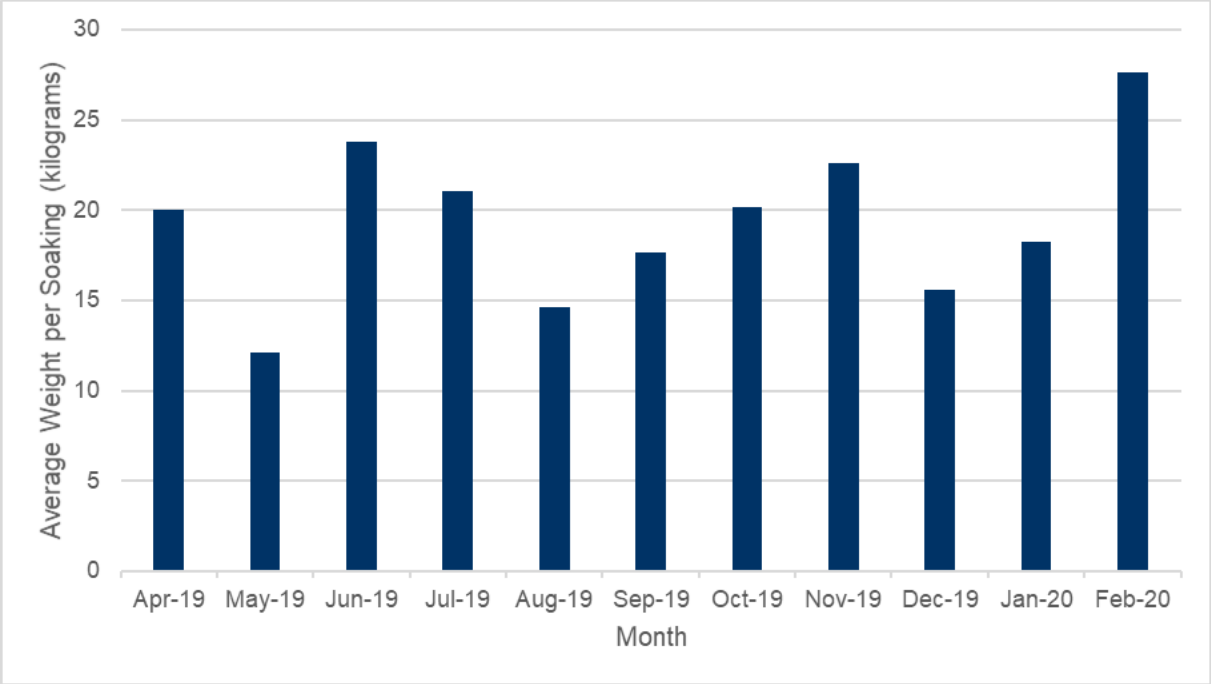

Figure J-5: Average Weight per Soaking Recorded by the Lima Onboard Supervisor

2.4 Biometrics

The onboard supervisor measured the average lengths and weights of representative fishes of the species caught. Both mature and immature fishes were caught. The mature species included gillbacker, lau lau, cuffum, cuirass, blinker, and pacu, which were all considered to be mature at 79, 78, 76, 61, 47, and 34 centimeters, respectively. It is likely that these fishes were caught by the fishing methods other than the Chinese seine because the mesh sizes would generally not allow for capture of the larger fishes. Other mature species included shad, flounder, and annafokes, which could have been captured by all other seine types. None of the other 12 species caught had achieved maturity. Biometric data were not collected for the shrimp, which is the target species of the Chinese seine fishing type. However, lengths of white belly shrimp measured by the study team during site visits ranged from 4 to 6 centimeters and this is considered mature. Since the onboard supervisor used a series of different fishing methods, the comparison of average monthly weights and lengths of the most abundant species caught would reflect no defined trends (see Figure J-6).

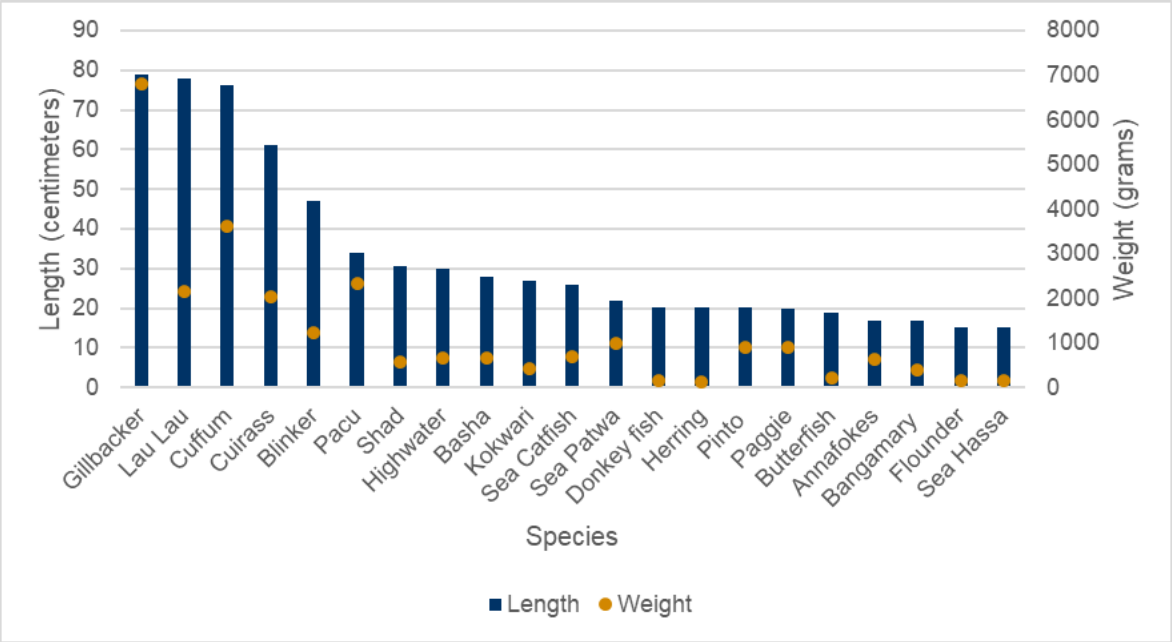

Figure J-6: Average Length and Weight of Fishes Caught by the Lima Onboard Supervisor

3 QA/QC DATA

During the 3-day period for which the QA/QC exercise was conducted in Region 2 in September 2019, neither the onboard supervisor, nor any of the other fisherfolk operating at the Lima landing site, went to sea. This was due to a spring tide causing the seas to be too rough for smaller Chinese seine vessels to conduct fishing activities. As a result of these circumstances, the QA/QC exercise could not be conducted for the Lima onboard supervisor.

During the second QA/QC exercise, the supervisor's haul was recorded. However, the onboard supervisor had a "bust trip" because hauls were significantly lower than what is typically obtained. During the trip assessed, the onboard supervisor used drift seines with mesh sizes of 10 and 13 centimeters (4 and 5 inches). However, only three highwater were caught by the onboard supervisor. Although low, these data were consistent with data collected by the onboard supervisor during other unsuccessful fishing trips. Overall, the study coordinator was satisfied that the onboard supervisor was accurately recording the commercial species caught and following the guidance provided in taking biometric measurements.

APPENDIX K ZEEBURG (REGION 3)

1 LANDING SITE OVERVIEW

Zeeburg is one of the largest landing sites in Region 3 and is used almost exclusively by vessels equipped with 30 hp outboard cruisers for Chinese seine fishing. Fisherfolk estimate that over 30 vessels use this site with Chinese seines that have mesh sizes of 1.27 to 10.16 centimeters (0.5 to 4 inches). The target species of the Chinese seines used at this landing site is the white belly shrimp. The landing site is also used to dry the white belly shrimp. The drying process involves cleaning the shrimp (locally referred to as “picking shrimps”) and removing the carapace, tail, swimerettes, and occasionally the shell from the abdomen. The shrimp is then steamed over open fire pits placed on concrete pads at the landing site. The steamed shrimp is then laid out on a concrete surface, normally the seawall, during sunny conditions. There are ready markets for fresh and dried shrimp as trucks visit the landing site on a daily basis to purchase the catch. Some of these trucks source the shrimp directly from women in the village who are involved in the “picking shrimp” process.

In July to September 2019, major infrastructural works were conducted by the government at the landing site to replace the Zeeburg seawall with rip-rap (see Figure K-1 on left). Fisherfolk indicated that their fishing activities were affected during the construction period as construction materials were stockpiled on areas of the seawall used for storing fishing gear and drying shrimp. With the installation of the rip-rap, all concrete surfaces were demolished and the landing site was frequently muddy. After construction, fisherfolk continued to experience challenges as severe overtopping during the spring tides in September 2019 resulted in significant, unprecedented damage to the landing site as the areas intended to be used for drying shrimp were covered with mud (see Figure K-1 on right). This situation was further exacerbated by heavy rainfall. This reduced drying activity at the site and forced a temporary stoppage of work at the landing site in October 2019 as fisherfolk tried to rehabilitate some sections of the landing site and the concrete pads to be used for drying shrimp, as well as installing channels to drain water that had accumulated behind the seawall after the overtopping events. Most fisherfolk contended that the rip-rap were less effective than the original sea walls in preventing overtopping at the site.

Fisherfolk reported further challenges related to the theft of fishing equipment stored at the landing site and pirate attacks when at sea.

Figure K-1: Installation of Rip-Rap and Seawall Demolition (Left) and Aftermath of Overtopping (Right)

2 REGIONAL SUPERVISOR RESULTS

One regional supervisor participated in the study and he provided the results in this section over the course of the study period.

2.1 Effort and Haul

Based on the data collected, white belly shrimp was the most abundant species caught by weight with 111,535 kilograms (245,892 pounds) accounting for 85 percent of the total haul at the landing site (see Figure K-2). Bangamary, cuirass, and mullet were the second, third, and fourth most abundant species caught with 8,115 kilograms (17,890 pounds), 6,681 kilograms (14,729 pounds), and 2,365 kilograms (5,213 pounds), respectively. In total, recorded hauls at this landing site had a total weight of 130,656 kilograms (288,047 pounds).

Fisherfolk travel distances ranging from 5 to 30 kilometers from the landing site to “pens” along the shorelines of Region 2 and 3, and around Leguan Island at the mouth of the Essequibo River. Chinese seines are set in the pens at depths of approximately 5 to 30 meters and are soaked one to two times for approximately 4 to 6 hours per fishing trip. Typically, these vessels are staffed by two to three crew members. Over the study period, a trip lasted for 7 hours on average. Figure K-3 shows the average number of hours for which seines were soaked on a monthly basis and represents the average monthly effort for fisherfolk at this landing site. The following trends were observed in the effort expended on a monthly basis:

- The shortest average trips lasted for less than 7 hours and were observed in May to July 2019, September 2019, and again from November 2019 to January 2020. Of these, the shortest trips were observed in consecutive months from May to July 2019. The periods May to July and November to January are Guyana’s primary and secondary wet seasons. Lower effort in September 2019 was directly related to damage at the landing site resulting from spring tides, which curtailed and consequently, temporarily stopped activities at the landing site in October.

- The longest average trips lasted for more than 7 hours and were observed in April and August 2019, and again in February 2020. In addition, trips with average lengths of more than 8 hours were observed in April 2019 and February 2020. It is likely that these longer trips were as a result of the seines being soaked more than once per fishing trip. Additional data are needed to better understand the factors that influence multiple soakings per trip including haul per soaking and fisherfolk perception of seasonal influence.

No data on fishing effort in the dry seasons were collected at this landing site because activities at the landing site were curtailed in the primary dry season (August to October 2019). In addition, data were not available from the regional supervisor for March 2020 to show any trends in fishing activities for the February to April secondary dry season.

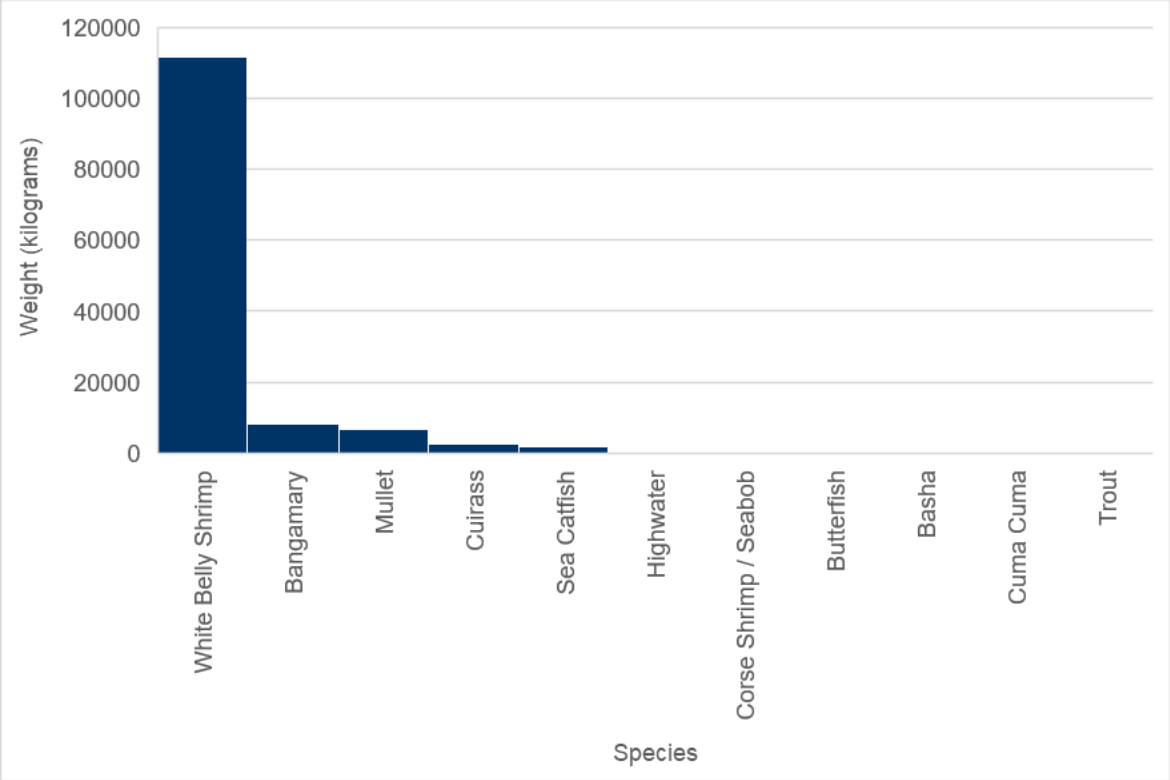

Figure K-2: Total Weight of Species Caught at the Zeeburg Landing Site

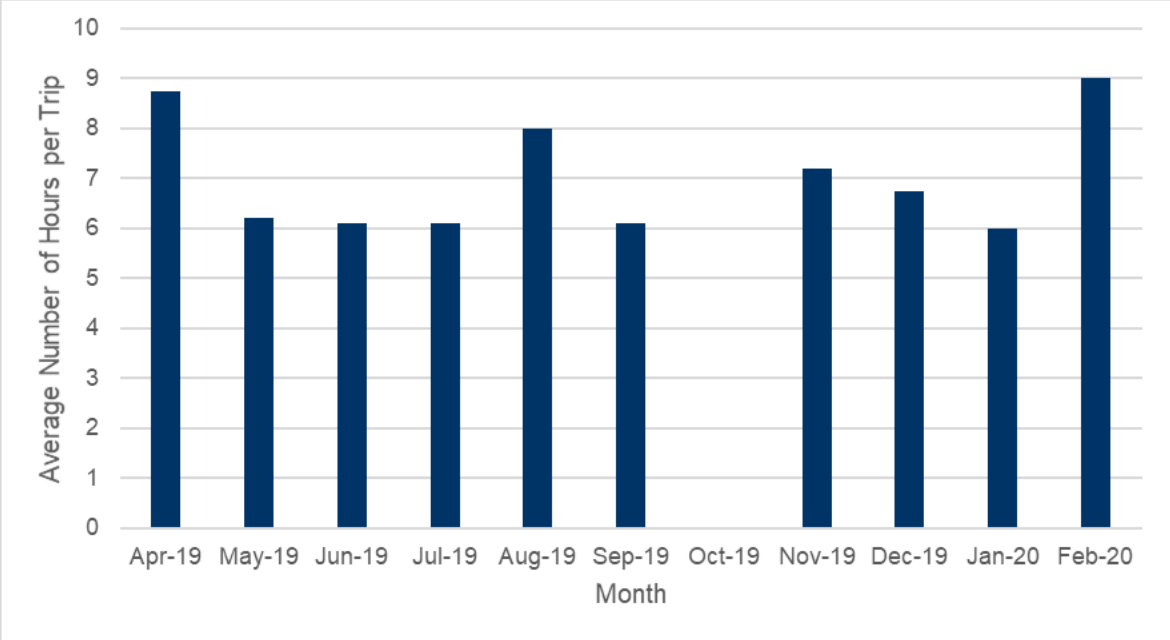

Figure K-3: Average Monthly Fishing Effort at the Zeeburg Landing Site

2.2 Target Species and Diversity

Eleven species were caught by the regional supervisor (see Figure K-4). This number is unusual as Chinese seine fishing typically has greater species diversity in reported hauls (see data in Appendices J,

M, and O, respectively, for species composition of hauls from onboard supervisors at landing sites in Lima (Region 2), Windsor Forest (Region 3), and Ogle (Region 4) who all use Chinese seines. In addition, during visits to the landing site, the study team observed significant quantities of bycatch in hauls including fish species such as banjaman and rockhead, and non-fish species such as jellyfish. The regional supervisor indicated that data are only collected for species and fishes that are considered commercial at this landing site and therefore no bycatch was recorded by the regional supervisor. As such, it is likely that species diversity of the haul is higher than reported and also that bycatch includes juveniles of commercial species, like bangamary.

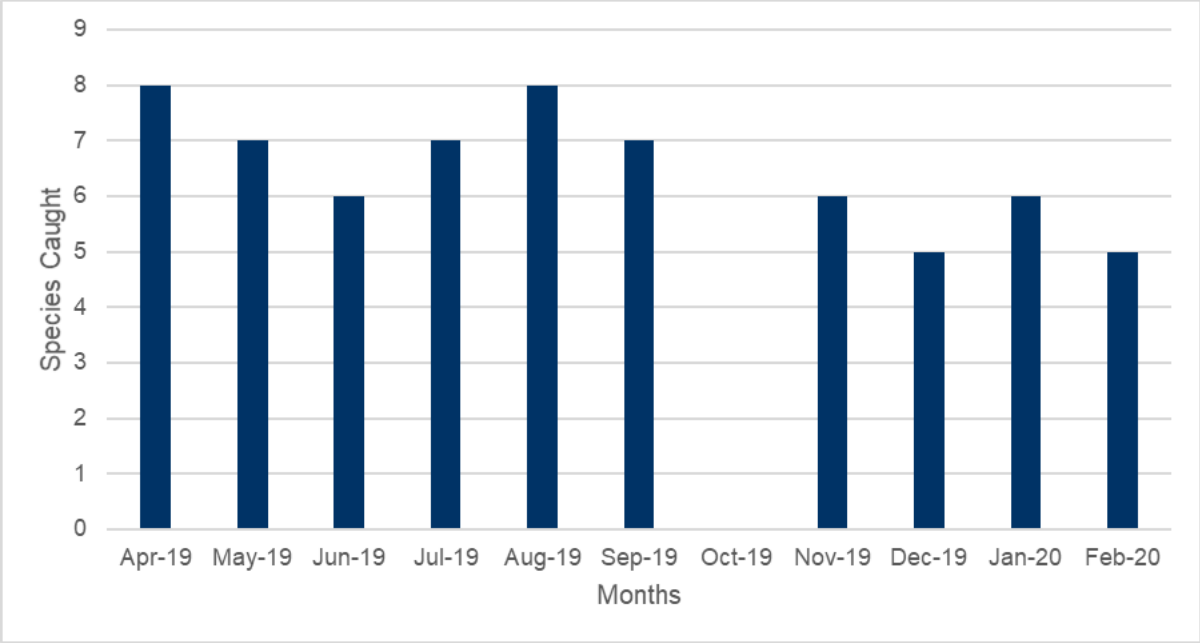

Figure K-4: Species Diversity at the Zeeburg Landing Site

2.3 Seasonal Productivity

Artisanal fisherfolk believe that the peak and off-peak seasons for fishing occur from May to September and October to April, respectively. However, fisherfolk have differing beliefs on the most productive months for shrimping. The general consensus is that shrimp catch increases during the closed trawl season, which occurs from August 16 to October 5 annually and may allow more shrimp to come closer to the shore. Some fisherfolk also believe that the average productivity increases during the dry seasons in response to the white belly shrimps' spawning activity, which occurs from January to April and June to July (Pereira et al. 2017). Spawning seasons may also increase productivity as white belly shrimp may travel closer to shore to spawn in the mangroves. Figure K-5 shows average monthly productivity, calculated as total monthly productivity divided by total number of fishing trips taken per month. The following seasonal trends were observed:

- The least productive period was the secondary wet season of November 2019 to January 2020 with a combined average productivity of 92 kilograms (202 pounds). Of these months, the lowest productivity was observed in January 2020 with a productivity of 70.5 kilograms (155 pounds). Effort expended per fishing trip consistently declined over this period and reached the lowest point in January 2020.

- Productivity was also relatively low in the primary wet season in May to July 2019 with a combined average productivity of 174 kilograms (383 pounds). During this period, fisherfolk also consistently expended lower effort with each trip lasting for 6 hours on average.
- The two most productive months were April and August 2019 with average productivity of 268 kilograms (590 pounds) and 247 kilograms (545 pounds). The most productive months are part of the primary and secondary dry seasons, part of the closed trawl season, and April is part of the first spawning season. These were among the months in which the greatest effort was expended per trip. It may be assumed that fisherfolk increased efforts in these two months because productivity was observed to be greater per trip.

Disruptions to the activities in September and October 2019 and challenges in collecting data from the regional supervisor in March 2020 have hindered the emergence of any clear trends for productivity in the dry seasons (August to October and February to March), the closed trawl season, and the January to April spawning season. Additional data are required to better understand seasonal productivity of white belly shrimping.

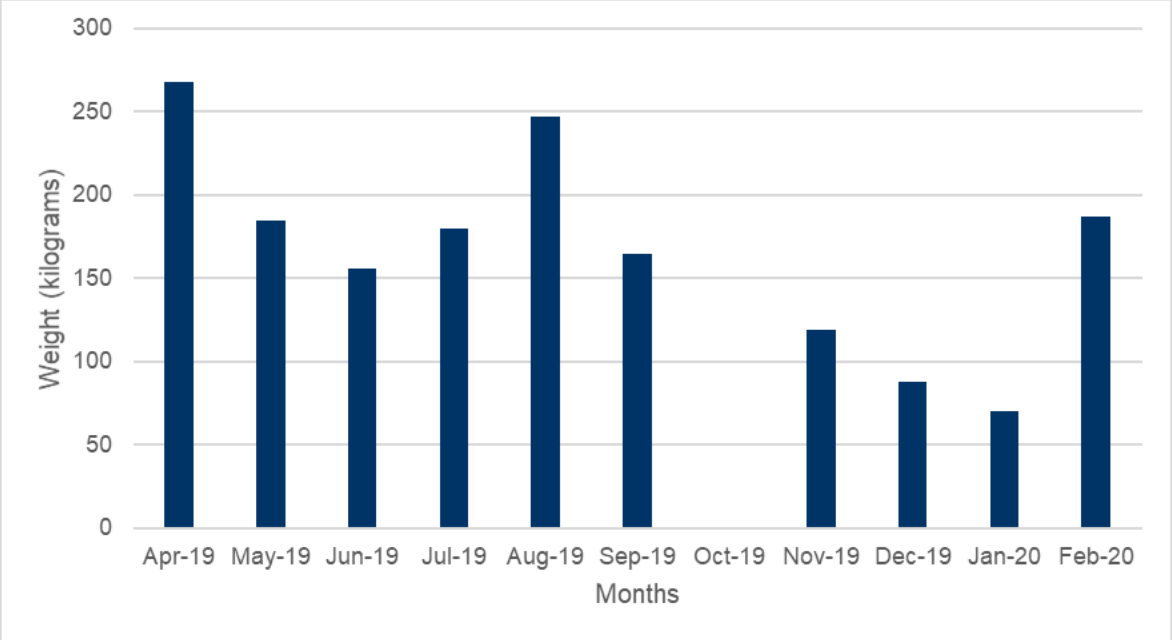

Figure K-5: Average Monthly Productivity of Fishing Trips at the Zeeburg Landing Site

2.4 Prices and Markets

Based on the data collected by the regional supervisor, cuma cuma was the highest-value fish with an annual average price of $331 GYD per kilogram ($1.60 USD per kilogram) as seen on Figure K-6. This fish is rarely caught at this landing site with a total haul weight of 4.5 kilograms (10 pounds) over the April 2019 to February 2020 period, and this may have contributed to the high price for which it was sold. The second, third, and fourth most abundant species caught were basha, corse shrimp/seabob, and trout. White belly shrimp, which is the target species and most abundant species caught, was the fifth most expensive species caught with an annual average price of $261 per kilogram ($1.30 per pound). Overall, hauls recorded at this landing site were valued at a total of $31,295,960 GYD ($150,461 USD).

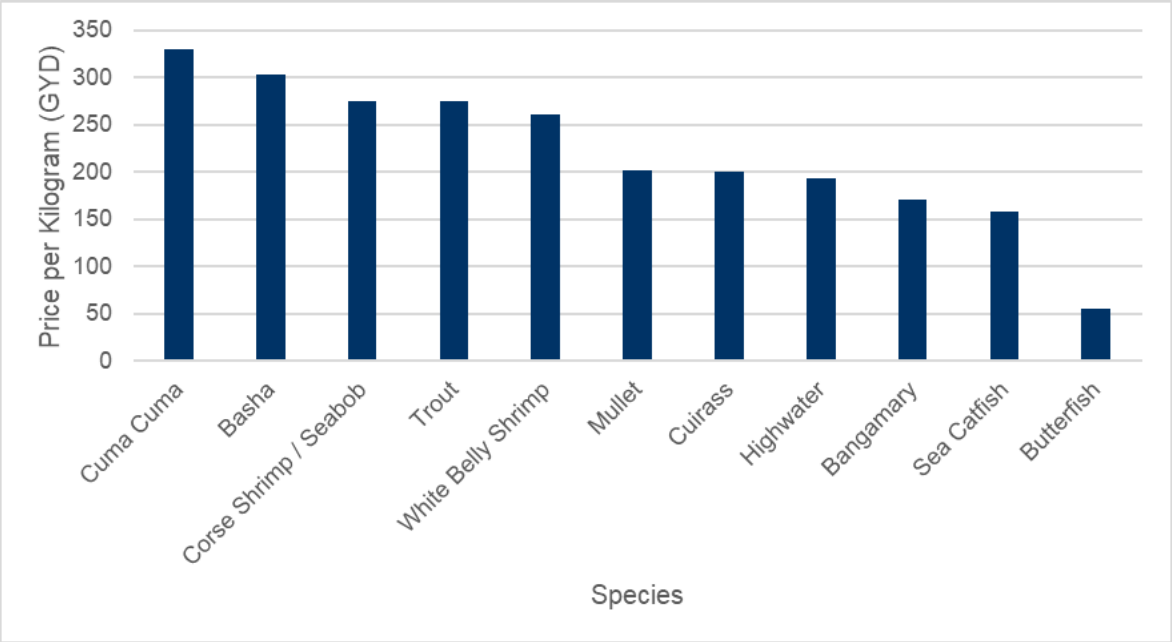

Figure K-6: Annual Average Prices per Kilogram of Fishes and Shrimps at the Zeeburg Landing Site

There are significant differences in the monthly minimum and maximum prices for the four most abundant species caught (see Figure K-7). Generally, fishes like trout, bangamary, and butterfish, among others, are less expensive at this landing site than at other landing sites, which may be due to the small size of the fishes for which there is typically less demand. Despite the differences in the minimum and maximum prices, average prices for bangamary were stable throughout the year because there are ready markets for “flat,” “fine,” or “shine” bangamary, which are the juveniles of this species. However, similar markets for juveniles of other species such as cuirass and trout do not exist and the smaller fishes of these species are typically not sought commercially.

In addition, most of the white belly shrimp is sold to vendors called huskers, who visit the landing site with trucks to purchase catch from fisherfolk and are known to bargain with fisherfolk for lower prices. Scarcity also influenced prices at this landing site as average and maximum prices for white belly shrimp, bangamary, and cuirass were among their highest in November 2019 to January 2020, which was also the least productive period. It is likely that these trends in pricing would also have been observed for all other species caught at this landing site.

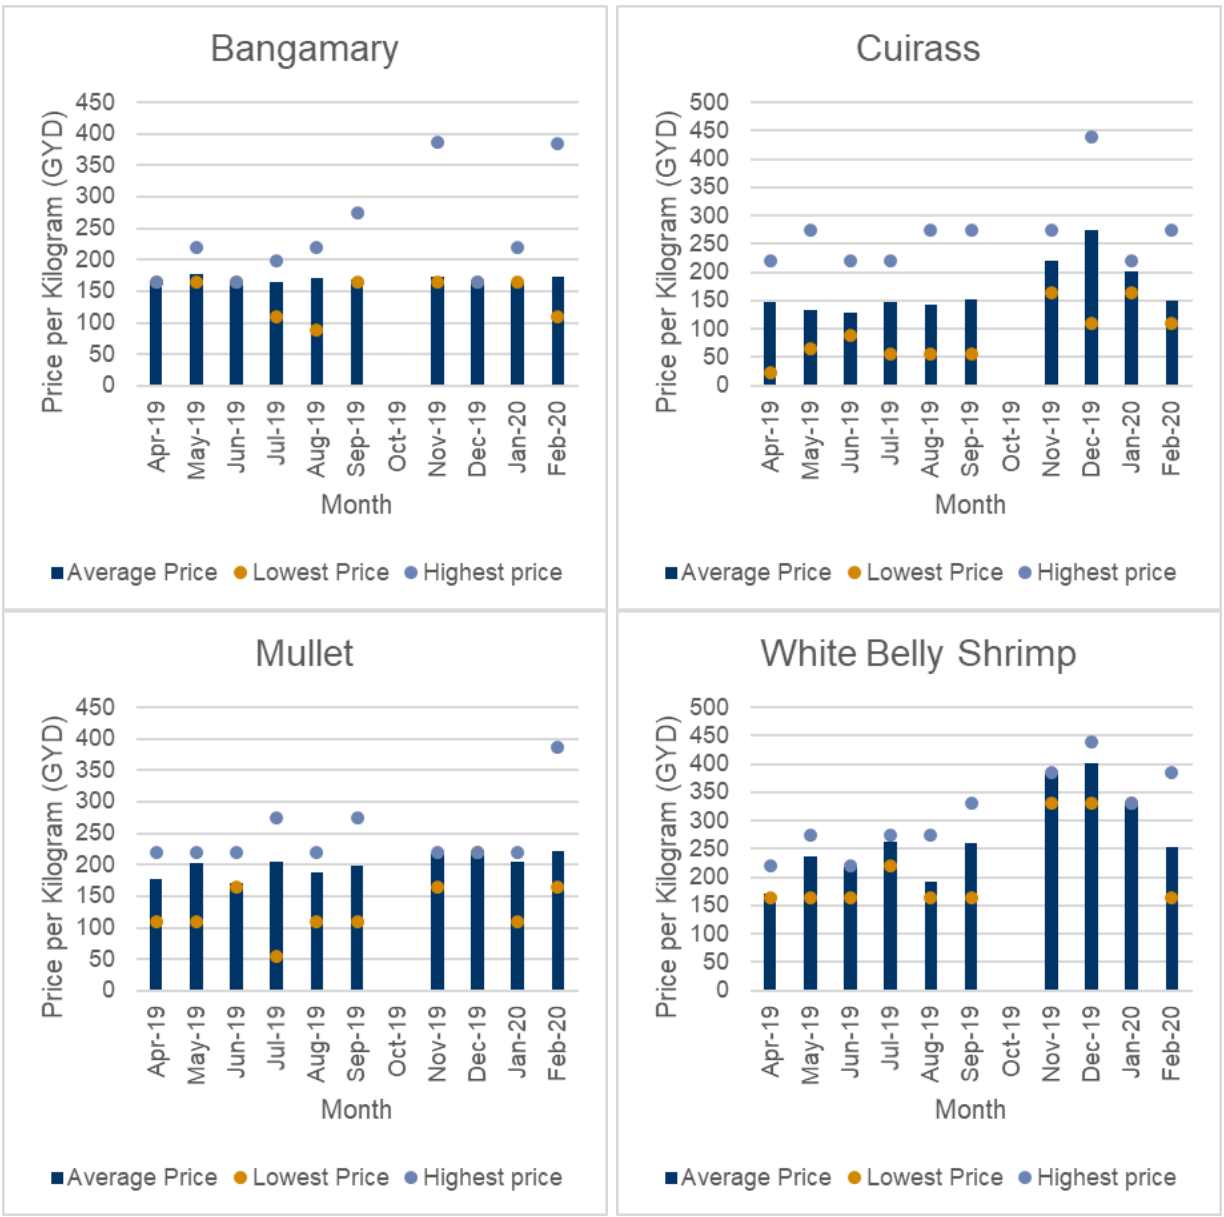

Figure K-7: Monthly Price Variations of the Four Most Abundant Species Caught at Zeeburg Landing Site

2.5 Biometrics

Only limited biometric data were collected by the regional supervisor as the fishes were small and their weights were too low to be accurately measured on the type of scale used for this study (see Figure K-8). Based on the photographs taken by the regional supervisor, and observations of the study team when visiting the landing site, most of the fishes caught were juveniles of their species. Small-bodied species such as mullet, which was the third most abundant species caught, were also abundant. Due to the challenges associated with obtaining accurate weights of small fishes, only larger specimens were weighed, but these were comparatively scarce and not representative of the sizes of fishes normally caught at this landing site. Given the mesh sizes of the Chinese seines used, there are not likely to be any significant differences in the sizes of fishes caught on a seasonal basis. For example, the largest

bangamary recorded was 22.5 centimeters and the largest cuma cuma was 17.5 centimeters, neither of which reached sexual maturity.

3 QA/QC DATA

During the QA/QC exercise in September 2019, one Chinese seine vessel was assessed. The vessel spent 5 hours at sea and soaked the Chinese seine once during that time. The vessel used a 15 hp outboard engine and fished in an area referred to as “Lanka.” These fishing practices are consistent with those reported by the regional supervisor for most of the vessels operating at the landing site.

Several of the commercially viable species reported by the regional supervisor were observed as part of the haul of the vessel assessed. The catch composition of commercially viable species was also consistent with the data collected by the regional supervisor. However, on the day of the visit, market prices were slightly lower than the average prices obtained during the reporting period. In general, most of the commercially viable fish species caught were too small to be weighed (see Figure K-9) or to be differentiated by sex. The regional supervisor recorded no biometric measurements of the fishes because of their small size. However, the study coordinator advised the supervisor to measure lengths of representative samples of landed fishes that are commercially viable and weights, where possible. This will enable greater understanding of the sexual maturity of the fishes caught by the Chinese seine vessels operating at this landing site.

During the QA/QC exercise in January 2020, another Chinese seine vessel was assessed. The vessel took a 12-hour fishing trip and soaked its seines twice. The vessel had a total haul of 50 kilograms (110 pounds), which was lower than the average weight of hauls of 70.5 kilograms (155 pounds) for vessels at this landing site. There was also a change in catch composition, as bangamary accounted for a larger percentage of the haul than white belly shrimp. Fisherfolk interviewed at the landing site indicated that there was a decline in white belly shrimp catch during this period. This contributed to the reduction of overall haul sizes in January 2020 as reported by the regional supervisor.

Prices recorded during the QA/QC exercise reflected those reported by the supervisor, but a variance was observed in the prices of white belly shrimp that was sold for $189 GYD ($0.90 USD) per kilogram during the QA/QC exercise compared to the $330 GYD ($1.60 USD) per kilogram. This was attributed to the fisherfolk trying to sell the relatively small haul quickly. The cuma cuma fish was the most expensive of the haul and this is consistent with the data collected by the regional supervisor.

In addition, the regional supervisor did not record bycatch species that were included as part of the haul. For the vessel assessed during the first QA/QC exercise, there were two species of bycatch namely banjaman and mud eels. Due to the lack of commercial value, fisherfolk at the Zeeburg landing site do not track these species. The study coordinator advised the regional supervisor to commence data collection on bycatch of the hauls in the future. This will enable greater understanding of bycatch from these vessels and also enable comparisons with bycatch reported by onboard supervisors at Windsor Forest (Region 3) and Ogle (Region 4). At the conclusion of the second QA/QC exercise, the study coordinator encouraged the supervisor to collect these data, and also used the opportunity to provide a refresher training on the collection of biometric data. Overall, the study coordinator was satisfied that the onboard supervisor was accurately recording the commercial species caught.

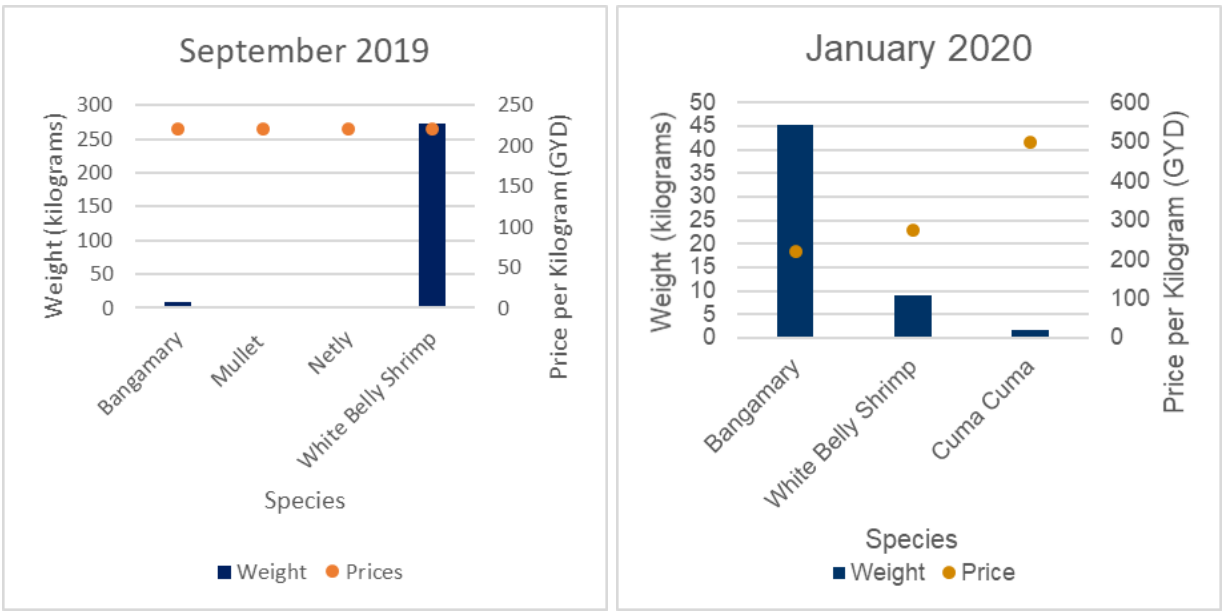

Figure K-8: Total Weight and Prices of Fishes Assessed during the QA/QC Exercises

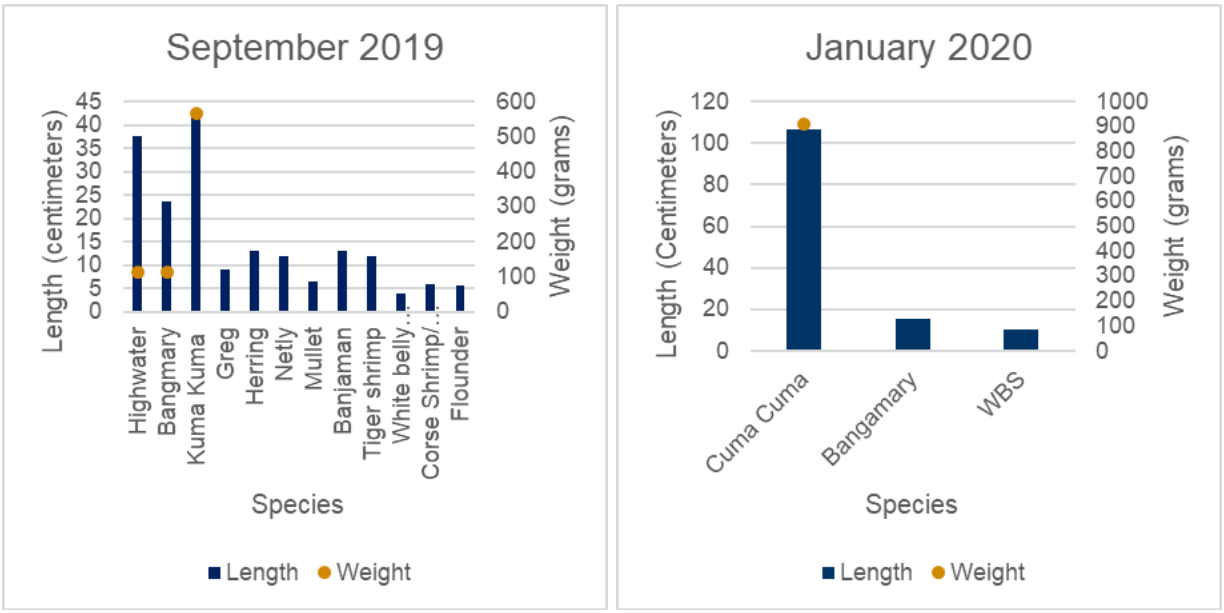

Figure K-9: Lengths and Weights of Species Measured during the QA/QC Exercises

APPENDIX L LA GRANGE (REGION 3)

1 LANDING SITE OVERVIEW

The La Grange landing site is one of the only landing sites in Guyana where almost all fisherfolk still use Cadell lines (demersal longlines) for commercial fishing. The landing site is located on the western bank of the Demerara River. The landing site is farther inland than the other landing sites surveyed, and fisherfolk traverse along the Demerara River to access fishing grounds along the Region 3 and 4 coastlines. Most vessels are outboard cruisers fitted with engines of 15 hp. Fisherfolk using Cadell lines make daily trips lasting from 2 to 16 hours per day. Fisherfolk in La Grange fish about 1 to 25 kilometers offshore at depths of 7 to 27 meters. The main expenses are fuel and fishing bait and each trip costs approximately $20,000 GYD ($96 USD).

Fisherfolk have indicated that the main species caught at this landing site are catfish, cuirass, snapper, trout, and shark. Yield is typically 2 to 4 tubs (1 tub weighs about 25 kilograms, or 50 pounds) of fishes that could be sold for $3,000 to 15,000 GYD ($14 to $72 USD) depending on the species. Fisherfolk also indicated that markets at the landing site and surrounding villages are inconsistent and demand is typically low. As a result, when returning from a fishing trip, most fisherfolk first land their vessels at the Meadowbank Wharf in Region 4 on the eastern bank of the Demerara River, where there are daily active fish markets. Hauls are typically sold to vendors but on occasion, fisherfolk sell directly to consumers. Some fisherfolk also opt to land at the Stabroek Market, also in Region 4 on the eastern bank of the Demerara River, where hauls are sold to vendors.

The main challenges encountered at this site are conflicts with drift seine fisherfolk on occasions when the Cadell lines and drift seines become entangled, and lack of markets. Fisherfolk have also indicated that variable weather patterns, including changes in season, which they state are associated with climate change, may be negatively affecting their activities.

2 ONBOARD SUPERVISOR RESULTS

The onboard supervisor at this site uses Cadell lines to fish. Each fishing trip lasts 10 to 12 hours. On each fishing trip, approximately 500 Cadell lines are soaked for approximately 1 hour. Lines are soaked once or twice per fishing trip. The onboard supervisor travels farther offshore than any of the other onboard supervisors with fishing grounds located approximately 40 kilometers (23.9 miles) offshore. The vessel is an outboard cruiser fitted with a 15 hp engine. Travel time to the fishing grounds is approximately 4 hours. On commuting to the fishing grounds, the onboard supervisor typically meets with fisherfolk who use Chinese seines and drift seines around the mouth of the Demerara River. The onboard supervisor purchases small fishes and shrimp from these fisherfolk to be used as bait attached to the Cadell lines and has indicated that this is a common practice for Cadell fisherfolk. On the return trip, the supervisor typically lands first at the Meadowbank Wharf to sell the haul to vendors. The vessel is staffed with a four-member crew inclusive of the onboard supervisor. The onboard supervisor did not report any significant challenges that affected his fishing activities over the study period.

2.1 Target Species and Diversity

The total weights of combined hauls from the onboard supervisor's vessel over the April 2019 to February 2020 period was of 30,656 kilograms (67,585 pounds) from 1,367 hours of effort. As seen on Figure L-1, sea catfish was by far the most abundant species caught accounting for 85 percent of the total haul with 26,271 kilograms (57,918 pounds). This is similar to the haul of the onboard supervisor from Waramuri (Region 1) where sea catfish comprised 75 percent of the haul from Cadell lines. Hauls from fishing activities using Cadell lines targets species that are benthic feeders because the hooks attached to the lines lie on the seafloor. Cuirass, kokwari, and snapper were the second, third, and fourth most abundant

species caught with total weights of 2,099 kilograms (4,627 pounds), 1,126 kilograms (2,482 pounds), and 606 kilograms (1,336 pounds), respectively.

A total of 13 species were recorded by the onboard supervisor although nine were caught in relatively low quantities of lower than 500 kilograms (1,100 pounds). This is higher than the species diversity reported by the onboard supervisor at Waramuri where only five species were caught but lower than the species diversity of different seine types, in particular from seines with small mesh sizes. The eel caught is not sold as a commercial species, but is used by the onboard supervisor as bait. The difference in species diversity from La Grange to Waramuri could be attributed to the fishing grounds, relative distances at which fishing occurs from the shore, and the dynamics of different river systems. No bycatch was recorded by the onboard supervisor. Generally, there is little to no bycatch from this type of fishing.

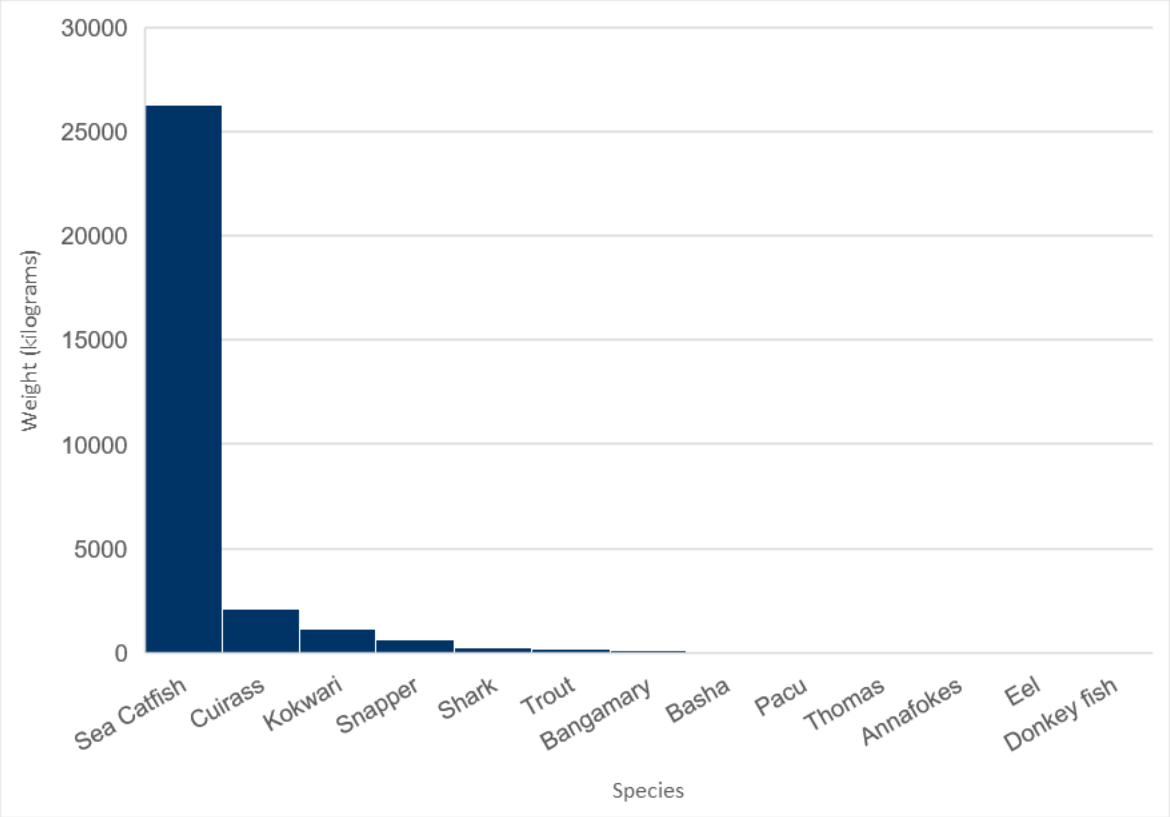

Figure L-1: Total Weight of Species Recorded by the Onboard Supervisor at the La Grange Landing Site

2.2 Fishing Area

The onboard supervisor's fishing points were clustered in a main fishing area, which covered 266 square kilometers (see Figure L-2). The onboard supervisor traveled 36 kilometers to access these fishing grounds from the landing site and 31 kilometers from the mouth of the Demerara River. In total, the onboard supervisor had a traveling range of 2,226 square kilometers which is farthest offshore of any of the onboard supervisors in the study.

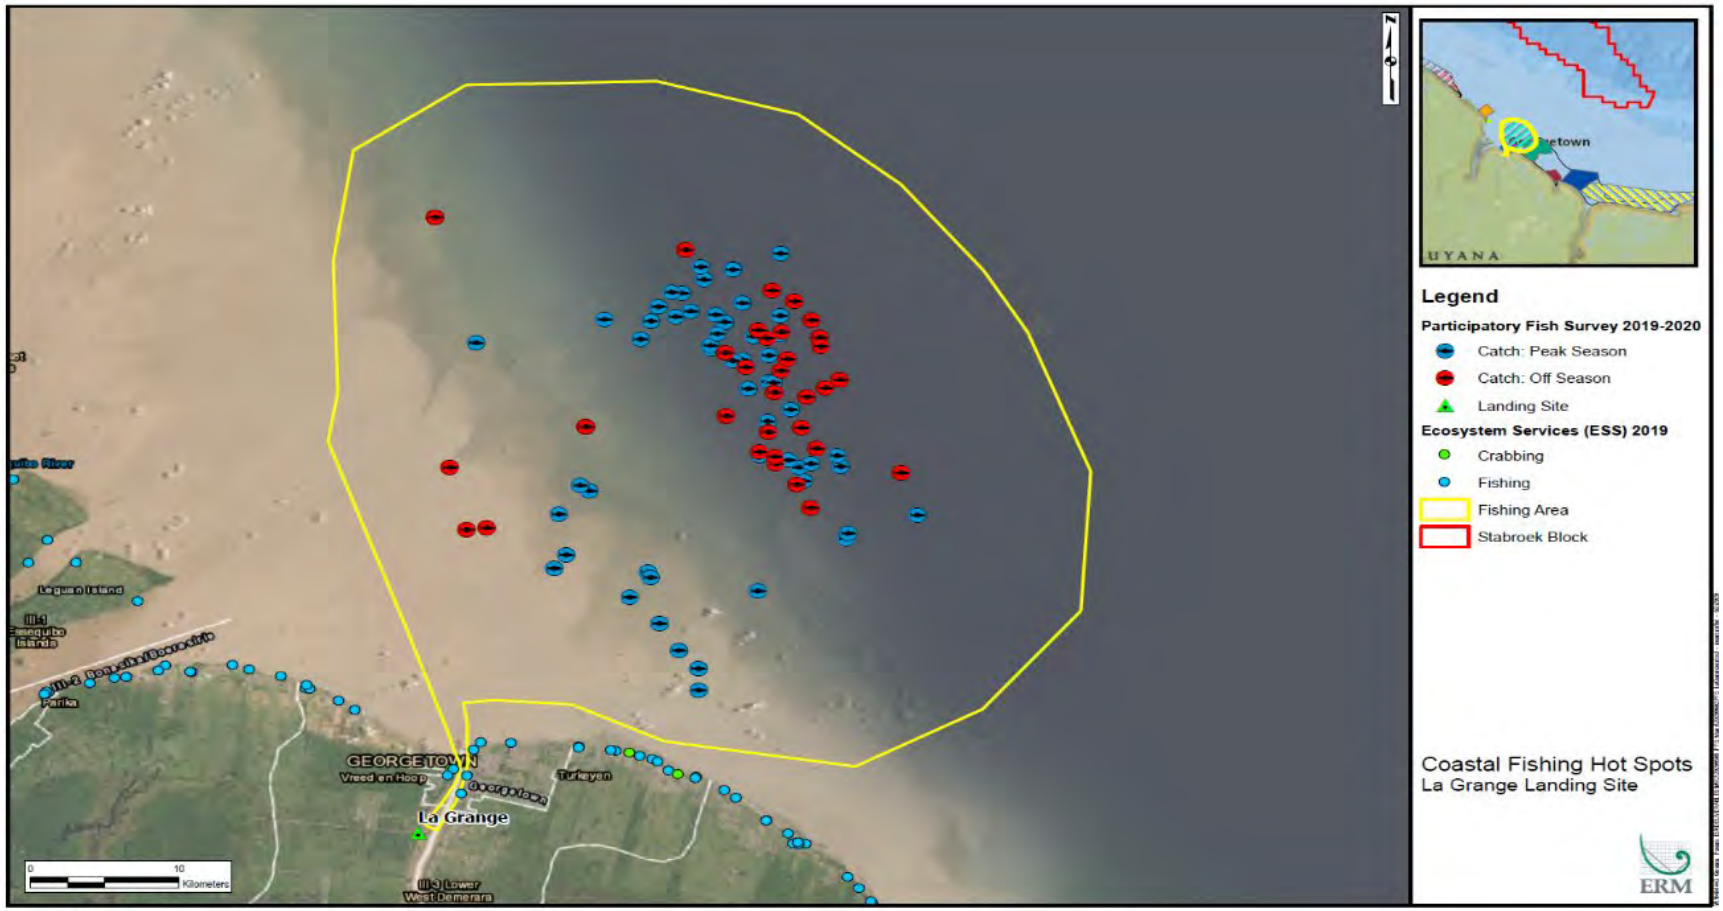

Figure L-2: Fishing Area and Fishing Points Used by the La Grange Onboard Supervisor

The onboard supervisor used fishing points closest (9.3 kilometers) and farthest (46.5 kilometers) from the shoreline during the good season. As a result, there are no clear seasonal trends on the distance at which fishing points were located throughout the study period. In addition, the most eastward fishing points were observed during the good season. The currents in fishing grounds move westward and as a consequence, it is likely that the supervisor traveled farther east against the currents during the good season when fisherfolk reported that waters are calmer and more conducive to fishing.

2.3 Seasonal Productivity

The onboard supervisor subscribes to the commonly-held view that fishing is most productive from May to September (the so-called “good season” that peaks in July to September) and less productive from October to March (the so-called “hard season”). It is widely believed that waters are warmer and calmer during the good season, and these conditions are more conducive to fishing. These seasons are believed to influence effort expended by fisherfolk as well as hauls per soaking of the seine and per fishing trip.

During the study period, the onboard supervisor spent an average at 124 hours per month fishing, but the effort expended per fishing trip varied on a monthly basis as seen on Figure L-3. For example, the highest effort was expended in October 2019 when 228 hours were spent fishing. By contrast, the lowest effort was expended in January 2020 when only 24 hours were spent fishing. Based on the onboard supervisor’s fishing practices, monthly effort of 228 hours suggests that there were at least 22 fishing trips in October 2019 while monthly effort of 24 hours suggests that there were only two fishing trips in January 2020. Figure L-4 and Figure L-5 show the total weight of hauls on a monthly basis and the average haul weight per soaking of the seine. In May and July 2019, the highest total hauls and average hauls per soaking were observed. The November 2019 to February 2020 period saw consistently low hauls.

Seasonal variations in effort and productivity were observed as follows:

- In the May to September 2019 good season, the total weight of hauls was 22,146 kilograms (48,824 pounds) with 611 hours spent at sea. On average, a soaking during this period yielded 455 kilograms (1,003 pounds). Total haul and average weight of hauls per soaking peaked in July 2019. In addition, May 2019 was the second most productive month. In both months, effort expended was in the medium range for this landing site with 116 hours in May and 119 hours in July. However, in August 2019, the monthly effort and total haul were the lowest of the good season and were comparable to levels observed during the hard season. The reason for this decline is unknown.

- In April 2019 and during the October 2019 to February 2020 hard season, the total weight of hauls was 8,805 kilograms (19,411 pounds) with 757 hours spent at sea. On average, a soaking in this period yielded 130 kilograms (287 pounds). Although the onboard supervisor expended the greatest effort in October 2019, total hauls and average weight of hauls per soaking declined compared to September. From November 2019, the effort and total haul consistently declined and reached the lowest levels in January 2020. In addition, average hauls per soaking were consistently low for most of the hard season in April 2019 and during the November 2019 to February 2020 period.

By comparison, seasonal trends in the wet and dry season were as follows:

- In August to October 2019, the primary dry season, the total weight of hauls was 7,864 kilograms (17,337 pounds) with 432 hours spent at sea. On average, a soaking during this period yielded 225 kilograms (496 pounds).

- In May to July 2019, the primary wet season, the total weight of hauls was 18,524 kilograms (40,838 pounds) with 407 hours spent at sea. On average, a soaking during this period yielded 608 kilograms (1,340 pounds).

- In February 2020 and April 2019, 2 months of the secondary dry season, the total weight of hauls was 2,320 kilograms (5,115 pounds) with 276 hours spent at sea. On average, a soaking in this period yielded 144 kilograms (317 pounds).
- In November 2019 to January 2020, the secondary wet season, the total weight of hauls was 3,513 kilograms (7,745 pounds) with 408 hours spent at sea. On average, a soaking during this period yielded 111 kilograms (245 pounds).

Based on the trends discussed above, the productivity of fishing activities was seasonal and adhered to the periods for the good and hard seasons. Average hauls per soakings were also greater during the good season as compared to the hard season. Climatic seasonality did not influence productivity. This also translated to greater productivity in the primary wet and dry seasons compared to the secondary wet and dry season. The trends also demonstrated that the relationship between effort expended and total haul is also ultimately determined by the seasons. In particular, greater effort is not a guarantee of greater productivity. Several factors influenced the onboard supervisor's decision to reduce fishing activity in January 2020. The onboard supervisor explained that low effort was expended due to the rough seas during the hard season and a decision to spend some time relaxing with family.

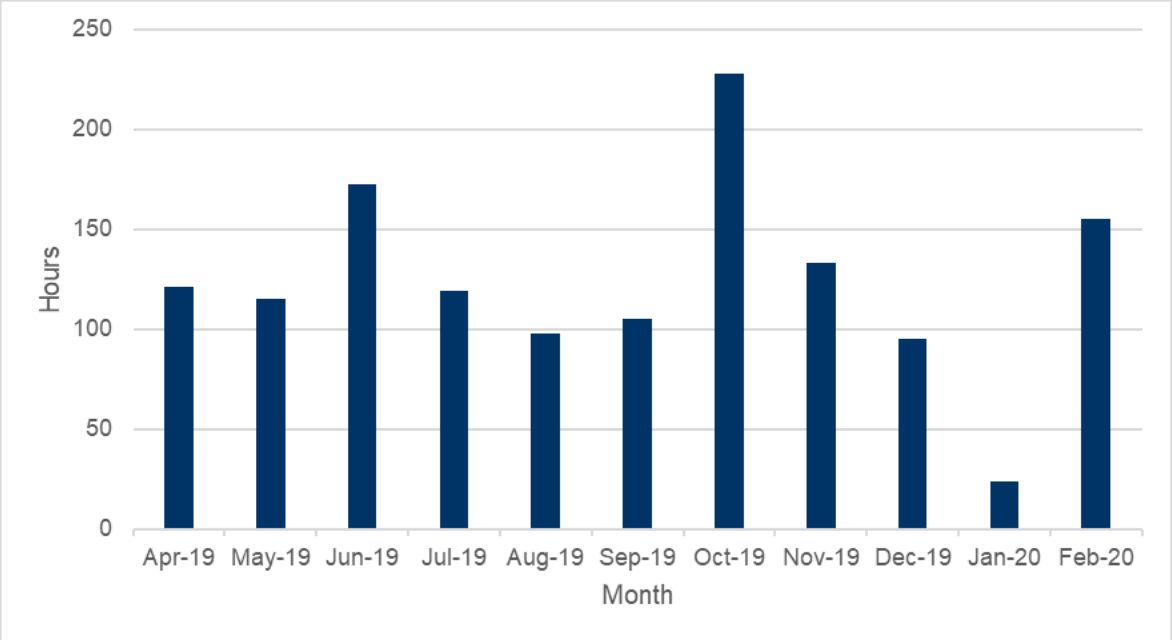

Figure L-3: Total Monthly Fishing Effort Recorded by the La Grange Onboard Supervisor

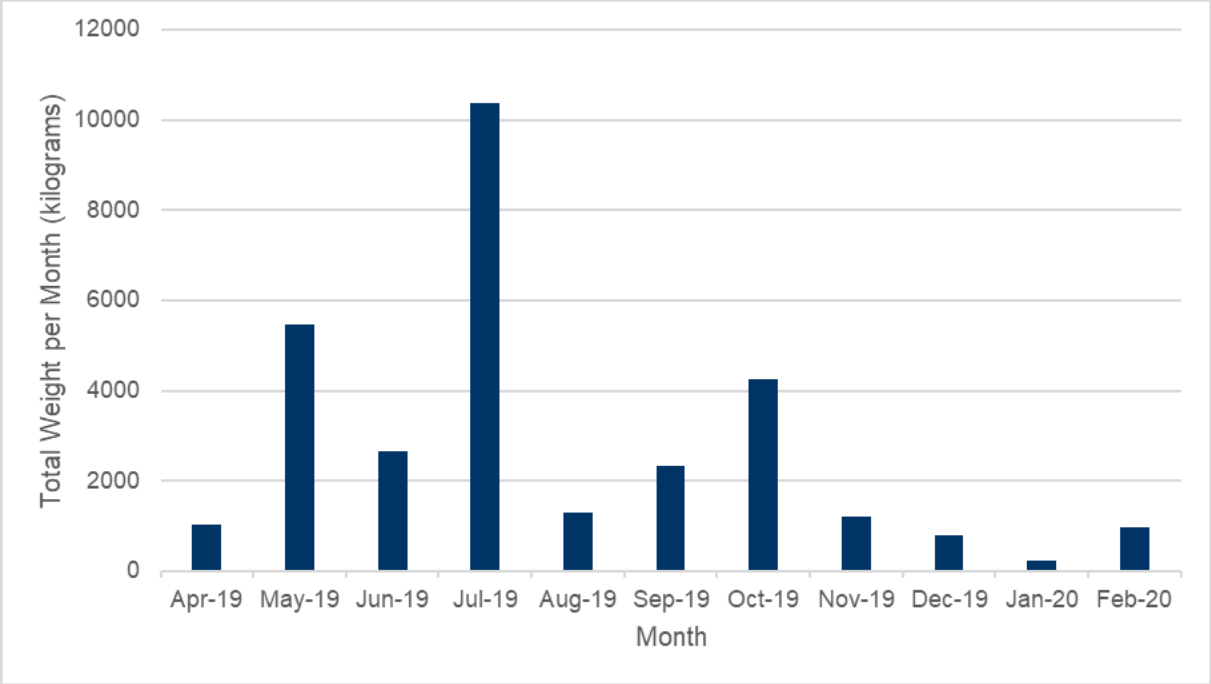

Figure L-4: Total Weight of Species Recorded by the La Grange Landing Site

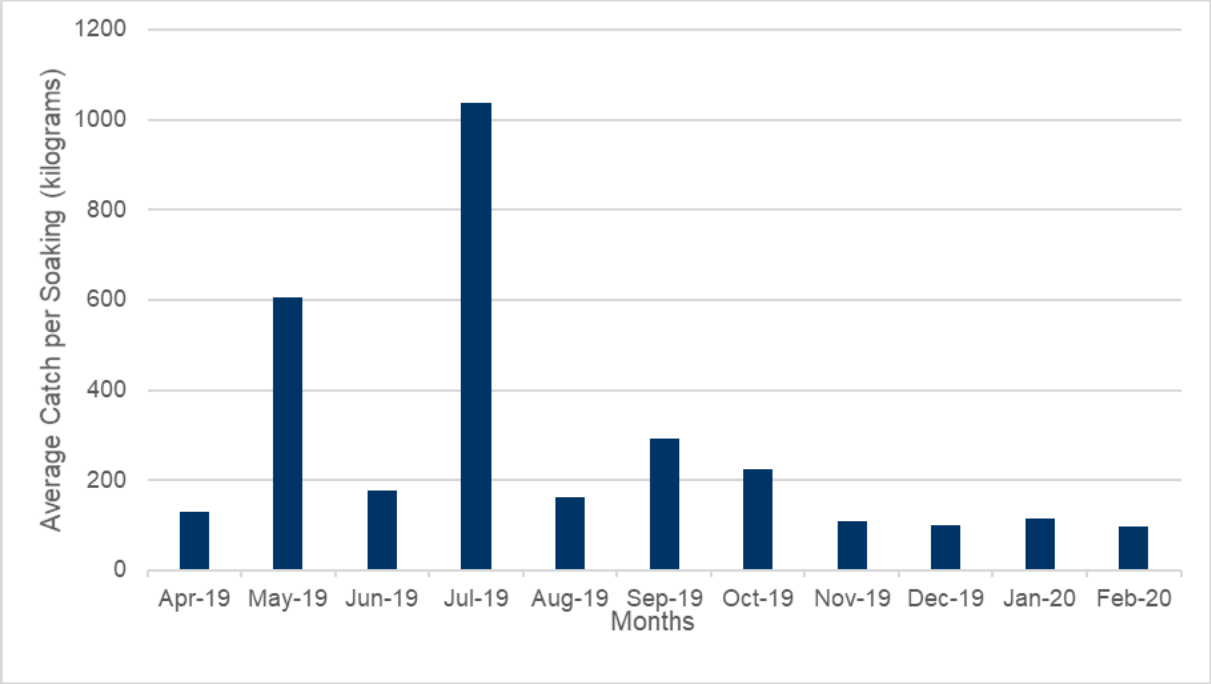

Figure L-5: Average Weight per Soakings Recorded by the La Grange Landing Site

2.4 Biometrics

The onboard supervisor measured the lengths and weights of representative fishes per haul and the annual average lengths and weights of these fishes are shown on Figure L-6. Based on the

measurements taken by the onboard supervisor, most of the fishes caught were sexually mature. It should be noted that the annual average lengths of basha and bangamary indicate that they were relatively small for their species, but had achieved mature sizes. Basha are considered sexually mature at a length of 25 centimeters, and the annual average length of the fishes caught was 28 centimeters. Bangamary are considered sexually mature at a length of 24 centimeters, and the annual average length of the fishes caught was 27 centimeters.

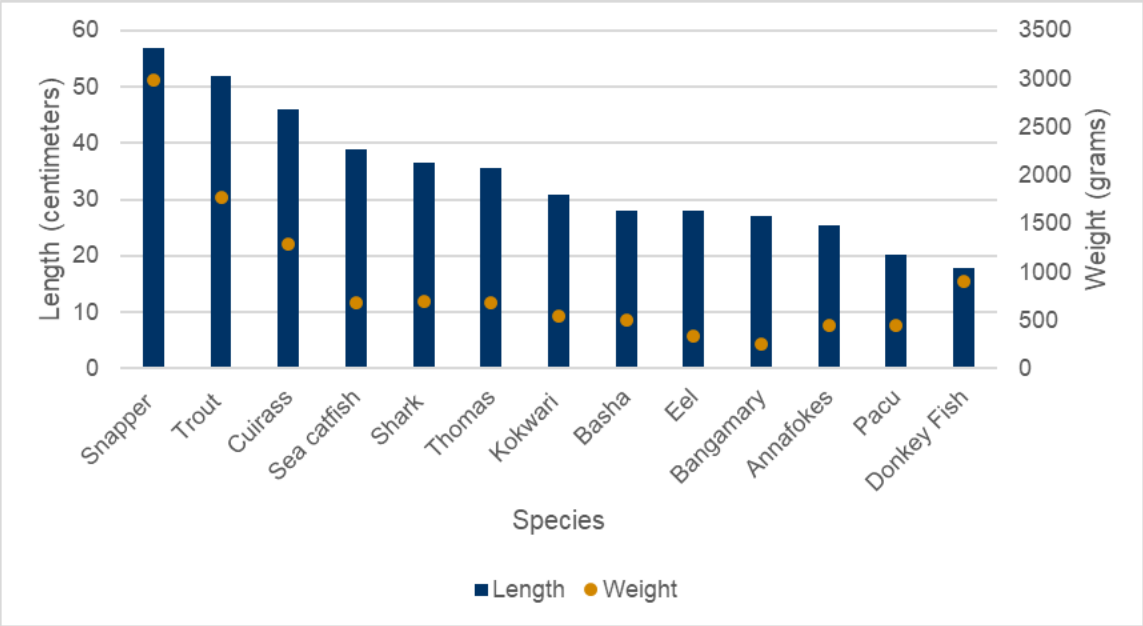

Figure L-6: Average Length and Weight of Fishes Caught by the La Grange Onboard Supervisor

The monthly average lengths and weights of the four most abundant species caught are presented on Figure L-7. Sea catfish, the most abundant species caught, representing 85 percent of the total haul, were largest in the May to September 2019 good season. The largest sea catfishes were caught in September 2019 and these fishes were likely spawning females. The July to September period is widely believed to be the spawning period and females caught are frequently carrying eggs, which contributes to larger fishes being caught at this time of the year. The onboard supervisor could not confirm whether larger fishes caught over the July to September spawning period were spawning females, as fish are not gutted prior to sale. When the spawning period ended, smaller fish were caught. In fact, the fish caught from October 2019 to February 2020 were consistently smaller than those caught between May and September 2019. Sea catfish caught in October, November, and December were below average lengths for this species.

Although snapper, cuirass, and kokwari were among the most abundant species caught in the total haul, they were not caught in every month (Figure L-7). Larger individuals of snapper and cuirass were caught in April to June 2019 and both species were at peak weights in April. By comparison, kokwari achieved peak weights in October. Given that the supervisor does not gut fishes prior to sale, it is not clear whether these larger fishes were spawning females. In addition, snapper caught in February 2020 were considered juveniles and cuirass caught in October, November, and December were below average lengths. None of the kokwari caught were considered juvenile.

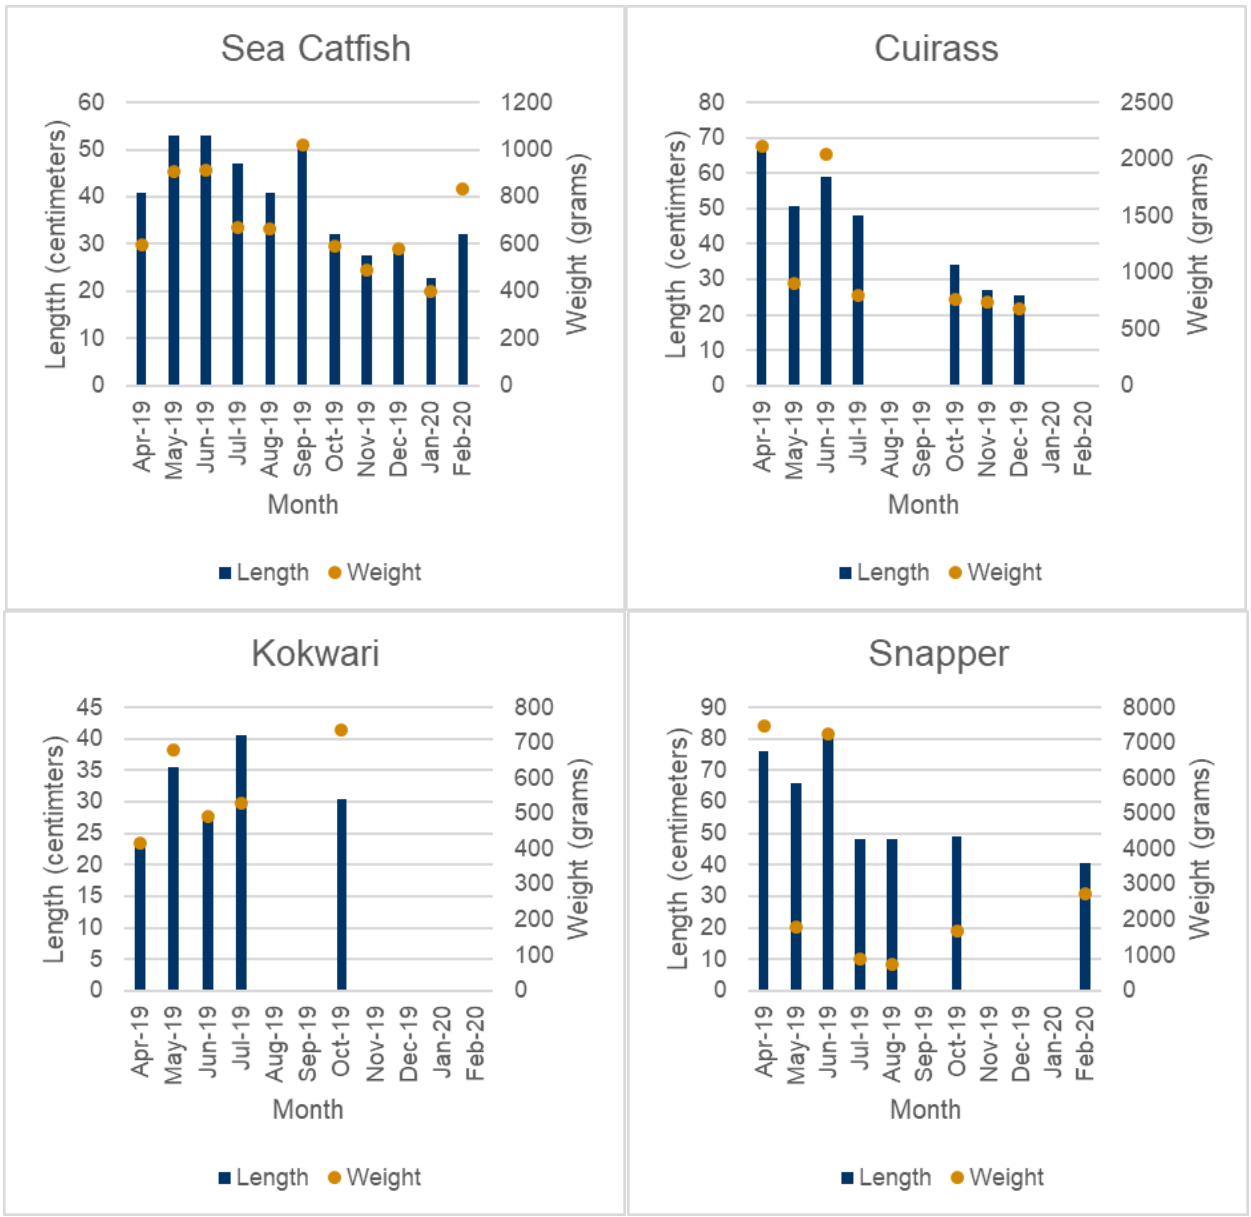

Figure L-7: Monthly Average Length and Weight of Most Caught Species at the La Grange Landing Site

3 QA/QC DATA

As part of the QA/QC exercise, a GoPro camera was mounted to the onboard supervisor's vessel (Figure L-8). Several key observations were made from the video monitoring that was conducted over the period of 24 to 26 September 2019.

- The onboard supervisor met with a Chinese seine fisherman at the mouth of the Demerara River to purchase bait to be attached to the Cadell lines. Subsequent discussions with the onboard supervisor revealed that purchasing bait from Chinese seine fisherfolk is a common practice by fisherfolk who use Cadell lines for fishing.

- The supervisor took 6 hours to travel from the La Grange landing site to the fishing ground used on the day of the observation. This included a 2-hour period that was used to collect bait from Chinese seine fisherfolk at the mouth of the Demerara River.
- The Cadell lines were then soaked for 1 hour before being picked up by the crew members.
- The supervisor was the navigator for the entire fishing trip. Two crew members pulled up the lines while one member sorted the catch.
- The supervisor sold the fishes caught at the Meadow Bank Wharf, which can be accessed along the Demerara River while the vessel was en route back to the La Grange landing site.

The haul could not be assessed by the study team because the onboard supervisor had sold it at the Meadow Bank Wharf before returning to the landing site. However, the supervisor kept three fishes on which the study coordinator could conduct biometric assessments. As seen on Figure L-9, the fishes were similar in size to those for which biometric data were collected by the onboard supervisor during the reporting period. Overall, the study team was satisfied that the onboard supervisor was accurately recording the commercial species caught and following the guidance provided in taking biometric measurements.

Based on the data collected by the onboard supervisor for this trip, species composition for this haul was the same as reported during this trip. In addition, sea catfish comprised the largest percentage of the total haul, consistent with trends observed at this landing site during the study period.

During the second QA/QC exercise, the team was unable to collect data from the onboard supervisor's vessel because the onboard supervisor was on vacation and fishing activities by other fisherfolk at the landing site were limited.

Figure L-8: GoPro Being Mounted during QA/QC

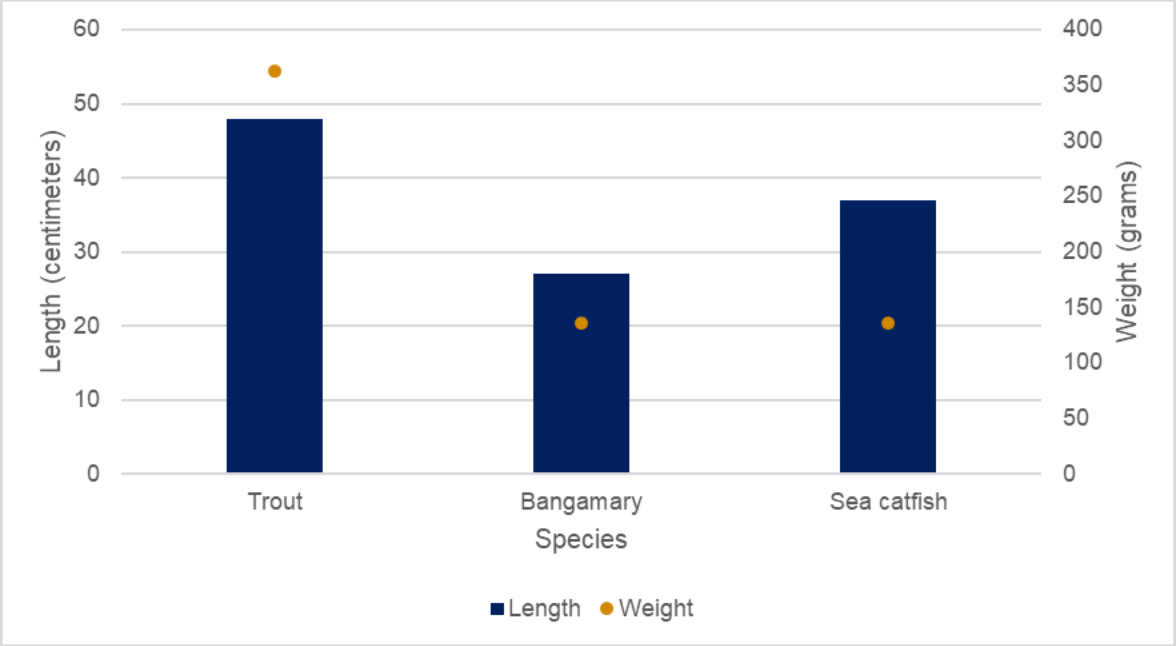

Figure L-9: Biometric Measurements Verified at the La Grange Onboard Supervisor

APPENDIX M WINDSOR FOREST (REGION 3)

1 LANDING SITE OVERVIEW

Windsor Forest is a medium-sized landing site on the west coast of Demerara in Region 3. Approximately 12 vessels use this landing site, all of which use Chinese seines with mesh sizes ranging from 2.5 to 10 centimeters (1 to 4 inches). Some of the fisherfolk use the Cadell method of fishing to augment the Chinese seines. All vessels are outboard cruisers equipped with engines of 15 to 40 horsepower (hp). Fisherfolk make daily trips to the Chinese seine "pens" located approximately 10 kilometers offshore. Fishing trips for Chinese seine vessels are dependent on the tides and a trip typically last for approximately 6 hours. The main expenditure for fishing trips is fuel since ice is not required for preservation of the haul. An average fishing trip costs $1,500 GYD ($7.20 USD).

A basket of "mixed fishes," typically comprised of bangamary, netly, Suriname mullet, and small herrings, is sold for approximately $120 GYD ($0.6 USD) per kilogram (depending upon season) to vendors who visit the landing site. Some vendors have refrigerated trucks, although this practice is not as prevalent at this landing site. Most of the haul is sold at the local marketplace.

The main challenge encountered by fisherfolk at this landing site is conflict with anchor seine vessels and sargassum.

2 ONBOARD SUPERVISOR RESULTS

The onboard supervisor at the Windsor Forest landing site uses Chinese seines with mesh sizes of 2.5 to 10 centimeters (1 to 4 inches). The primary target species is white belly shrimp, and this is caught mainly with seines that have mesh sizes of 2.5 to 10 centimeters (1 to 4 inches). However, the supervisor uses Chinese seines with larger mesh sizes to catch fishes because hauls of white belly shrimp are variable and the good season is not long enough to make shrimping an economically viable livelihood activity. Fishing trips are tidal and the onboard supervisor used the high tide to travel to the pens to set the seine. The onboard supervisor has five pens located approximately 20 kilometers from the shore.

The supervisor also uses Cadell lines year-round. On a fishing trip, Cadell lines are soaked en route to the Chinese seine pens. This is similar to the onboard supervisor from the Lima landing site (Region 2) who uses other methods of fishing to augment Chinese seines with mesh sizes of 2.5 to 10 centimeters (1 to 4 inches). Each fishing trips lasts 7 to 8 hours, on average. The onboard supervisor's vessel has an estimated haul capacity of 500 kilograms (1,100 pounds). In general, the supervisor returns to the landing site after the seine has been hauled. The vessel has a two-member crew and is powered by a 15 hp engine. The main expense for fishing activities is fuel as there is no need for ice. The main challenge faced by the onboard supervisor was the proliferation of sargassum during the February to May period, which became entangled in the seines and constituted significant portions of the total haul.

2.1 Target Species and Diversity

The total weight of combined hauls during the data collection period was 40,727 kilograms (89,787 pounds). Although the primary target species was white belly shrimp, it was not the most abundant species caught. This is significantly different from hauls recorded by the onboard supervisor at the Lima landing site (Region 2) and the Zeeburg landing site (Region 3) where Chinese seines were also identified as the main fishing method and white belly shrimp was the most abundant species caught. Instead, as seen on Figure M-1, bangamary was the most abundant species caught, with a total weight of 9,817 kilograms (21,642 pounds), representing 24 percent of the total haul. Sea catfish and small banga were the second and third most abundant species caught, representing 14 and 11 percent of the total haul, respectively. The onboard supervisor disaggregates bangamary in the haul based on size. A reference to "bangamary" is to the larger fishes of this species that have, in general, reached sexual

maturity. “Small banga” is an umbrella term for a mixture of several species of small fishes that are typically juveniles, including bangamary, pilot fish, and herring among others. White belly shrimp, the primary target species, was the fourth most abundant species caught, with a total weight of 4,438 kilograms (9,784 pounds), representing 11 percent of the total haul.

Overall, the onboard supervisor recorded more than 12 different species of fish and shrimp (small banga represents at least three different species of fishes). The catch composition is reflective of the varied type of gear used throughout the year. For example, white belly shrimp are the target species of Chinese seines, sea catfish are the target species of Cadell lines, and bangamary, gillbacker, and trout are the target species of seines with a range of mesh sizes. Bycatch also accounted for a significant portion of the hauls, although weights were not recorded. Bycatch typically consisted of sargassum, jellyfishes, and rockhead fish.

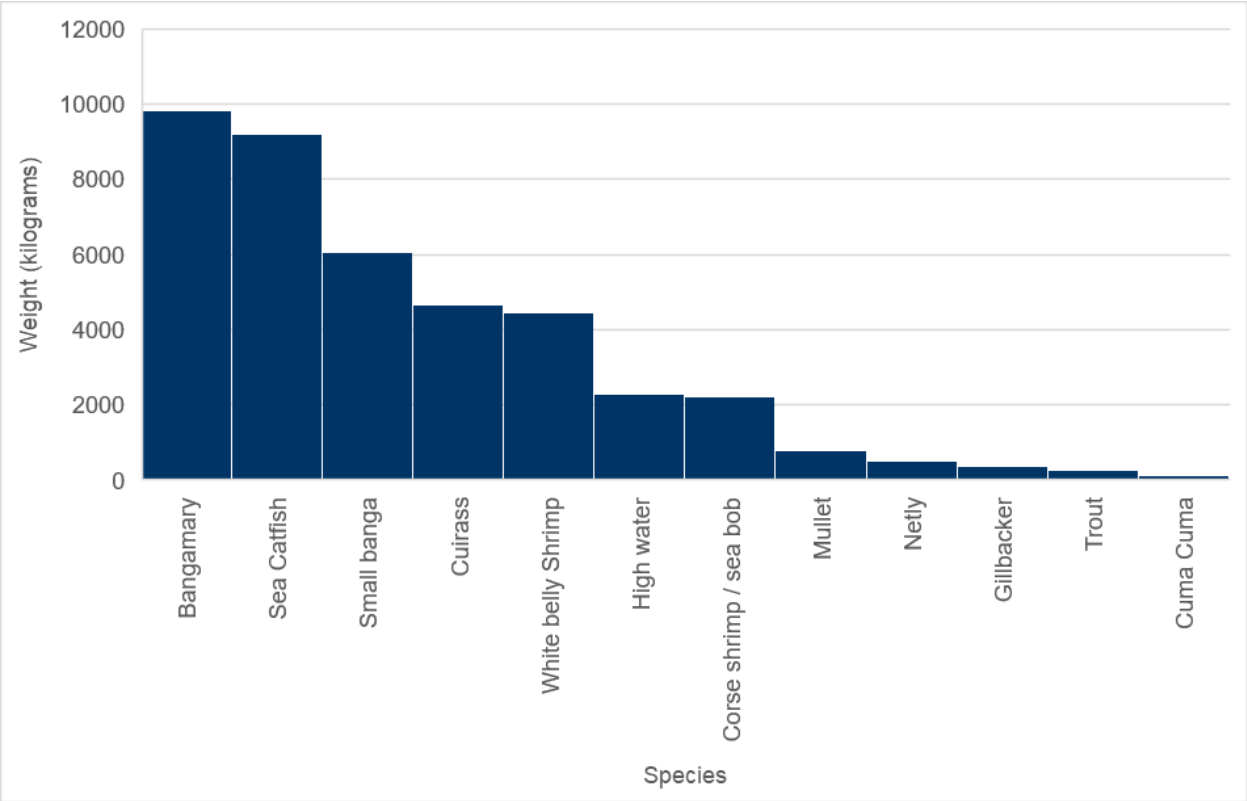

Figure M-1: Total Weight of Species Recorded by the Onboard Supervisor at the Windsor Forest Landing Site

2.2 Fishing Areas

The onboard supervisor uses a fishing area of 25 square kilometers (see Figure M-2). The fishing points used by the supervisor marks the locations of the Chinese seine pens that are used alternately by the onboard supervisor. The pens are located approximately 10.3 kilometers offshore. This is significantly farther than the pen used by the onboard supervisor at Lima to set Chinese seines. During the study period, the onboard supervisor also used Cadell lines for commercial fishing, but the locations at which these lines were soaked were not marked by the supervisor.

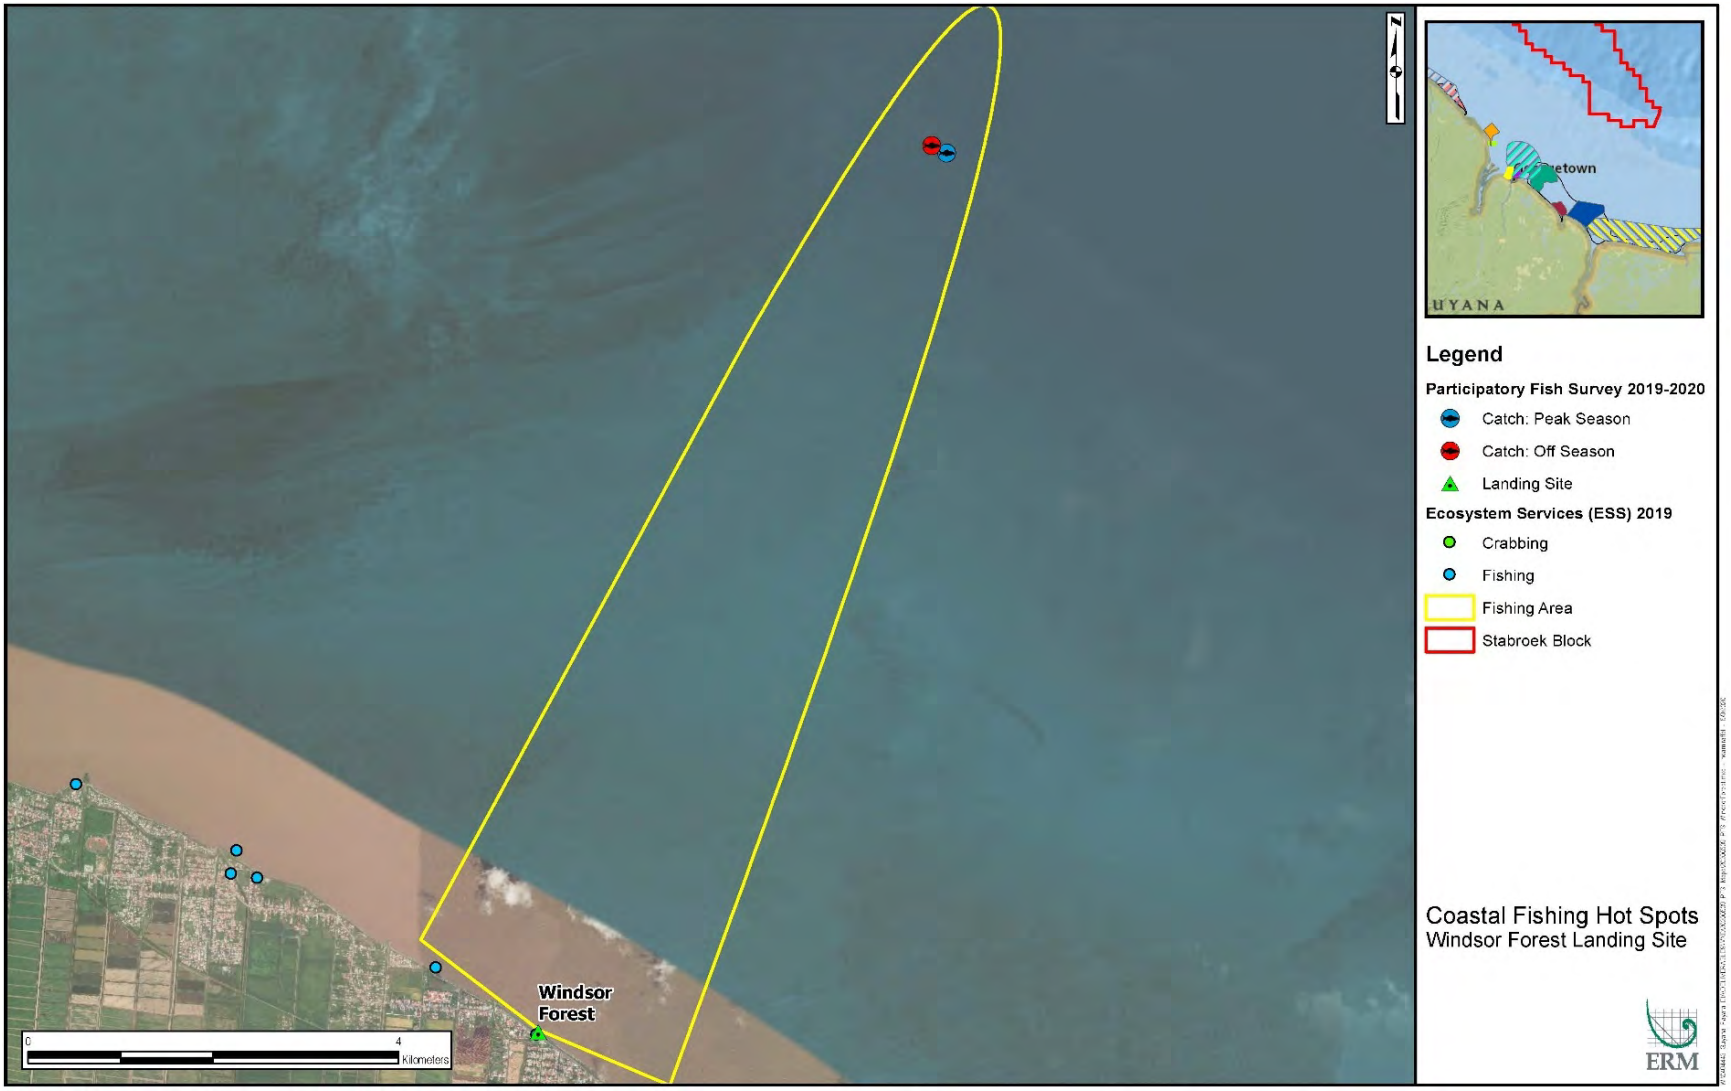

Figure M-2: Fishing Area and Fishing Points Used by the Windsor Forest Onboard Supervisor

2.3 Seasonal Productivity

Fisherfolk contend that the May to September period is the “good” season that peaks from July to September, and that October to March is the “hard” season. It is widely believed that waters are warmer and calmer during the good season, and that these conditions are more conducive to fishing. However, fisherfolk have varying beliefs on the most productive months for shrimping. At the Zeeburg landing site (Region 3), some fisherfolk indicated that shrimp catch generally increases during the closed trawl season, which occurs from 16 August to 5 October annually, and may allow more shrimp to come closer to the shore. Other fisherfolk indicate that the average productivity increases during the dry seasons of February to April and August to September because the waters are generally more saline compared to the wet season. Another common belief is that shrimp productivity increases during the spawning seasons of January to April and June to July (Pereira et al. 2017) when shrimp come closer to shore to spawn in the mangroves. Due to the varied fishing methods practiced by the onboard supervisor, it is unlikely that there are clear seasonal trends in either effort or hauls. This was also observed in the hauls from the onboard supervisor at the Lima landing site (Region 2) where drift seines, pin seines, and Cadell lines augment Chinese seine fishing.

The onboard supervisor spent an average of 129 hours at sea per month as seen on Figure M-3. The greatest effort was expended in November 2019 and February 2020, with 181 and 168.5 hours, respectively. By contrast, the least effort was expended in December 2019 when 109 hours were spent fishing. This is similar to the fishing practices of the onboard supervisor at the Lima landing site (Region 2) where the greatest effort was also expended in November 2019 and January 2020 and the least effort in December 2019. Although 40 hours were expended in April 2019, data collection did not begin until 16 April 2019, and as such, the monthly data pool may not be comparable.

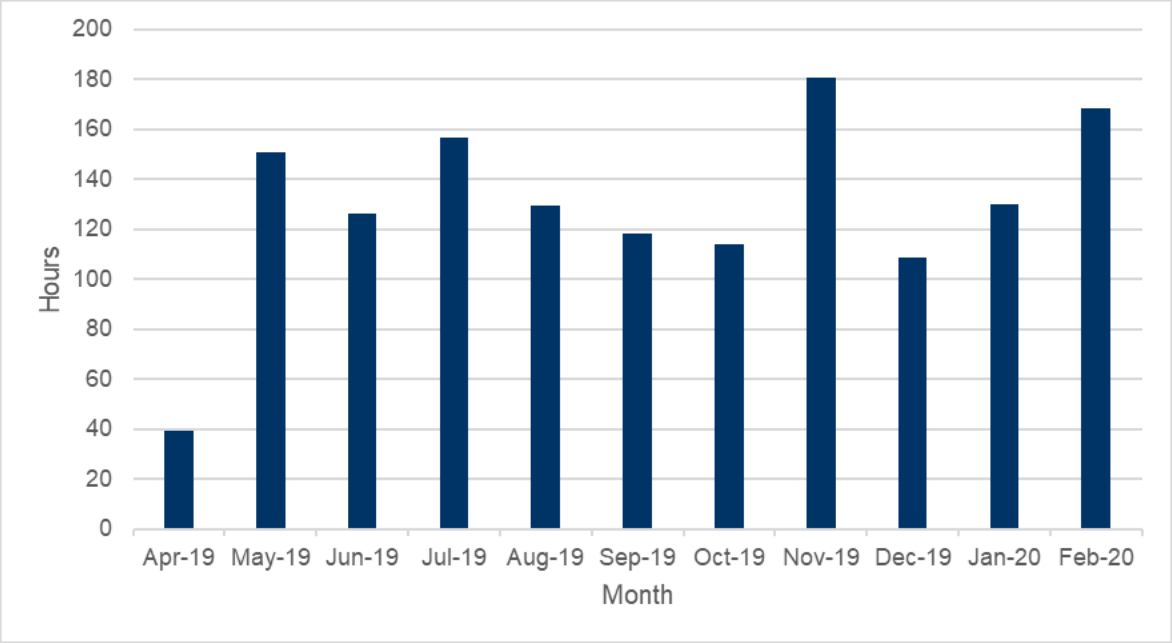

Figure M-3: Total Monthly Fishing Effort Recorded by the Windsor Forest Onboard Supervisor

As seen on Figure M-4, the highest average catch per soaking and greatest total haul were recorded in May 2019, with 13,678 kilograms (30,154 pounds) and 595 kilograms (1,312 pounds), respectively. The

second most productive month was July 2019 when average catch per soaking was 519 kilograms (1,144 pounds) and total haul was 10,373 kilograms (22,868 pounds). Low hauls were consistently recorded from August 2019 to February 2020, although effort in November 2019 and February 2020 were the highest levels of effort expended. Hauls in May and July 2019 were up to five times greater than the other months. The lowest total haul was seen in April 2019, but as previously noted, the data pool for this month was smaller and is not comparable. The lowest total haul of white belly shrimp was recorded in January 2020 with 181 kilograms (399 pounds), while the greatest total haul was in May 2019 with 2,556 kilograms (5,635 pounds).

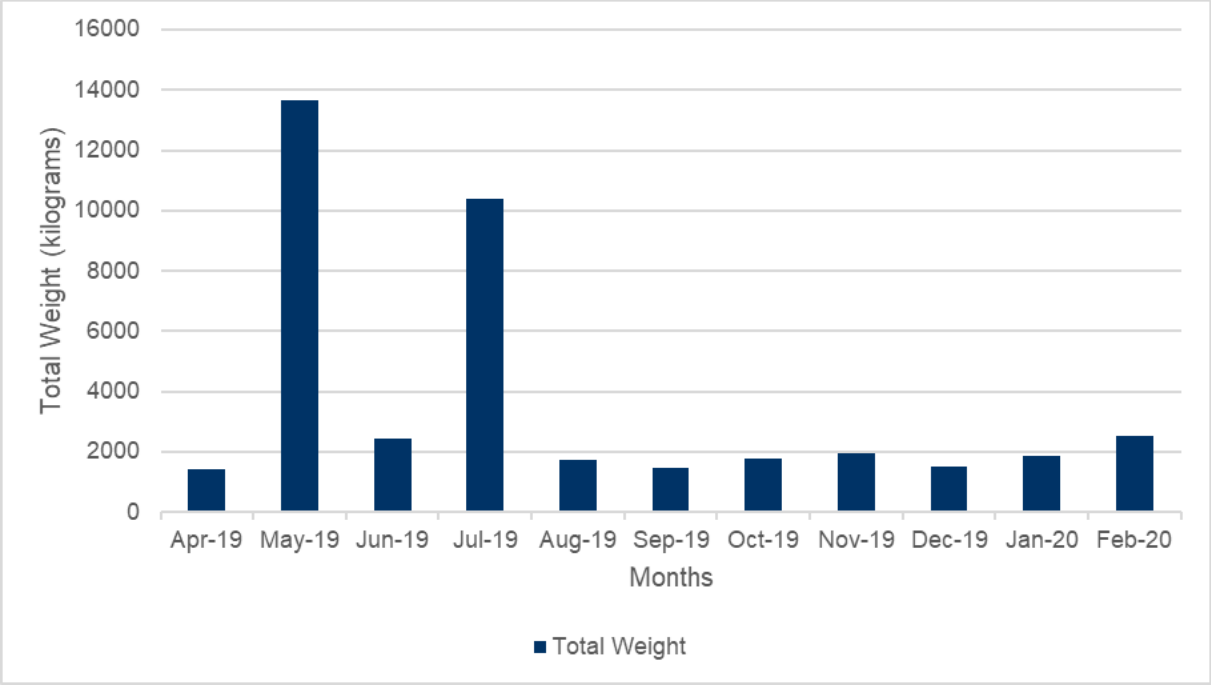

Figure M-4: Total Weight of Species Recorded by the Windsor Forest Onboard Supervisor

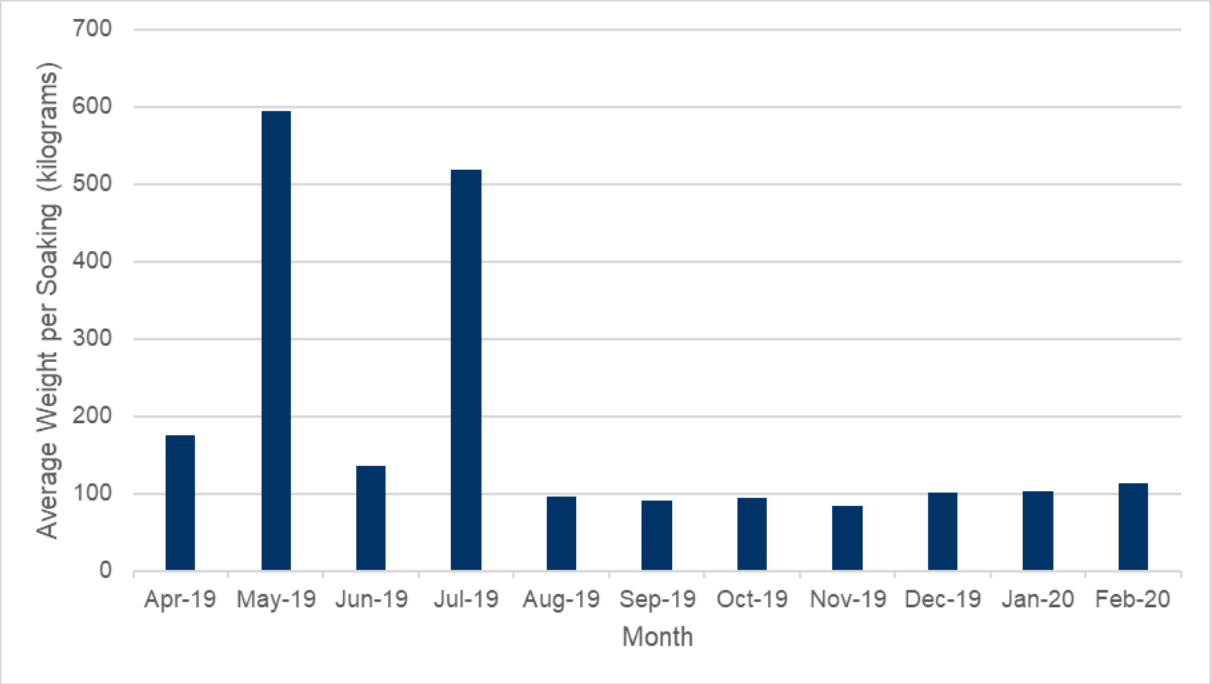

Figure M-5: Average Weight per Soaking Recorded by the Windsor Forest Onboard Supervisor

Seasonal comparisons of effort expended by the onboard supervisor and the hauls recorded are as follows:

- In the May to September 2019 good season, the total weight was 29,682 kilograms (65,438 pounds), with 683 hours spent at sea. On average, soaking of the seine during this period yielded 287 kilograms (633 pounds). In addition, the two most productive months, May and July, were part of this season.
- In April 2019 and the October 2019 to February 2020 hard season, the total weight was 11,044 kilograms (24,347 pounds) with 742 hours spent at sea. On average, soaking of the seine during this period yielded 112 kilograms (247 pounds).

Additional seasonal trends at this landing site are as follows:

- In August to October 2019, the primary dry season and the closed trawl season, the total weight was 4,972 kilograms (1,095 pounds) with 362 hours spent at sea. On average, soaking of the seine in this period yielded 94 kilograms (207 pounds).
- In February 2020 and April 2019, 2 months of the secondary dry season, soaking of the seine during this period yielded, on average, 145 kilograms (320 pounds). Total effort and hauls could not be accurately presented for this period because the data pool for April 2019 (having commenced on 16 April) is relatively small and data were not collected for March 2020 to complete this season.
- In the January to February 2020 and April 2019 period, which is the first shrimp spawning season, soaking of the seine during this period yielded, on average, 131 kilograms (289 pounds). Similarly, total effort and hauls were not presented for this period because the data pool for April 2019 is relatively small and data were not retrieved for March 2020 to complete this season.

- In the June to July 2019 period, which is the second shrimp spawning season, the total weight was 12,826 kilograms (28,276 pounds) with 284 hours spent at sea. On average, soaking of the seine during this period yielded 327 kilograms (721 pounds).
- In the May to July 2019 period, the primary wet season, the total weight was 16,132 kilograms (35,565 pounds) with 139 hours spent at sea. On average, soaking of the seine during this period yielded 416 kilograms (917 pounds). In addition, the two most productive months, May and July, were part of this season.
- In November 2019 to January 2020 period, the secondary wet season, the total weight was 5,324 kilograms (11,737 pounds) with 420 hours spent at sea. On average, soaking of the seine during this period yielded 96 kilograms (212 pounds).

It is particularly illustrative of the various seine types used by the onboard supervisor that the seasonal trends aligned closely with the good and hard seasons for fishing instead of shrimping. The greatest total haul of white belly shrimp was also recorded in May 2019, at the commencement of the good season for fishing that is between the months of May to September 2019. Based on the other seasonal trends examined, the greatest productivity was observed in the wet seasons May to July 2019 and second spawning season June to July 2019. The greatest effort was expended in the secondary wet season November 2019 to January 2020, while the lowest effort was expended during the primary wet season May to July 2019. However, it should be noted that the second spawning season significantly overlaps with the primary wet season. Productivity also peaked in May and July 2019 at the La Grange landing site (Region 3) where Cadell lines are the principal fishing methods used.

Increased productivity during the wet seasons may also be related to the proximity of the fishing grounds to the mouth of the Demerara River. In the May to July primary wet season, increased nutrients flow from the mouth of the Demerara River and may influence the feeding behaviors of fishes by attracting greater quantities of fishes to these areas, leading to increased productivity.

2.4 Biometrics

The onboard supervisor measured the average lengths and weights of representative fishes of the species caught per fishing trip. Annual average lengths and weights indicate that both mature and immature fishes were caught (Figure M-6). The mature species included gillbacker, cuirass, trout, highwater, cuma cuma, and sea catfish that had annual average lengths of 71, 64, 57, 51, 29, and 29 centimeters, respectively. These fishes were likely caught by fishing methods other than the Chinese seine, as generally the mesh sizes of 2.5 to 10 centimeters (1 to 4 inches) would have been too small to allow for capturing the larger fishes. In addition, with annual average lengths of 8 centimeters and 5 centimeters, netly and mullet were considered to be mature. Finally, the annual average lengths of bangamary indicate that these fish were sexually mature. However, the annual average lengths of small banga demonstrated that the fishes classified were juveniles. Based on observations by the study team, small fishes discarded as bycatch were principally juveniles of their species.

The average monthly lengths of bangamary, sea catfish, and cuirass caught over the study period were all considered mature (see Figure M-7). However, the sizes of these fishes were observed to increase as the year progressed with the largest fishes all caught in the hard season. This is unusual and does not follow the trend observed at other landing sites where larger fishes are observed in the July to September spawning season, following which size decreases. The onboard supervisor from the La Grange landing site (Region 3) also recorded the largest sea catfish (caught from Cadell lines) in February 2020. Size increases for cuirass as the year progresses could be attributed to their seasonality, as the mating season for these fishes is during the secondary wet season. Further research is required to ascertain why

size variability of fishes caught at this landing site was not consistent with seasonal patterns observed elsewhere.

3 QUALITY ASSURANCE/QUALITY CONTROL DATA

During the first quality assurance/quality control (QA/QC) exercise conducted in September 2019, one of the fishing trips conducted by the onboard supervisor's vessel was assessed. During the trip, the vessel used an outboard engine of 40 hp and spent 12 hours at sea. During the time at sea, the Chinese seine was soaked one time. The species diversity for the trip was five (Figure M-8), which was lower than the species that were reported caught during the July to September reporting period. Most of the species caught were fishes and this is similar to the trends observed in the data collected for the July to

[3] Weights of individual Small Banga are too low to be measured with the scales used by the field team.

September study period, where fishes comprised the majority of the haul. However, the study coordinator observed that juveniles of four different species were categorized as small banga by the onboard supervisor. These species were snapper, bangamary, butterfish, and Chinese butterfish juveniles. As seen on Figure M-9, the fishes collectively referred to as small banga were extremely small as biometric measurements conducted by both the onboard supervisor and the study coordinator recorded lengths of less than 10 centimeters. The bycatch caught was not brought to shore as sorting or "picking" of the commercial species from bycatch was done offshore on the vessel.

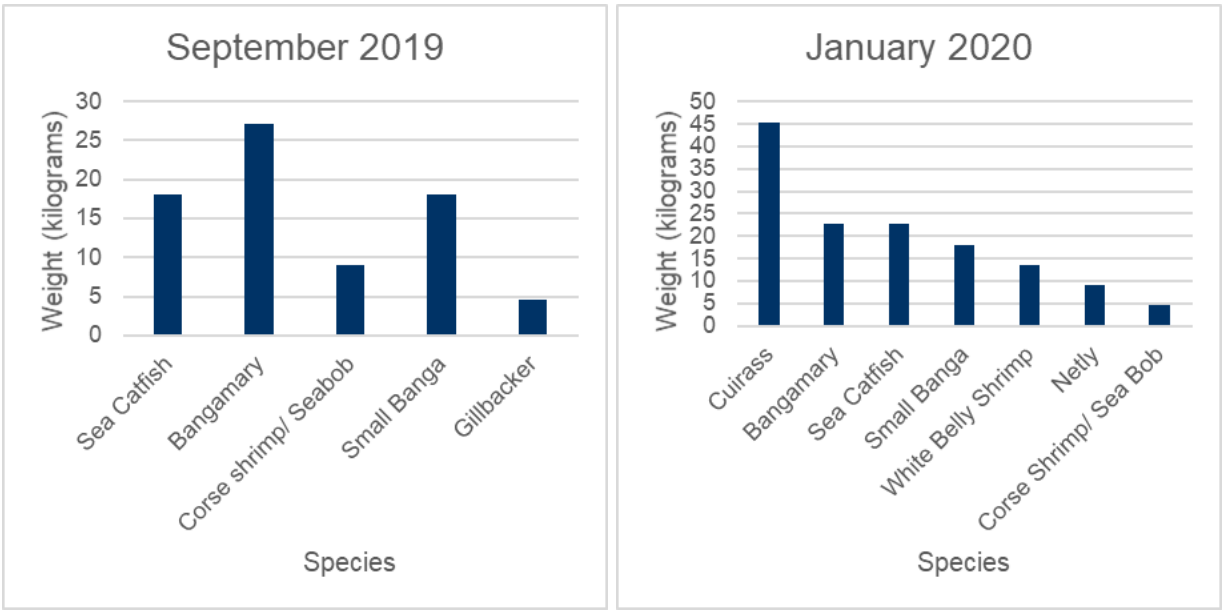

Figure M-8: Catch Composition of Commercially Viable Species during the QA/QC Exercises

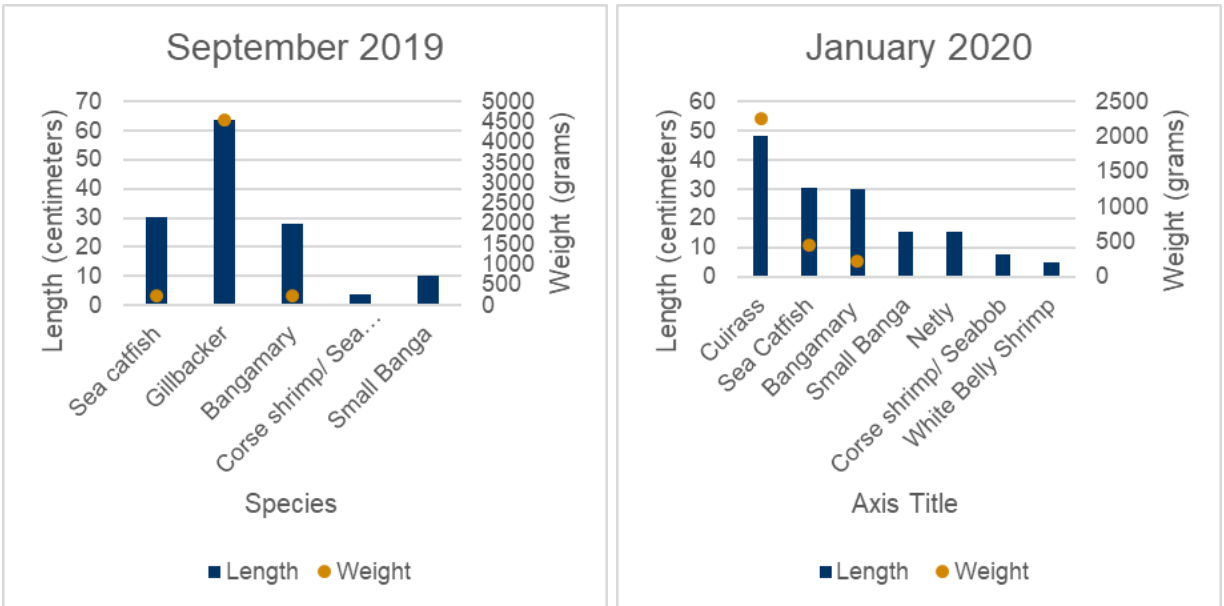

Figure M-9: Lengths and Weights of Species Measured during the QA/QC Exercises

During the second QA/QC exercise in January 2020, a GoPro camera was mounted on the onboard supervisor's vessel (see Figure M-10). Several key observations were made from the video monitoring:

- Similar to the onboard supervisor at the Ogle landing site (Region 4), Chinese seine fishing was complemented by the use of Cadell lines. This accounts for the relatively high catch percentage of sea catfish in the onboard supervisor's hauls.
- The vessel took 1 hour to travel from the Windsor Forest landing site to the Chinese seine pen used on the day that the QA/QC exercise was conducted. However, while en route to the pen, the supervisor stopped to soak the approximately 100 Cadell lines approximately 15 minutes away from where the Chinese seine was soaked.
- The Chinese seine was soaked for 3 hours while the Cadell lines were soaked for 6 hours.
- A large amount of bycatch comprised principally of jelly fishes and silverbelt and other species of mainly juvenile fishes was "picked" from the commercial haul while at sea. The supervisor carried a sorting board on the fishing trip that was used to sort the fishes. All bycatch was thrown into the sea.
- A total of seven commercially viable species were caught, most of which were fishes. Only two species, sea catfish and cuirass, were caught using the Cadell lines. This is consistent with the findings of the first QA/QC exercise and the catch composition reported by the onboard supervisor.
- Similar to the Ogle landing site (Region 4), when the bycatch is thrown into the sea, a number of sea birds would come to the area to feed.

In total, the supervisor collected 136 kilograms (79 pounds) of haul during the second QA/QC exercise. This was 28 kilograms (62 pounds) greater than the average catch recorded by the supervisor in January 2020. In addition, white belly shrimp accounted for 11 percent of the total haul, similar to the findings of the QA/QC exercise at Zeeburg landing site (Region 3). The onboard supervisor indicated that the productive season for white belly shrimp was expected to commence soon.

From the biometric data collected, the data collected by the onboard supervisor in January 2020 aligned completely with that collected during the QA/QC. Average lengths of bangamary were 29 centimeters based on data collected by the onboard supervisor and 30 centimeters during the QA/QC exercise. Sea catfish measured 30 centimeters in both instances. However, small banga and cuirass measured during the QA/QC exercise were 12 and 75 centimeters, respectively, compared to average lengths of 15 and 59 centimeters based on data collected from the supervisor. However, this variance is not a cause for significant concern. Overall, the study coordinator was satisfied that the onboard supervisor was accurately recording the commercial species caught and following the guidance provided in taking biometric measurements.

Figure M-10: Mounting the GoPro Camera on the Onboard Supervisor's Vessel at the Windsor Forest Landing Site

APPENDIX N RIVERVIEW (UNITY, MAHAICA) (REGION 4)

1 LANDING SITE OVERVIEW

Riverview (Unity, Mahaica) is one of the largest landing sites in Region 4. Fisherfolk estimate that approximately 30 vessels, all of which are outboard cruisers equipped with engines ranging from 5 to 48 hp, utilize this landing site. Most vessels use drift seines with mesh sizes of 7 centimeters (2.75 inches), known as bangamary seines, to target bangamary. A few vessels use drift seines with mesh sizes of 10 centimeters (4 inches) to target snapper. In addition, some vessels use both types of seines on an alternating basis. Approximately 0.5 kilometer west of the main landing area is another site on the foreshore used primarily for boat building and repairs, and infrequently as a landing area.

Vessels from this landing site fish along the coast of Regions 4 and 5. Generally, larger vessels have engines of at least 40 hp and make fishing trips that last for up to 3 days. These vessels also use drift seines of 10 centimeters (4 inches) to target trout and to a lesser extent snapper. By contrast, smaller vessels have engine sizes of less than 40 hp and make trips lasting approximately 12 hours using bangamary seines. Depending on the engine size of the vessel, fishing occurs approximately 1 to 25 kilometers from the coastline at depths of 2 to 28 meters. Seines are soaked from 3 to 10 hours per fishing trip. Typically, the larger vessels expend more effort per fishing trip by traveling farther offshore and spending longer at sea. These vessels also target higher-value species like snapper and trout.

Fisherfolk indicated that the main challenges they encounter are rough seas, sharks destroying seines when they are set, and conflicts with trawlers that at times sail over seines, which destroy them, cause loss of catch, and require significant seine mending. Fisherfolk have contended that trawlers intentionally destroy seines because they compete for preferred fishing grounds.

2 REGIONAL SUPERVISOR RESULTS

At the outset of the project, fisherfolk were reluctant to volunteer as regional and onboard supervisors citing various reasons, foremost of which was the belief that the data collected could be used to adversely affect fishing activities at the landing site. One regional supervisor was selected to participate in the study but challenges occurred when the study team determined that the regional supervisor was falsifying data, with the consequence that data collected during July to early September were not credible. As such, this final report does not include data for the July to September period as collected by the regional supervisor. Another volunteer was trained as the regional supervisor and data collection resumed in October of 2019.

2.1 Effort and Haul

Over the periods for which data were collected, an average fishing trip lasted 43 hours from April to June, 2019, and 31 hours from October 2019 to February 2020 (Figure N-1). The greatest effort was expended in April 2019 when a fishing trip lasted for more than 2 days on average. Lower effort was consistently expended during the October 2019 to February 2020 period when a fishing trip lasted for approximately 30 hours on average. The increased effort in the April to June is attributed to calmer waters during this period that allowed fisherfolk to stay out longer at sea.

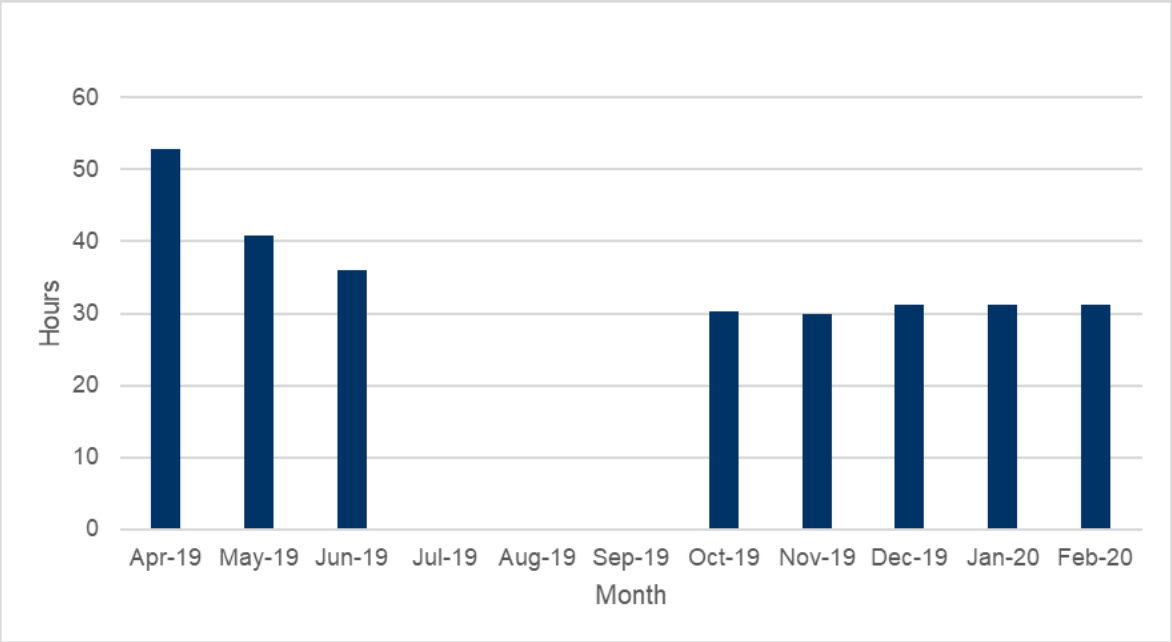

Figure N-1: Average Monthly Fishing Effort at the Riverview Landing Site

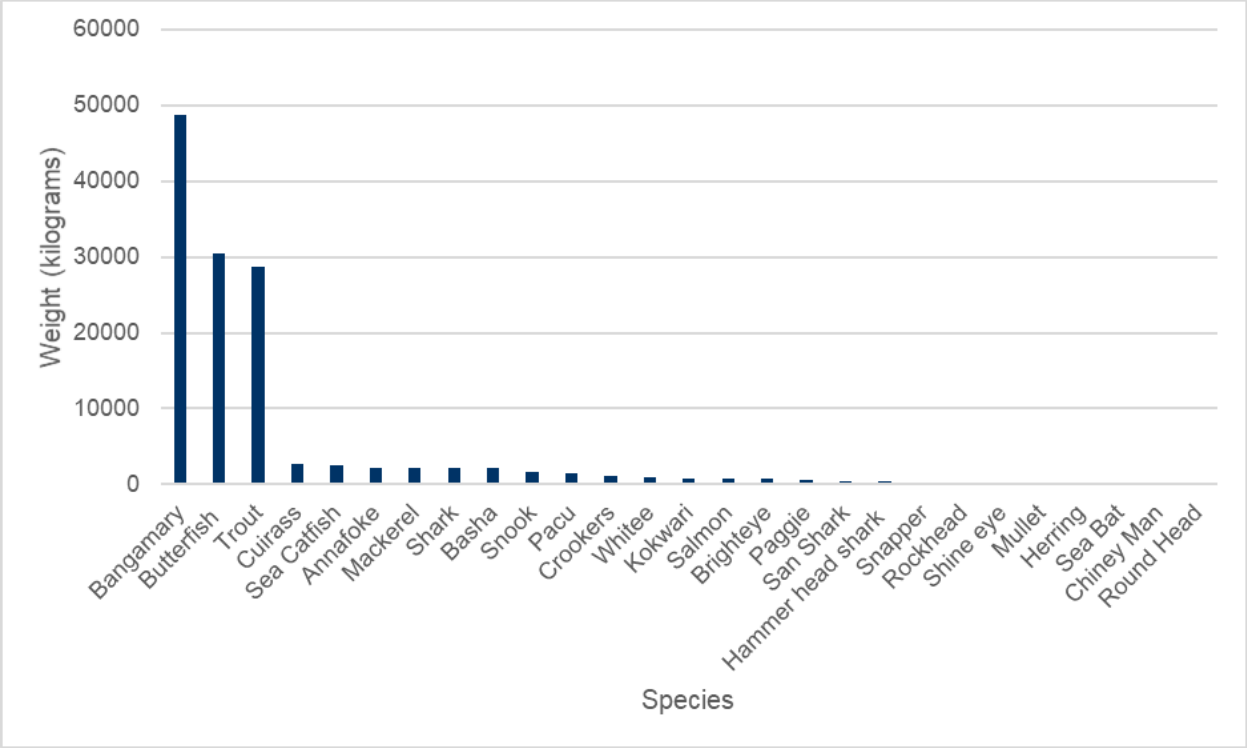
Based on the data collected by the regional supervisor, 54 different species of fishes were caught with a total weight of 133,977.5 kilograms (295,369 pounds). If data were included for the July to September period, it is expected that the total weights of fishes caught would have significantly increased. As seen on Figure N-2, bangamary was the most abundant species caught by weight with a total of 48,719 kilograms (107,407 pounds) taking up 36 percent of total haul. The second and third most abundant species caught were butterfish and trout with total weights of 30,532 kilograms and 28,765 kilograms (67,312 pounds and 63,416 pounds), respectively which represented 23 and 21 percent of total weight of fishes caught at this landing site. This pattern was expected, as bangamary is overwhelmingly the most abundant species caught in “bangamary seines”, followed by smaller quantities of butterfish and trout. A similar species distribution is also observed in data collected by the onboard supervisor at this landing site and by the regional supervisor at the Mahaicony Bridge landing site (Region 5) where data were reported exclusively for hauls from bangamary seines. Cuirass was the fourth most abundant species caught at the Riverview landing site. However, with total weights of 2,626 kilograms (5,789 pounds), it was caught in significantly lower quantities than bangamary, butterfish, and trout.



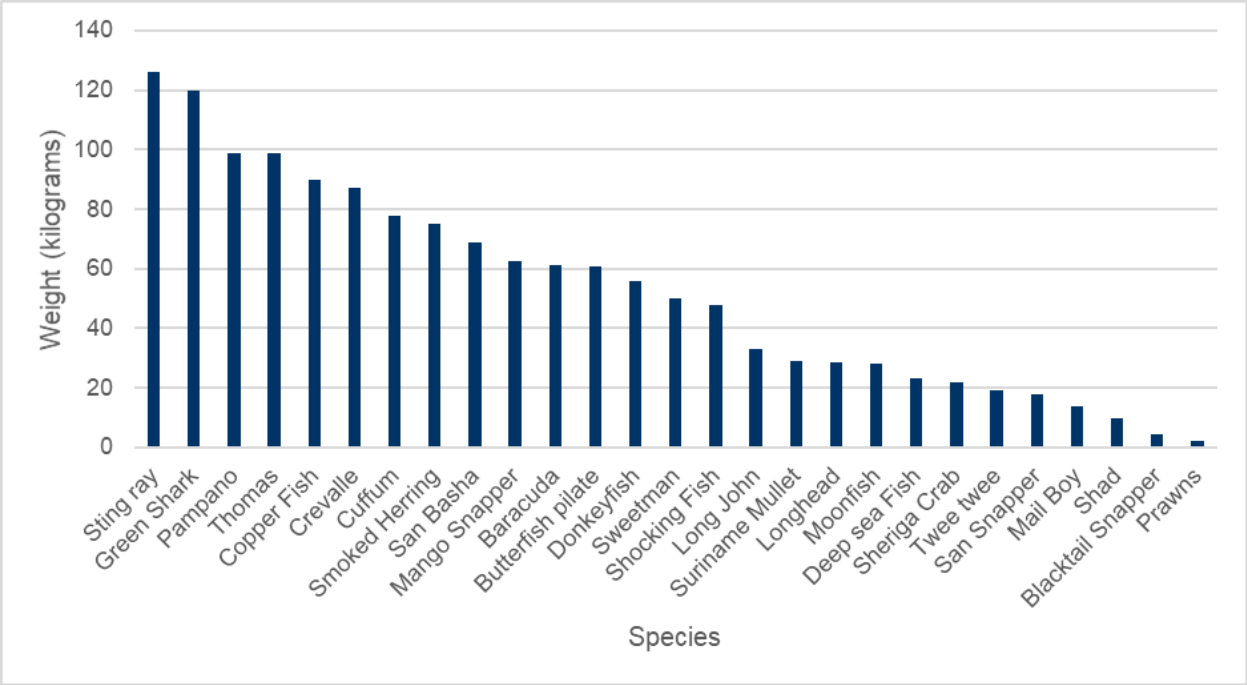


Figure N-2: Total Weight of Species Caught at the Riverview Landing Site

2.2 Target Species and Diversity

Although a total of 54 commercial species were caught at this landing site, 36 were caught in low quantities with an aggregated total weight of 500 kilograms (1,102.3 pounds), several of which were not reported at any of the other landing sites included in the study. Moreover, multiple species within a single

species group were also reported at this landing site. For example, several species of snapper were reported including (grey) snapper, mango snapper, san snapper, and blacktail snapper. Similarly, several species of shark were reported including green shark, sand shark, other shark species (includes several species, including blacktip shark at this landing site, which is an endangered, threatened, or protected species), and hammerhead shark (some species of which are classified as vulnerable by the IUCN). Species of shark caught at other landing sites were not reported and the species reported by the Riverview regional supervisor are likely representative of species commonly caught by artisanal fisherfolk elsewhere. Stingrays, some endangered, threatened, or protected species, were also recorded in the hauls.

Nearshore species, such as pacu, and species found on mudflats, such as sheringa crabs, were also reported in the hauls from this landing site. No gillbacker was reported at this landing site and the reason for this is not clear. Large quantities of bycatch were not reported at this landing site and this may be attributed to the relatively large mesh sizes of the seines used.

Species diversity of hauls was observed to change seasonally with a greater number of species caught in the October 2019 to February 2020 period, than in the April to June 2019 period (Figure N-3). This may be attributed to changed fishing practices during the hard season from October to February 2020 and the good season in April to June 2019. In particular, hauls in the hard season included fishes typically caught farther offshore, such as sand sharks, green sharks, and deep-sea fish compared to fishes reported in the good season. By contrast, in the good seasons, fisherfolk have reported achieving optimum hauls without needing to travel as far offshore. Seasonal variations in the productivity at the landing site are discussed further below. The seine size, which is considered a mid-range size, allows for a wide variety of fishes of varying sizes to be caught. Moreover, like Smith's Creek and Morahwanna, several migratory species were caught during October 2019 to December 2019 including pompano, moonfish, and chiney man. These migratory species were only reported by the regional supervisors at this landing site, and at Smith's Creek and Morahwanna.

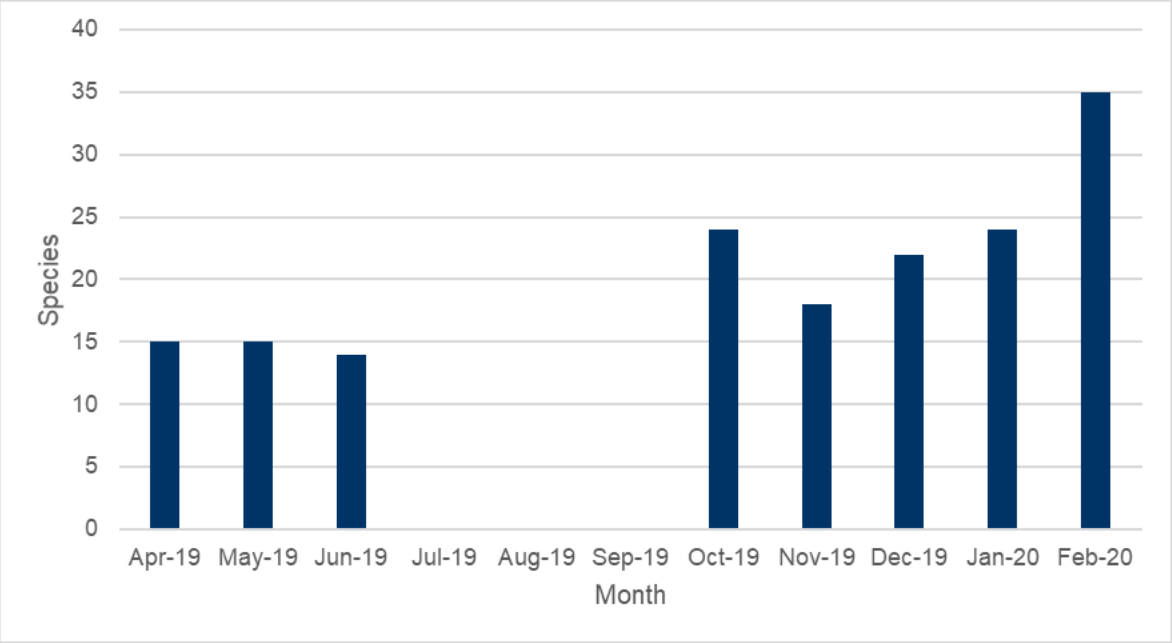

Figure N-3: Species Diversity at the Riverview Landing Site

2.3 Seasonal Productivity

As previously discussed, fisherfolk contend that the peak season for fishing activities occurs from May to September and the off-peak season from October to April. Although there is a data gap for July to September 2019 at this landing site, this seasonal variation in productivity appears to hold true for this landing site (Figure N-4). Average productivity consistently increased from April to June 2019 with a peak in June. Based on data available, average productivity sharply declined from October 2019 to February 2020. Overall, combined average productivity for the 2-month period of May to June 2019 was 1,499 kilograms (3,305 pounds) and was higher than combined productivity for the 6-month period of October 2019 to February 2020 and April 2019, with 1,389 kilograms (3,062 pounds). If data were available for July to September 2019 (the remaining months of the good season) the difference in productivity would likely have been significant. Seasonal productivity at this landing site has no discernible trend based on Guyana's wet and dry seasons and the data gap for July to September 2019 hinders a robust comparative analysis.

It should be noted that data collected by the onboard supervisor at this landing site (Section 4.2), showed a similar trend of consistently increasing productivity from April to June. For the onboard supervisor, this was followed by a peak in July 2019 after which productivity sharply declined and remained low until February 2020. Most vessels at this landing site would likely have adhered to this trend, and productivity at the landing site would have peaked in July 2019. Additional data are required to better understand seasonal productivity of fishing activities at this landing site.

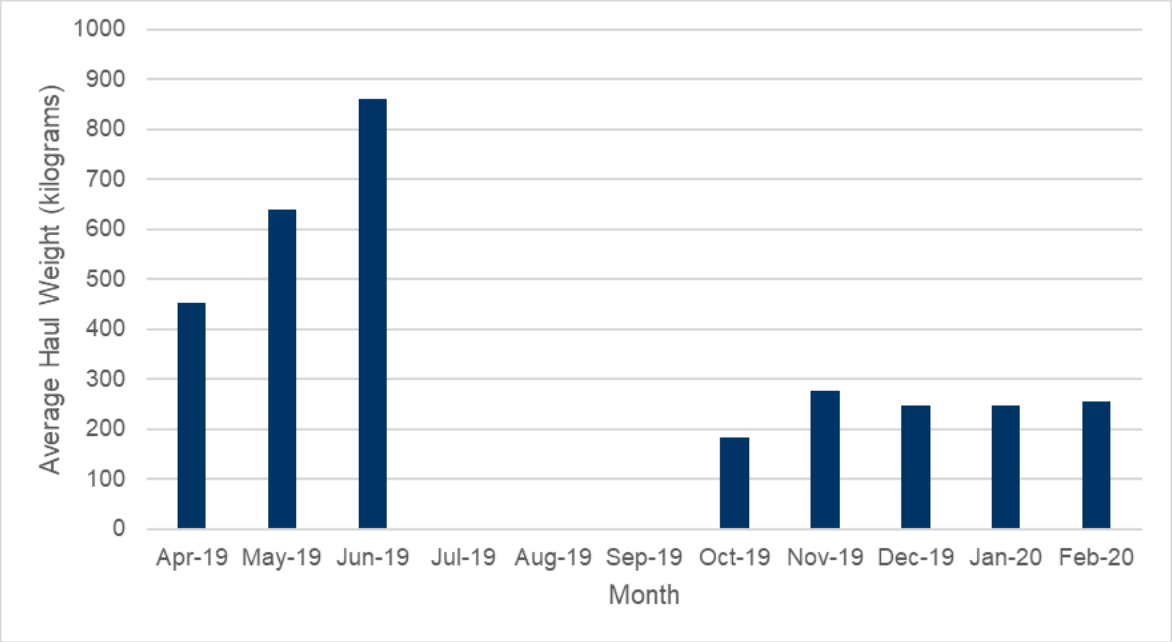

Figure N-4: Average Monthly Productivity of Fishing Trips at the Riverview Landing Site

2.4 Prices and Markets

Similar to most of the landing sites in the study, snapper are the highest-value fishes at this landing site. Based on the data collected by the regional supervisor, the blacktail snapper was the highest-value species with an annual average price of $750 GYD per kilogram ($3.60 USD per kilogram) as seen on Figure N-5. This was the least abundant species caught with a total haul weight of 4.5 kilograms

(10 pounds) during the 8 months for which data were collected, and this may have also contributed to the high price at which it was sold. Grey snapper, commonly referred to as snapper, was the second highest-value species with an annual average price of $679 GYD ($3.30 USD). The two other snappers, the mango snapper and san snapper, were recorded by the regional supervisor and were medium-value species with annual average prices of $191 GYD ($0.90 USD) and of $132 GYD ($0.60 USD), respectively.

Species valuation at this landing site is also demonstrably different than from those at other landing sites. Sea bats, which would not be considered commercially viable at most of the landing sites in the study, were the fourth highest-value species with an annual average price of $661 GYD ($3.20 USD). Sharks were also highly valued at this landing site with the green shark being the third highest-value species with annual average prices of $390 GYD ($1.90 USD). Sand shark and hammerhead shark were also high-value species, and the blacktip shark was an upper medium-value species. This is uncommon as sharks were low-value species at other landing sites where it was reported such as Smith's Creek and Morahwanna (Region 1); Charity (Region 2); and Mahaicony Bridge (Region 5) where annual average prices were $157 GYD ($0.8 USD); $129 GYD ($0.6 USD); and $216 GYD ($0.96 USD), respectively. Bangamary, the target species of most fisherfolk at this landing site and the most abundant species caught, was a medium-value species with annual average prices of $223 GYD ($1 USD). The two secondary target species, butterfish and trout, were more highly valued with annual average prices of $345 GYD ($1.70 USD) and $620 GYD ($3 USD). Although glue from trout and snapper are high value and high demand, there is no established market for these by-products at this landing site because fishes are typically sold un-gutted. Approximately 14 species were low-value at this landing site with annual average prices of less than $100 GYD ($0.48 USD) per kilogram, all of which were also infrequently caught. In total, fishes sold at this landing site were valued at $45,323,998 GYD ($217,904 USD).

Fishes landed at this site are sold to trucks that visit the landing site on a daily basis. Vendors from these trucks typically buy the target species of bangamary, butterfish, and trout, and high-value species such as snapper and shark. Vendors both export fishes and sell in local marketplaces. Locals from Riverview and other neighboring communities also visit the landing site to purchase fishes directly from fisherfolk when the vessels land. Although 54 species were considered to be commercially viable by fisherfolk, there were only markets for 50 species. Species for which there were no markets included sheringa crabs, donkey fish, prawns, and stingrays. Although there were also no markets for stingrays at this landing site, these were sold at Smith's Creek and Morahwanna as a lower-value species in those markets. Species not sold would either be donated to locals or used by the fisherfolk who caught them.

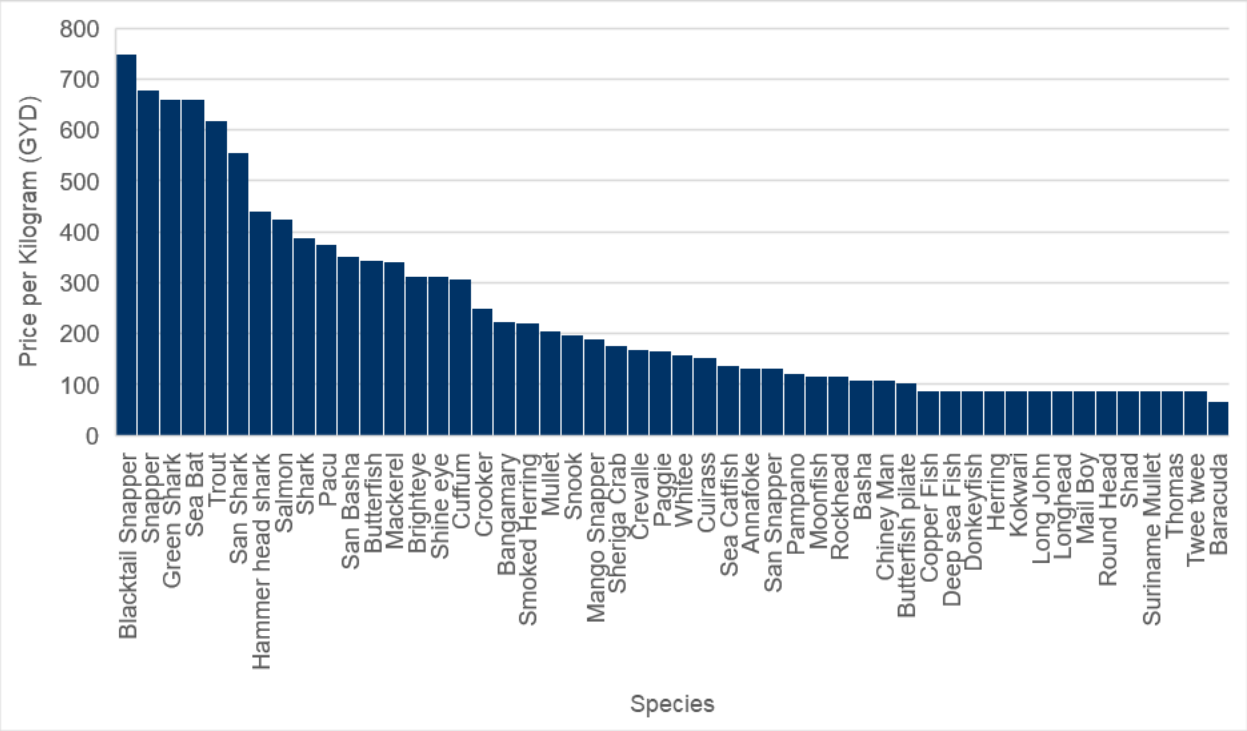

Figure N-5: Annual Average Prices of per Kilogram Fishes Sold at the Riverview Landing Site

The minimum, maximum, and average prices for the four most frequently-caught species are shown on Figure N-6. Average prices for bangamary and butterfish were relatively stable while average prices for trout and cuirass fluctuated significantly throughout the year. Most of the price variances at this site can be attributed to bargaining among fisherfolk, vendors, and local community members who visit the landing site to purchase fishes. In addition, seasonal changes in prices may be influenced by the interplay of demand and supply for fishes on a seasonal basis.

Maximum and average prices for bangamary peaked in May 2019 and subsequently dipped, remaining relatively low throughout the hard season. Similarly, the highest prices for trout were observed during the good season but then declined and remained consistently low throughout the hard season. This trend in pricing for trout was also observed at the Charity landing site (Region 2) where the lowest prices were recorded during the October 2019 to February 2020 hard season. In addition, at the Mahaicony Bridge landing site (Region 5), prices for trout declined after June 2019 and remained at consistently low levels throughout the year. It is likely that this was influenced by a decline in the demand for glue harvested from un-gutted trout due to an increased supply in the local markets during the peak season. Pricing in general follows demand and supply rules unless affected by fuel pricing. The demand is influenced by both international and local markets and marketing practices. Price declines for bangamary were also observed at the Mahaicony Bridge landing site (Region 5) in June 2019. This was also linked to increased supply leading to price reduction during this season.

By contrast, maximum prices for butterfish peaked in May and June 2019, and average prices remained at the highest levels during the hard season because there is greater demand for butterfish than bangamary, particularly given its relative scarcity. However, there was a sharp decline in February 2020. Prices for cuirass were significantly higher during the hard season; however, the reason for this trend is unknown.

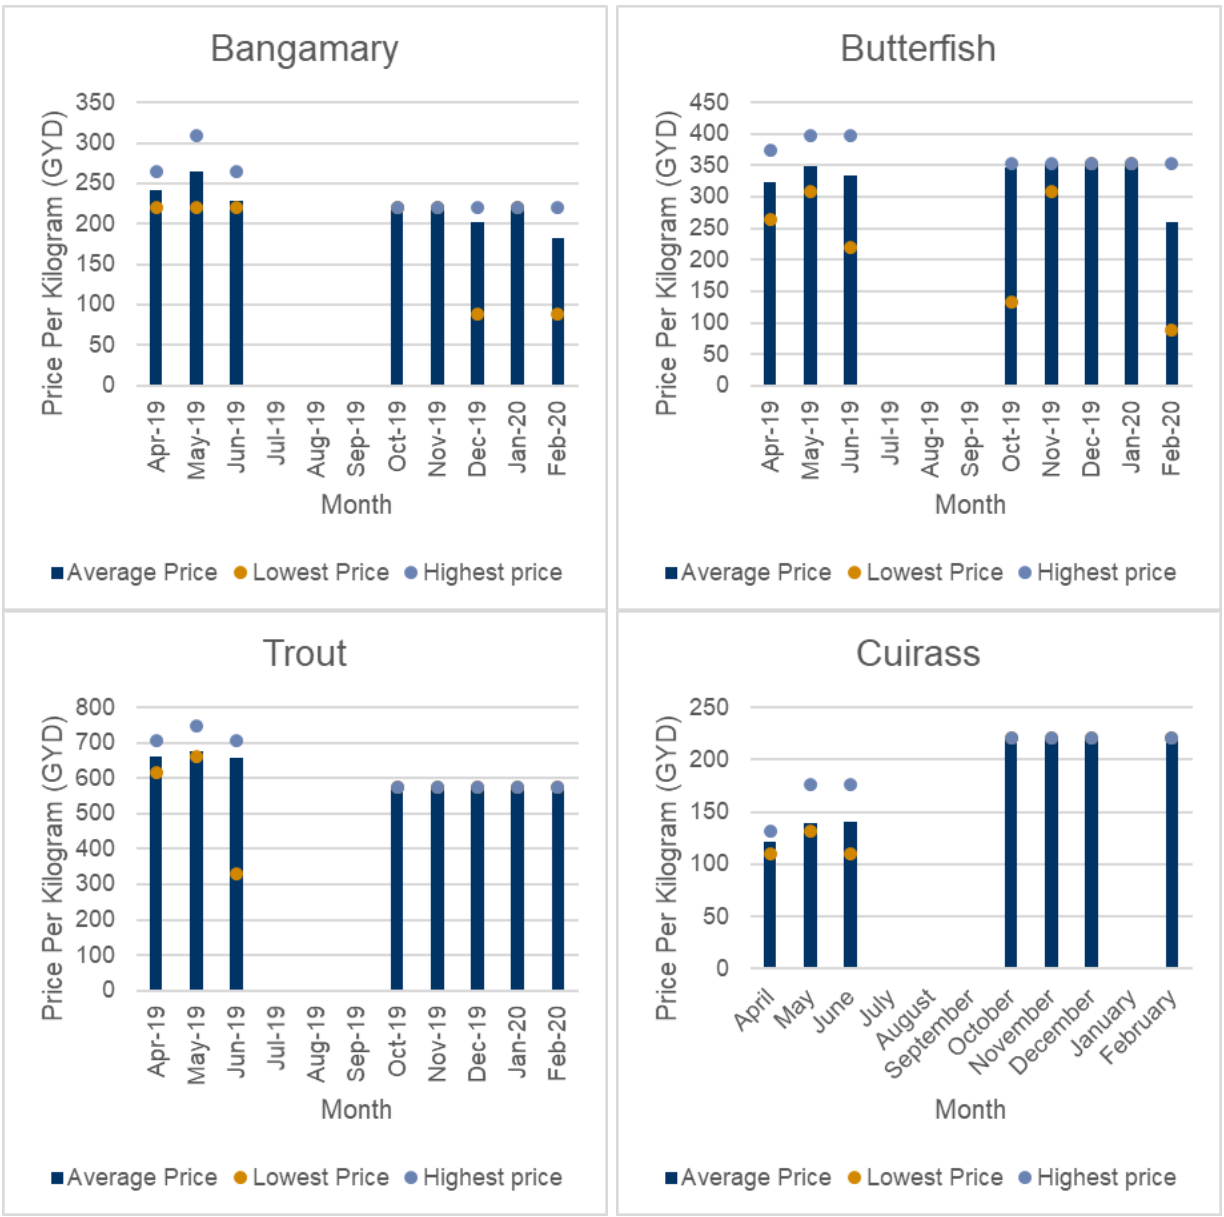

Figure N-6: Monthly Price Variations of the Four Most Abundant Fishes Caught at the Riverview Landing Site

2.5 Biometrics

The regional supervisor measured the lengths and weights of fishes that were representative of hauls for which data were collected. The annual average length and weight of these fishes are presented on Figure N-7. The largest fish caught was the blacktip snapper, which had an annual average length of 74 centimeters and annual average weight of 4,536 grams. The smallest fish species caught was the smoke herring, which had an annual average length of 20 centimeters and annual average weight of 113 grams.

Most of the species caught at this landing site had achieved sizes of sexual maturity with the exception of the shark species, all of which were immature:

- The blacktip shark, an endangered, threatened, or protected species, are sexually mature at 157 centimeters, but species recorded had an annual average length of 45 centimeters.
- The hammerhead shark, some species of which are considered vulnerable by the IUCN, are sexually mature at 90 centimeters, but species recorded had an annual average length of 42 centimeters.
- The sand shark and green shark are sexually mature at 72 centimeters and 159 centimeters, but species recorded had an annual average length of 43 centimeters and 40 centimeters, respectively.

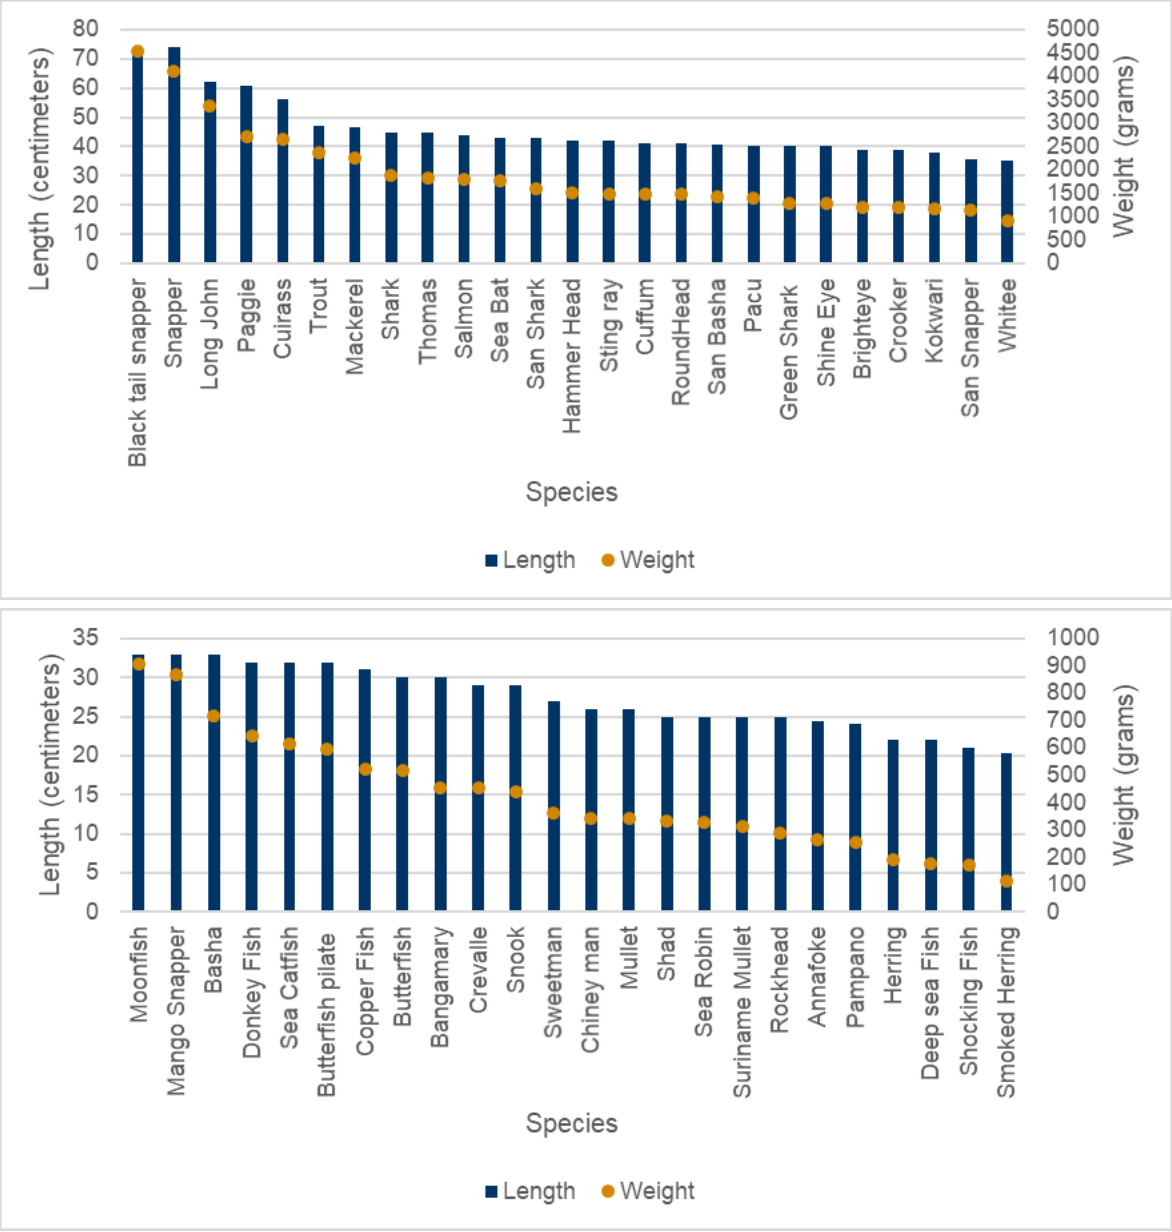

Figure N-7: Annual Average Lengths and Weights for Fishes Measured at the Riverview Landing Site

There is some variability in the monthly average lengths and weights of the four most abundant species caught (Figure N-8), but most of the species were considered sexually mature. The largest fishes of the

four most abundant species caught were recorded from April to June. Fishes were significantly smaller in the October 2019 to February 2020 period. Marginal increases in size were observed during the hard season. For example, larger fishes were recorded in November 2019 for all species but there was no common trend in size variations on a monthly basis. This is similar to the data collected by regional supervisors at the landing sites in Smith's Creek and Morahwanna (Region 1), Charity (Region 2), and Mahaicony Bridge (Region 5), all of which use drift seines in their fishing activities.

Seasonal variability in the fishing activities may be attributed to two factors. First, fisherfolk come closer to shore during the rainy seasons because nutrient flow is increased in these areas and trade winds are lower, which also supports their movement. This supports observations of larger fishes of the four most abundant species caught that were recorded in the rainy seasons for which data were collected. Regional supervisors in Regions 1, 2, and 5 also reported larger fishes caught in July and September as the good season progressed; this may be attributed to these fishes coming closer to shore to spawn in the estuaries. If data were available for the July to September 2019 period at the Riverview landing site, it is expected that it would have followed these trends of larger fishes being caught.

During the April to June 2019 period, the supervisor collected data from more vessels using drift seines with mesh sizes of 10 centimeters (4 inches) than in the October 2019 to February 2020 period when data were collected from more vessels using seines with mesh sizes of 7 centimeters (2.75 centimeters). Drift seines with larger mesh sizes capture larger fishes and this may have also partially contributed to larger fishes being reported from April to June 2019. Nonetheless, although smaller fishes were reported in the hard season, fishes were generally sexually mature.

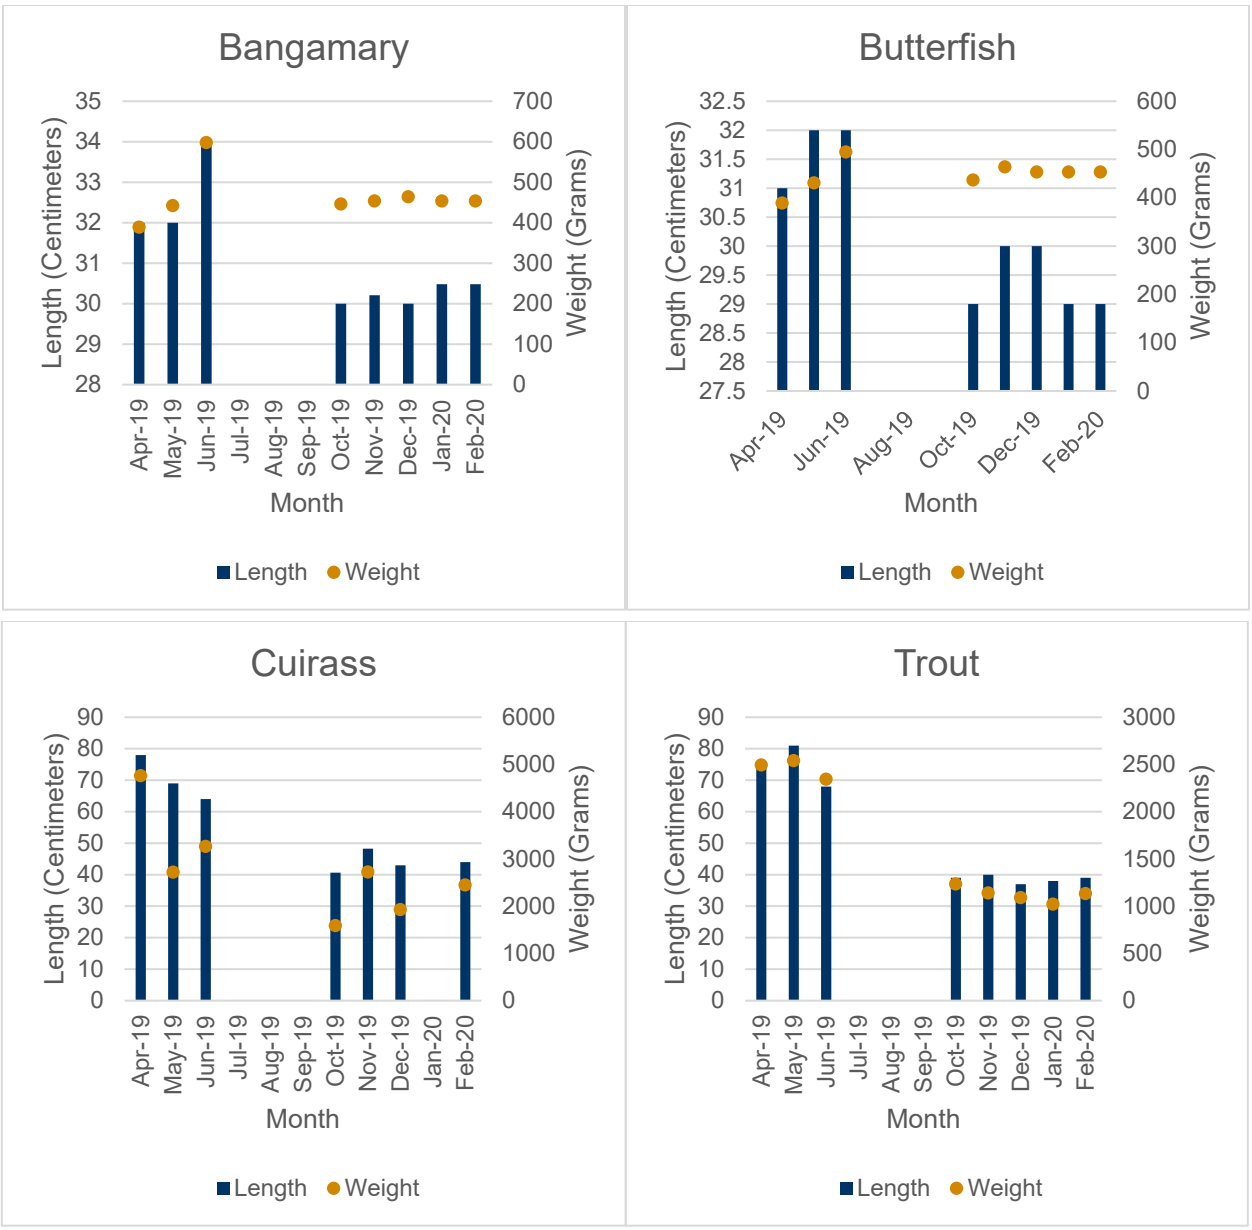

Figure N-8: Monthly Average Lengths and Weights of the Most Abundant Species Caught

3 ONBOARD SUPERVISOR RESULTS

At the outset of the project, fisherfolk were reluctant to volunteer as regional and onboard supervisors citing various reasons, foremost of which was the belief that the data collected could be used to adversely affect fishing activities at the landing site. Indeed, two individuals who volunteered as onboard supervisors and received training on data sheet completion and on the use of the GPS unit and digital camera, subsequently opted to withdraw. As a consequence, the onboard supervisor did not commence data collection until the end of April 2019.

The onboard supervisor at this site uses a drift seine with mesh sizes of 7 centimeters (2.75 inches), i.e., the “bangamary seines” to target bangamary. Typically, fishing trips last for 12 hours at sea. The vessel

has a haul capacity of 2,045 kilograms (4,508 pounds) and is powered by a 40 hp engine. Each fishing trip requires a two-member crew inclusive of the onboard supervisor. Fuel is the most significant expense per fishing trip for the onboard supervisor and generally, fishes are not iced before returning to shore. Most of the haul is sold to the vendors who visit the landing site with refrigerated trucks. During the study period, the most significant challenges faced by onboard supervisor were the proliferation of sargassum weed from February to May, which became entangled in seines resulting in reduced catch. Time is also lost as fisherfolk need to remove the entangled sargassum seaweed in seines, which is a time consuming exercise. In addition, over the months of September to November, a proliferation of 'slime' in the waters accelerated fish rot. Fisherfolk have reported that slime is commonly experienced at this landing site. Due to its role in rotting fish, slime may be bacterial, but its scientific name is unknown.

3.1 Fishing Area

The onboard supervisor has a traveling range of 1,041 square kilometers. The fishing points used by the onboard supervisor were comprised of two main clusters (see Figure N-9):

- The first cluster of points was located relatively close to the shore and covered an area of 163 square kilometers. These fishing grounds were used frequently during both the good and hard seasons. Overall, most of the fishing points in the hard season were in this cluster.
- The second cluster was located farther offshore and covered an area of 92 square kilometers. These fishing points were used mainly in the good season. Only four fishing points in this cluster were used during the hard season.

The farthest distance the onboard supervisor traveled was approximately 33 kilometers offshore during the hard season. The onboard supervisor indicated that the hauls from fishing points closer to the shore were not productive and as a result, the crew opted to brave rougher seas to fish farther offshore. The closest location to shore at which fishing occurred was 0.4 kilometer and this was also recorded during the hard season.

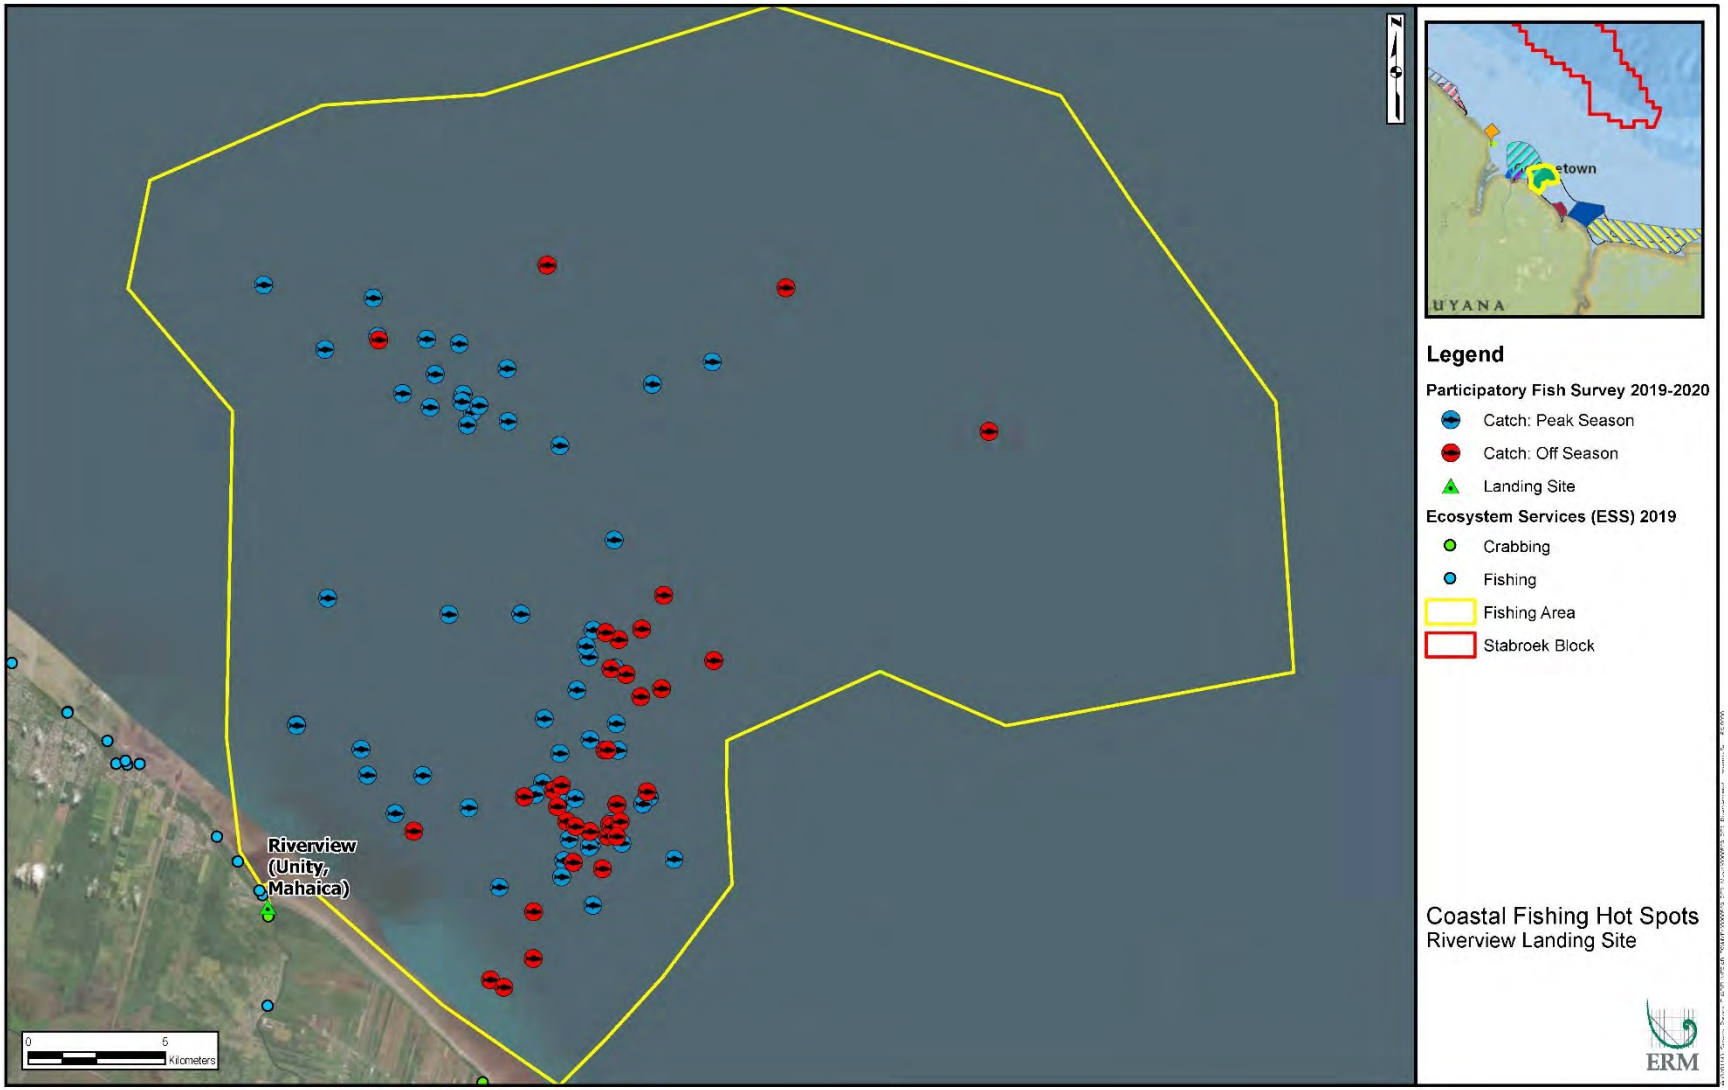

Figure N-9: Map of Fishing Area and Fishing Points Used by the Riverview Onboard Supervisor

3.2 Effort and Haul

The total weights of combined hauls from the onboard supervisor's vessel over the period April 2019 to February 2020 was 44,601 kilograms (98,328 pounds). Bangamary, the target species at this landing site, was the most abundant species caught by a significant margin (Figure N-10). The onboard supervisor caught a total of 23,936 kilograms (52,770 pounds) of bangamary representing 53 percent of the total haul. In addition, butterfish and trout were the second and third most abundant species caught with 6,379 kilograms (14,063 pounds) and 4,028 kilograms (8,880 pounds) caught, respectively. Bangamary, butterfish, and trout were also the three most abundant species caught at the Riverview landing site (as reported by the regional supervisor), and at every other landing site where the bangamary seines were used, namely Mahaicony Bridge (Region 5) and Albion (Region 6). The fourth most abundant species caught was sea catfish.

Overall, 56 different species were reported by the onboard supervisor. Of this, 47 species collectively represented less than 1 percent of the total haul. In spite of being caught in small quantities, these species are still deemed commercially viable. The onboard supervisor reported several of the species that were also reported by the regional supervisor at this landing site including several endangered, threatened, protected, and vulnerable species such as blacktip shark and hammerhead shark, and migratory species such as the moon fish and pampano. However, the onboard supervisor also caught additional species that were not reported by the regional supervisor for this landing site, such as swordfish and grouper. High-value fishes like snapper, gillbacker, and green shark were only caught in small quantities. Moreover, some of the highest-value species at this landing site like the blacktail snapper and sea bat were not caught by the onboard supervisor. The species composition showed that several smaller species were caught including annafokes, Suriname mullet, and prawns. This species diversity can be attributed both to the type of seine used and the species valuation at the landing site. Overall, given the wide range of species that are considered commercially viable at this landing site, bycatch quantities were low. When recorded, bycatch included sargassum, skates, and rays. Sea robin is also generally reported as bycatch, but is used on a subsistence basis by the onboard supervisor and other locals to whom they are donated.

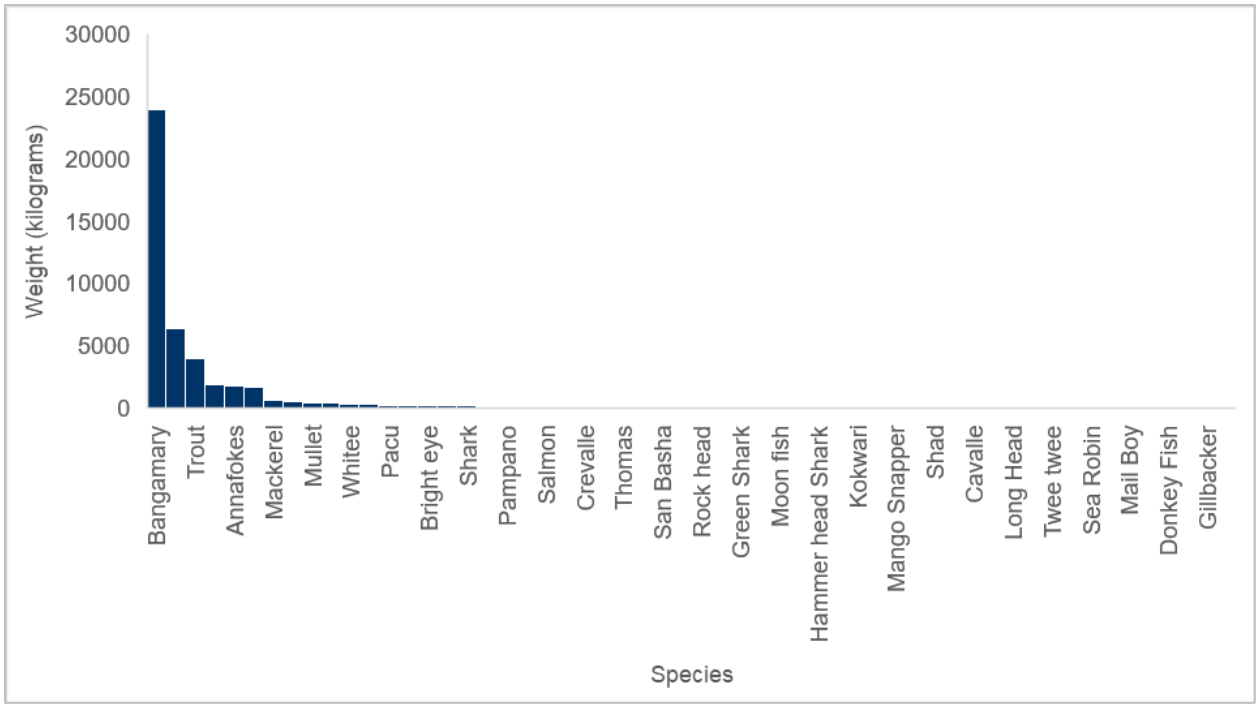

Figure N-10: Total Weight of Species Recorded by the Riverview Onboard Supervisor

3.3 Seasonal Productivity

The onboard supervisor, like the other artisanal fisherfolk included in the study, believes that there are good and hard seasons for fishing. According to these beliefs, May to September is the good season that peaks in July to September and October to March is considered the hard season. It is widely believed that waters are warmer and calmer during the good season, and these conditions are more conducive to fishing. These seasons are believed to influence effort expended by fisherfolk as well as hauls per soaking of the seine and per fishing trip.

During the study period, the onboard supervisor spent an average of 1,815 hours per month fishing, but the effort expended varied per fishing trip on a monthly basis as seen on Figure N-11. The onboard supervisor's monthly effort peaked in November 2019 with 210.5 hours of fishing activity. Several other onboard supervisors expended peak effort in November including at landing sites in Lima (Region 2), Windsor Forest (Region 3), La Grange (Region 3), and Ogle (Region 4). The lowest effort was expended in September 2019 when 81 hours were spent fishing. Although 13 hours were expended in April 2019, data collection did not begin until April 27, 2019, and as such, no comparable monthly data are available for this month.

As seen on Figure N-12 and Figure N-13, July 2019 was by far the most productive month when the highest average catch per soaking was 18,982 kilograms (41,484 pounds) and the greatest total monthly haul was 1,186 kilograms (2,615 pounds). The second most productive month was June 2019 when average catch per soaking was 315 kilograms (694 pounds) and total haul weight was 5,034 kilograms (11,098 pounds). Hauls in July 2019 were up to five times greater than June 2019 and over six times greater than the other months. Low hauls were consistently recorded from August 2019 to February 2020, although effort was high for most months during that period. The lowest total haul was seen in April 2019, but as previously noted, the data pool for this month is too small to be compared. Overall, the trends in productivity match those reported by the regional supervisor for this landing site. Similar to the trend

observed by the regional supervisor, hauls started to steadily increase in May and peak in July 2019. Hauls from the onboard supervisor sharply declined in August 2019 and stayed relatively low through February 2020. Trends at the landing site likely follow this pattern of low hauls over the August to September 2019 period.

Seasonal variations in effort and productivity were observed as follows:

- In the May to September 2019 good season the total weight of hauls was 30,810 kilograms (66,535 pounds) with 858 hours spent at sea. On average, soaking of the seine during this period yielded 398 kilograms (877 pounds). Total haul and average weight of hauls per soaking peaked in July 2019. In addition, May 2019 was the second most productive month. In both months, effort expended was in the upper range for this landing site with 186 hours in May and 206 hours in July. However, in September 2019, monthly effort and total haul were the lowest for the good season and were comparable to levels observed during the hard season. The reason for this dip is unknown. Similar trends were observed at the La Grange landing site (Region 3), with the key difference being that the dip in effort and productivity occurred in August 2019.

- In the October 2019 to February 2020 hard season, the total weight of hauls was 13,681 kilograms (30,161 pounds) with 944 hours spent at sea. On average, soaking of the seine during this period yielded 185 kilograms (408 pounds). Although the onboard supervisor expended the greatest effort in November 2019, total hauls and average weight of hauls per soaking declined compared to September. For November 2019, effort and total haul did not increase from October 2019, neither did it subsequently decline in December 2019. In addition, average hauls per soaking were consistently low for most of the hard season. Data for April 2019 were not considered, since the data pool is too small.

By comparison, seasonal trends in the wet and dry season were as follows:

- In the August to October 2019 period, which is the primary dry season, the total weight of hauls was 7,255 kilograms (15,995 pounds) with 443.5 hours spent at sea. On average, soaking of the seine during this period yielded 178 kilograms (392 pounds).

- In the May to July 2019 period, which is the primary wet season, the total weight of hauls was 26,477 kilograms (58,371 pounds) with 595 hours spent at sea. On average, soaking of the seine during this period yielded 555 kilograms (1,224 pounds).

- In February 2020 and April 2019, 2 months of the secondary dry season, total weight of hauls was 2,101 kilograms (4,632 pounds) with 201 hours spent at sea. On average, soaking of the seine during this period yielded 121 kilograms (267 pounds).

- In November 2019 to January 2020, the secondary wet season, total weight of hauls was 8,768 kilograms (19,330 pounds) with 575.5 hours spent at sea. On average, soaking of the seine during this period yielded 194 kilograms (428 pounds).

Based on the trends discussed above, the productivity of fishing activities was seasonal and adhered to the periods for good and hard seasons. Average haul per soakings were also greater during the good season as compared to the hard season. However, climatic seasonality also influenced productivity. The most productive seasons were the primary and secondary wet seasons. These were also the seasons in which the greatest haul per soaking and the greatest effort were expended by the onboard supervisor. This is unusual since, at most landing sites, greater productivity in the good season typically translates to the primary wet and dry seasons being the most productive.

At the landing sites in Rosignol (Region 5) and Complex 66 (Region 6), the hauls were more productive during the wet season. At those landing sites, uptick during the rainy season was likely attributed to fishing grounds being located at the mouths of rivers where feeding grounds are expected to be more fertile during the wet seasons. However, the closest major river to which the onboard supervisor fishes is the Demerara River, which is approximately 30 kilometers away. It should be noted that similar trends of productivity were not observed by the onboard supervisor from the La Grange landing site (Region 3) who utilizes fishing grounds offshore of the Demerara Rive mouth. Additional data are needed to determine whether these trends are typical for hauls from the onboard supervisor.

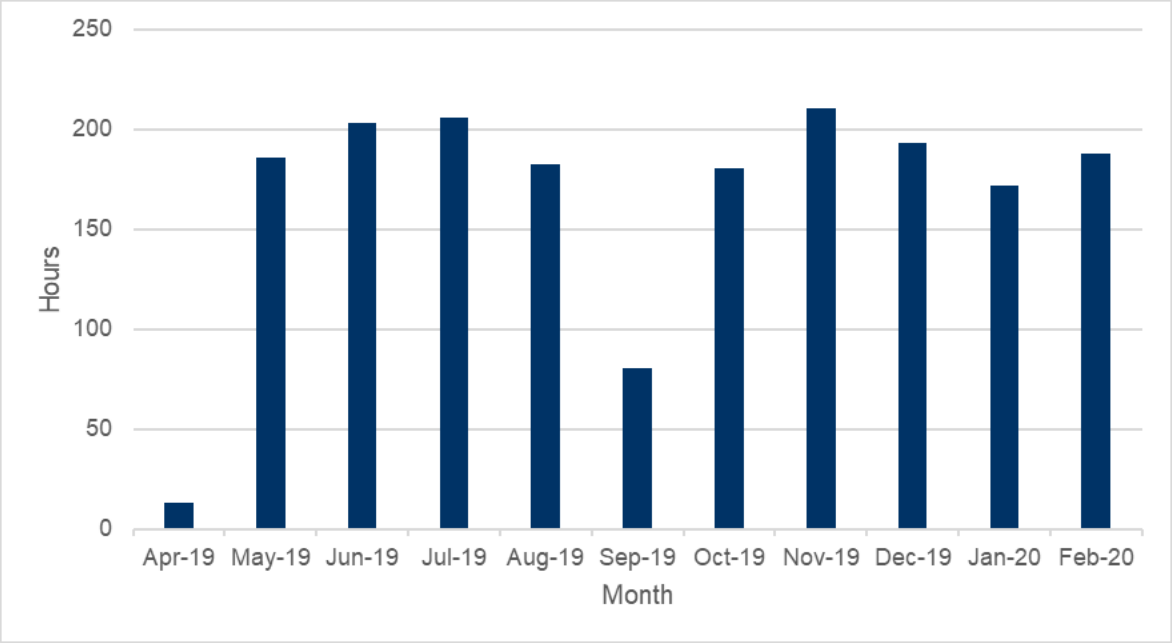

Figure N-11: Total Monthly Fishing Effort Recorded by the Riverview Onboard Supervisor

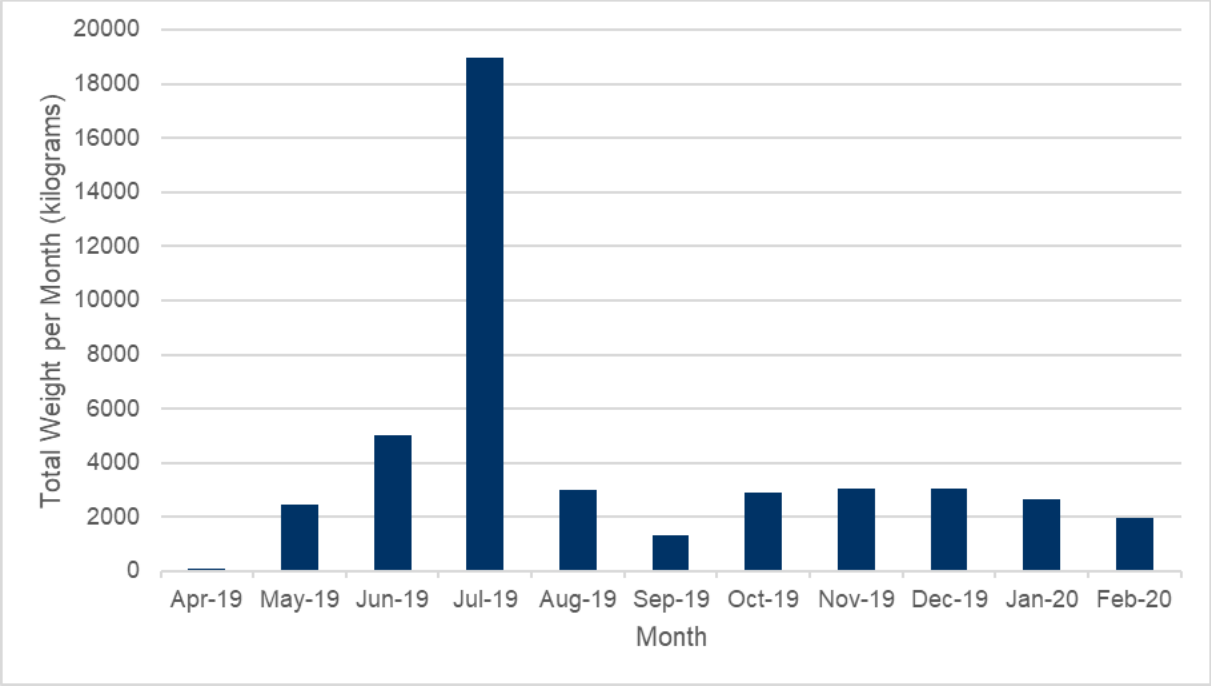

Figure N-12: Total Monthly Weight Recorded by the Riverview Onboard Supervisor

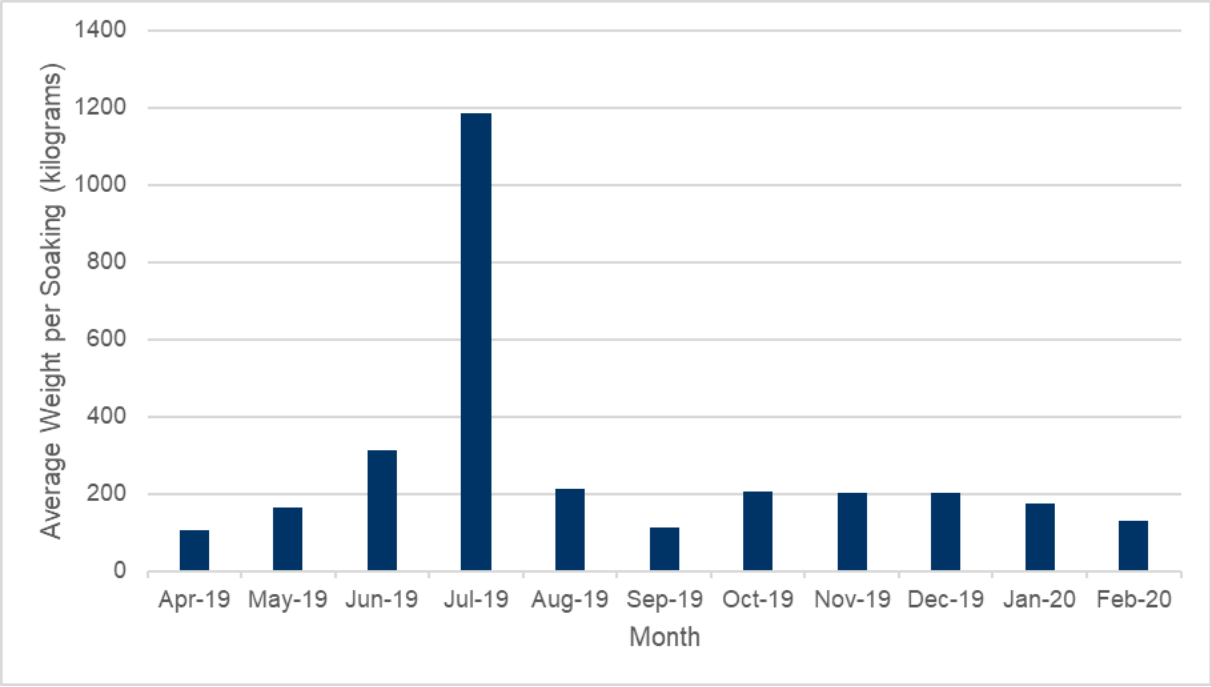

Figure N-13: Average Weight per Soaking Recorded by the Riverview Onboard Supervisor

3.4 Biometrics

The onboard supervisor measured the lengths and weights of representative fishes per each haul and the annual average lengths and weights of these fishes are shown on Figure N-14. Based on the measurements taken by the onboard supervisor, most of the fishes caught were sexually mature. In addition, there was a significant size variance of species caught with the largest being the swordfish at 71 centimeters and the smallest species was prawns at 13 centimeters. Annual average lengths of bangamary and butterfish indicate that these two species had reached sexual maturity. The annual average lengths of trout, which was the third most abundant species caught indicate that this species did not reach sexual maturity. In addition, similar to the trends observed in the data collected by the regional supervisor, all shark species recorded were juveniles of their species. All other species would be considered sexually mature.

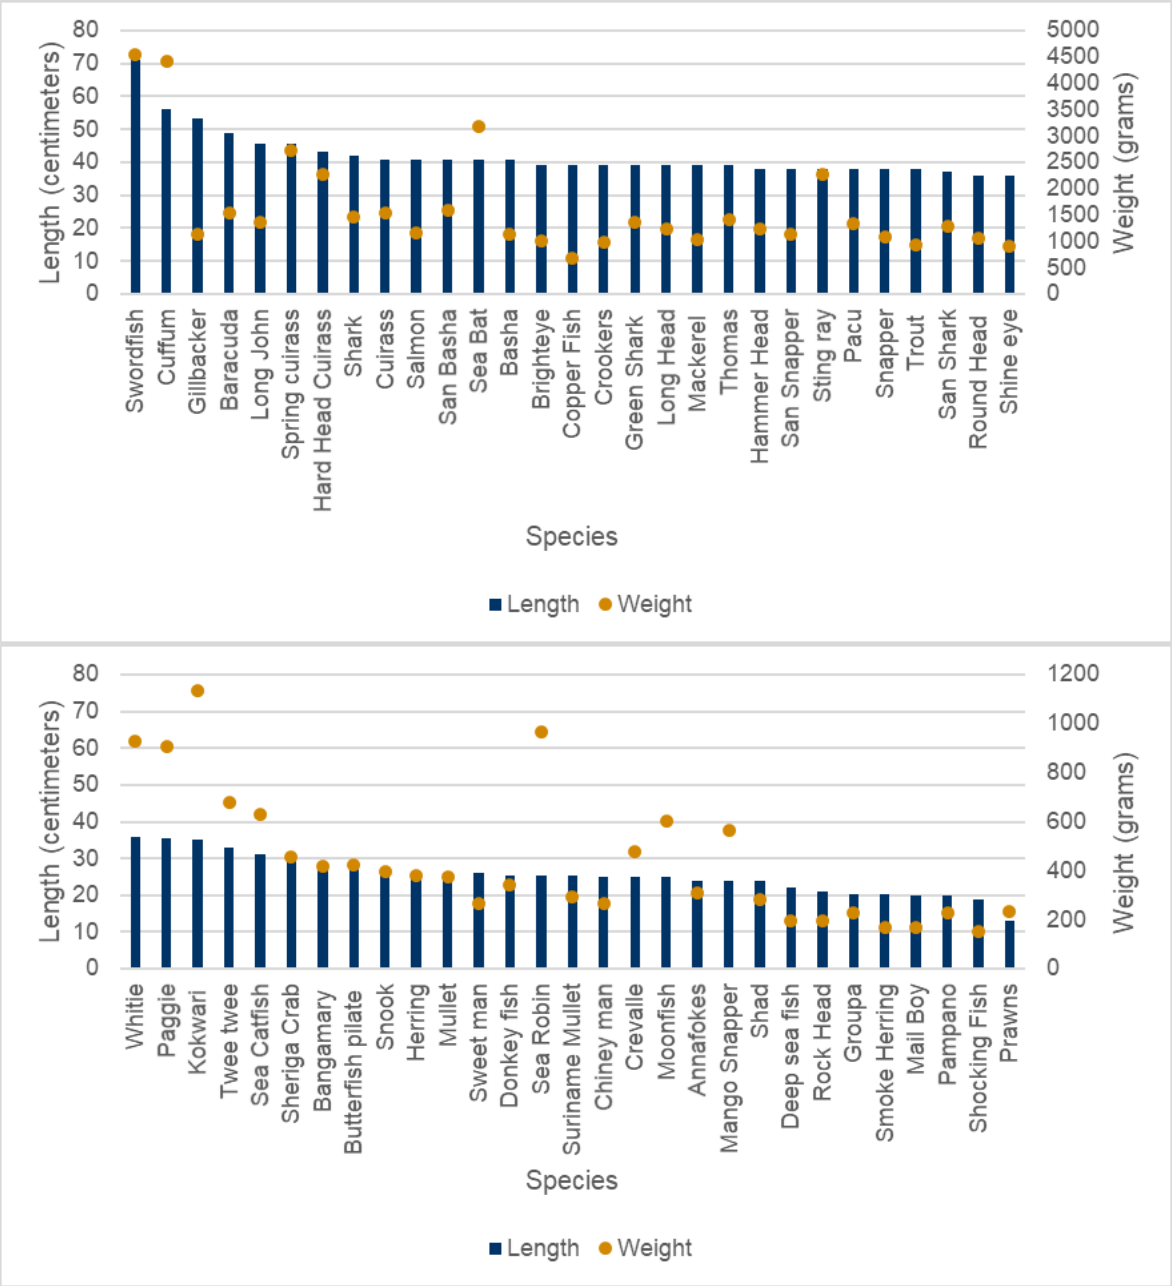

Figure N-14: Average Length and Weight of Fishes Caught by the Riverview Onboard Supervisor

The monthly average lengths and weights of the four most abundant species caught are presented on Figure N-15. Although the mesh size of the drift seine used by the onboard supervisor was smaller than drift seines used at other landing sites, such as Hampton Court and Charity (Region 2), the average annual lengths of the most abundant species caught was greater than 30 centimeters indicating that these species have matured. This is in direct contrast to the hauls at landing sites from Chinese seines. At landing sites in Lima (Region 2), Zeeburg and Windsor Forest (Region 3), and Ogle (Region 4), most of the fishes are smaller than 30 centimeters due to the mesh size.

Trout achieved peak sizes in May 2019 while the largest, bangamary, butterfish, and sea catfish, were caught in June 2019. This may be attributed to these species coming closer to shore to spawn at these times. The onboard supervisor could not confirm whether larger fishes caught over the July to September spawning period were spawning females as fish are not gutted prior to sale. The sizes of these fishes subsequently declined, which is consistent with trends observed at other landing sites of smaller fishes being recorded following the spawning season. However, the sharp decline in sizes in August 2019 was unusual and the likely reason for this dip is unknown. During the hard season from October 2019 to February 2020, the length of species plateaued and remained fairly constant for bangamary, butterfish, and sea catfish; this was anticipated. It is also important to note that the size of sea catfish did not increase in February 2020 as was observed in hauls from onboard supervisors at La Grange and Windsor Forest in Region 3.

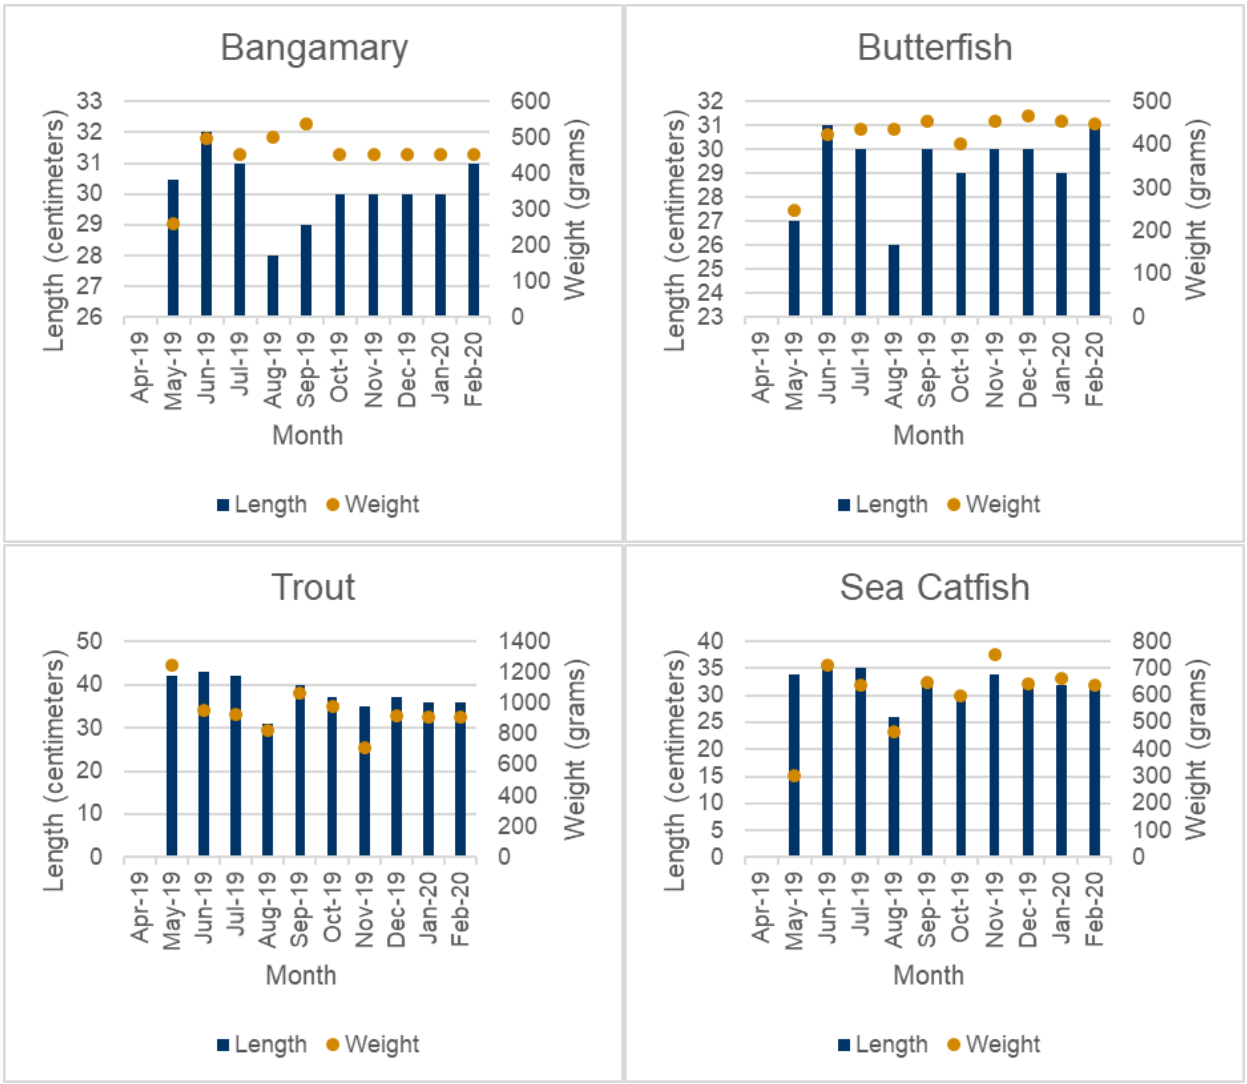

Figure N-15: Monthly Average Length and Weight of Most Caught Species at the Riverview Landing Site

4 QA/QC DATA

The first QA/QC exercise at this landing site was intended to determine whether the data collected by the supervisors was representative of fishing activities at this landing site. As a result, the study coordinator decided to assess the haul of a selected vessel at the landing site. The selected vessel was representative of vessels and fishing practices at the landing site to enable haul comparisons with data collected by the regional supervisor for a typical fishing trip. Further, this would also allow for comparisons with the haul recorded by the onboard supervisor. The vessel assessed used a bangamary seine and was powered by a 40 hp outboard engine. The vessel was returning from a 3-day fishing trip where the seine was soaked five times along the Mahaica coast.

As seen on Figure N-16, bangamary was the most abundant species caught and was the largest proportion of the haul by a wide margin. This aligns with the haul composition typically expected from a vessel using a bangamary seine and follows the haul composition of data collected by the onboard supervisor from the Riverview (Unity, Mahaica) landing site. Based on the findings of the QA/QC exercise, the decision was made not to renew the volunteer agreement with the regional supervisor at the landing site because of significant discrepancies which were revealed in the data. These discrepancies were:

- Analysis of the data recorded by the supervisor for July 2019 revealed almost equal proportions of butterfish, trout, and bangamary in total hauls of bangamary vessels. Typically, it is expected that the most abundant species caught by bangamary vessels is bangamary. The second and third most abundant species caught are typically butterfish and trout. At the time of the QA/QC assessment, catch compositions recorded by the onboard supervisor at this landing site who also operates a bangamary vessel demonstrated the expected trends. In addition, data collected for bangamary vessels by the regional supervisor at the Mahaicony landing site in Region 5 also demonstrated these expected trends. These vessels all use proximate fishing grounds and such a significant divergence in catch composition is unlikely.
- Further analysis of data submitted by the regional supervisor revealed that photos and biometric data were only collected on 8 days for the month of July but data sheets were submitted for 20 discrete days.
- Based on these analyses, the PFS team visited the landing site on August 23, 2019 to observe vessel landing. The supervisor was not present at the site to record haul data or take biometric measurements. However, data sheets were completed for these two dates by the regional supervisor.
- Finally, the PFS team conducted a QA/QC exercise on September 25, 2019 and the data collected further proved the data provided by the regional supervisor were not valid because it did not correspond to total hauls and catch composition per haul. See Sections 4.4.2 and 7.4.1 for further details of trends observed.

In October 2019, a new regional supervisor commenced data collection for this landing site. On the other hand, the haul composition and biometric measurements from the selected vessel showed a consistent trend with the data collected by the onboard supervisor (Figure N-16). The main difference between the assessed vessel and the data collected by the onboard supervisor was the species diversity. However, it is likely that more species of fishes were caught by the vessel assessed, but were not considered commercially viable and disposed as bycatch before the vessel returned to the landing site.

The study coordinator adopted a similar methodology for the second QA/QC exercise conducted in January 2020 at this landing site. The vessel assessed used a bangamary seine and had spent 2 days at sea during which time the seine was soaked twice. The vessel had a total haul of 114 kilograms (251 pounds), which was significantly lower than the average weight of hauls from the onboard supervisor of 177 kilograms (390 pounds). However, the vessel assessed during the QA/QC exercise did not catch

trout, which would have increased the weight significantly. The fisherfolk operating the QA/QC vessel also indicated that hauls were consistently low during this season.

The pricing of the haul was also consistent with the data collected by the regional supervisor. For example, bangamary prices recorded by the regional supervisor were $220 GYD per kilogram ($1 USD) while the prices from the QA/QC vessel were $264 GYD per kilogram ($1.3 USD). Similarly, the prices recorded by the regional supervisor per kilogram of butterfish were $45 GYD ($0.2 USD) higher than the prices at which hauls were sold from the QA/QC vessel. The bangamary and butterfish measured during the QA/QC exercise were 31 centimeters for both species compared to the average lengths of 30 and 29 centimeters, respectively, recorded by the regional supervisor at the landing site, as shown on Figure N-17.

The study coordinator also observed the completion of the data forms and measurements of biometrics by the onboard supervisor, and was satisfied that the data collection methods followed guidance provided thereby ensuring the accuracy and reliability of the data. Overall, the study coordinator was satisfied that the regional supervisor and the onboard supervisor were accurately recording the commercial species caught and following guidance in taking biometric measurements.

APPENDIX O OGLE (REGION 4)

1 LANDING SITE OVERVIEW

The Ogle landing site is one of the largest landing sites in Region 4 for vessels using Chinese seines. Fisherfolk estimate that approximately 30 vessels use this landing site, all of which are outfitted with outboard cruisers of 15 hp. All vessels use Chinese seine with mesh sizes of 2.5 to 10 centimeters (1 to 4 inches). Fisherfolk travel to the Chinese seine "pens" approximately 3 to 10 kilometers offshore from Ogle to the mouth of the Demerara River. Fishing occurs at depths of 5 to 7 meters. Fishing trips typically last for 4 to 6 hours. The main expenses are fuel and ice that is used to store the catch for sale; the fishing activities cost $3,000 GYD ($14 USD) per trip.

Fisherfolk interviewed at the landing site indicated that species caught at this site are characterized as mixed fishes comprising bangamary, basher, cuirass, sea catfish, and shrimp. During peak fishing seasons, catch averages 100 kilograms (220 pounds) of mixed fish and shrimp. Fish can retail for $140 GYD ($0.6 USD) per kilogram and is generally sold to trucks at the landing site or other vendors.

Fishing with Chinese seines typically requires less effort than other types of fishing for two main reasons. First, "pens" are established relatively close to the shore and therefore less time and fuel are required to travel to and from their fishing grounds. In addition, travel to and from the pens is largely dependent on the 6-hour tidal cycles resulting in less time spent at sea than other types of fishing. Second, vessels that use Chinese seines have relatively low haul capacities and as a result, the duration of a fishing trip is usually shorter as vessels will not be able to transport hauls from multiple soakings of the seine on a single trip.

Fisherfolk indicated that the main challenge they experience at this landing site is accretion of mud in the channel that is not cleared. Significant accretion can prevent fisherfolk from going to sea and can also hinder easy passage back to the landing site when the vessel is laden with the haul. Some fisherfolk also indicated that seasonal variability of haul challenges the economic viability of their fishing practice.

2 ONBOARD SUPERVISOR RESULTS

2.1 Target Species and Diversity

The onboard supervisor who participated in the study used Chinese seines with mesh sizes of 2.5 to 10 centimeters (1 to 4 inches) to target seabob, which is referred to locally as corse shrimp. Fishing trips are tidal and the onboard supervisor used the high tide to travel to the "pens" to set the seine. The onboard supervisor used three pens located approximately 8 kilometers from the shore. A few Cadell lines are also used year-round and are soaked in the waters around the Chinese seine but fishes caught from these lines are not typically considered part of the commercial haul from this vessel. Instead, fishes caught by the Cadell lines are used for subsistence by the onboard supervisor and the other crew members.

Each fishing trip lasts, on average, 4 to 6 hours. The onboard supervisor's vessel has an estimated haul capacity of 500 kilograms (1,100 pounds). In general, the supervisor returns to the landing site after the seine has been hauled. The vessel has a three-member crew and is powered by a 30 hp engine. The main expense for fishing activities is fuel and ice, which is not used for preservation on fishing trips, but for storing landed hauls before they are sold. The main challenge faced by the onboard supervisor during the study period was the proliferation of sargassum that became entangled in the seines and constituted significant portions of the total haul during the February to May period.

The total weight of combined hauls from the period for which data were collected was 20,473 kilograms (45,135 pounds). Corse shrimp, the target species, accounted for 71 percent of the total haul with

14,620 kilograms (32,232 pounds) as seen on Figure O-1. Bangamary was the second most abundant species caught accounting for 12 percent of the haul with 2,520 kilograms (5,555 pounds). At the other landing sites where Chinese seines were used, the target species was white belly shrimp, although small quantities of corse shrimp were also reported. However, at the Ogle landing site where corse shrimp is the target species, white belly shrimp was the third most abundant species caught with a total haul of 995 kilograms (2,194 pounds) representing 4 percent of the total haul. The fourth and fifth most abundant species caught were netly and prawns, which are both smaller species. The onboard supervisor at the Windsor Forest landing site (Region 3) reported small quantities of netly in the hauls, but this species was not reported by any of the other Chinese seines landing sites. Hauls including prawns were also not reported by any of the landing sites where Chinese seines were the principal method used. In sum, the haul at Ogle was comprised of five crustaceans, namely corse shrimp, white belly shrimp, prawns, brown shrimp, and tiger shrimp, which is an invasive species. None of the other fisherfolk who use Chinese seines as the primary method of fishing reported such a diversity of crustacean species.

The onboard supervisor caught 31 different commercial species. This is the greatest species diversity reported by any of the fisherfolk using Chinese seines as the main method of fishing. Of this, 26 species were caught in low quantities and collectively represented less than 1 percent of the total haul. This included high- and medium-value species like snapper and trout. The onboard supervisor explained that the high diversity of species that are considered commercially viable is largely due to the primary market at which his produce is sold. In particular, the supervisor reportedly sold most of the hauls to Chinese customers who are willing to buy most of the species caught. Nonetheless, the supervisor also reported that bycatch typically comprises a significant percentage of hauls. Bycatch typically includes species such as jelly fishes, rockhead, and stingrays (endangered, rare, and threatened species). In addition, silver belt is considered commercial if it is in demand and customers are willing to buy. If there are no available markets, silver belt is considered bycatch and discarded.

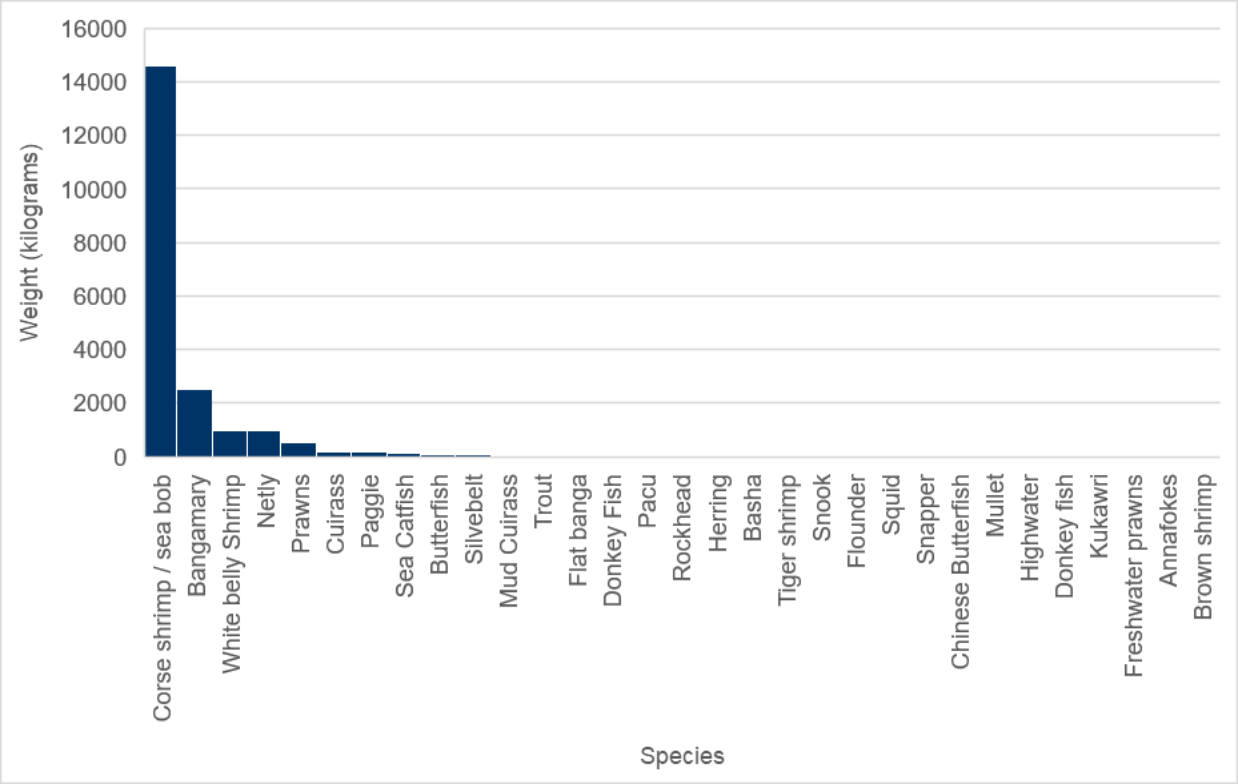

Figure O-1: Total Weight of Species Recorded by the Ogle Onboard Supervisor

2.2 Fishing Area

The onboard supervisor at this landing site has a traveling range of 151 square kilometers (see Figure O-2). The onboard supervisor fishes relatively close to shore and utilizes three clusters of pens that have been established for soaking of Chinese seines. The first cluster is just 2 kilometers offshore and the second is 4 kilometers offshore, while the third cluster is 13 kilometers offshore. These clusters are relatively close to shore, hence the effort for Chinese seine fisherfolk is relatively low. Since these structures are permanent, there is not a significant seasonal variation in fishing grounds. Unlike at the Lima and Windsor Forest landing sites, the Ogle supervisor has several pen locations at different distances offshore that the supervisor uses at different times of the year.

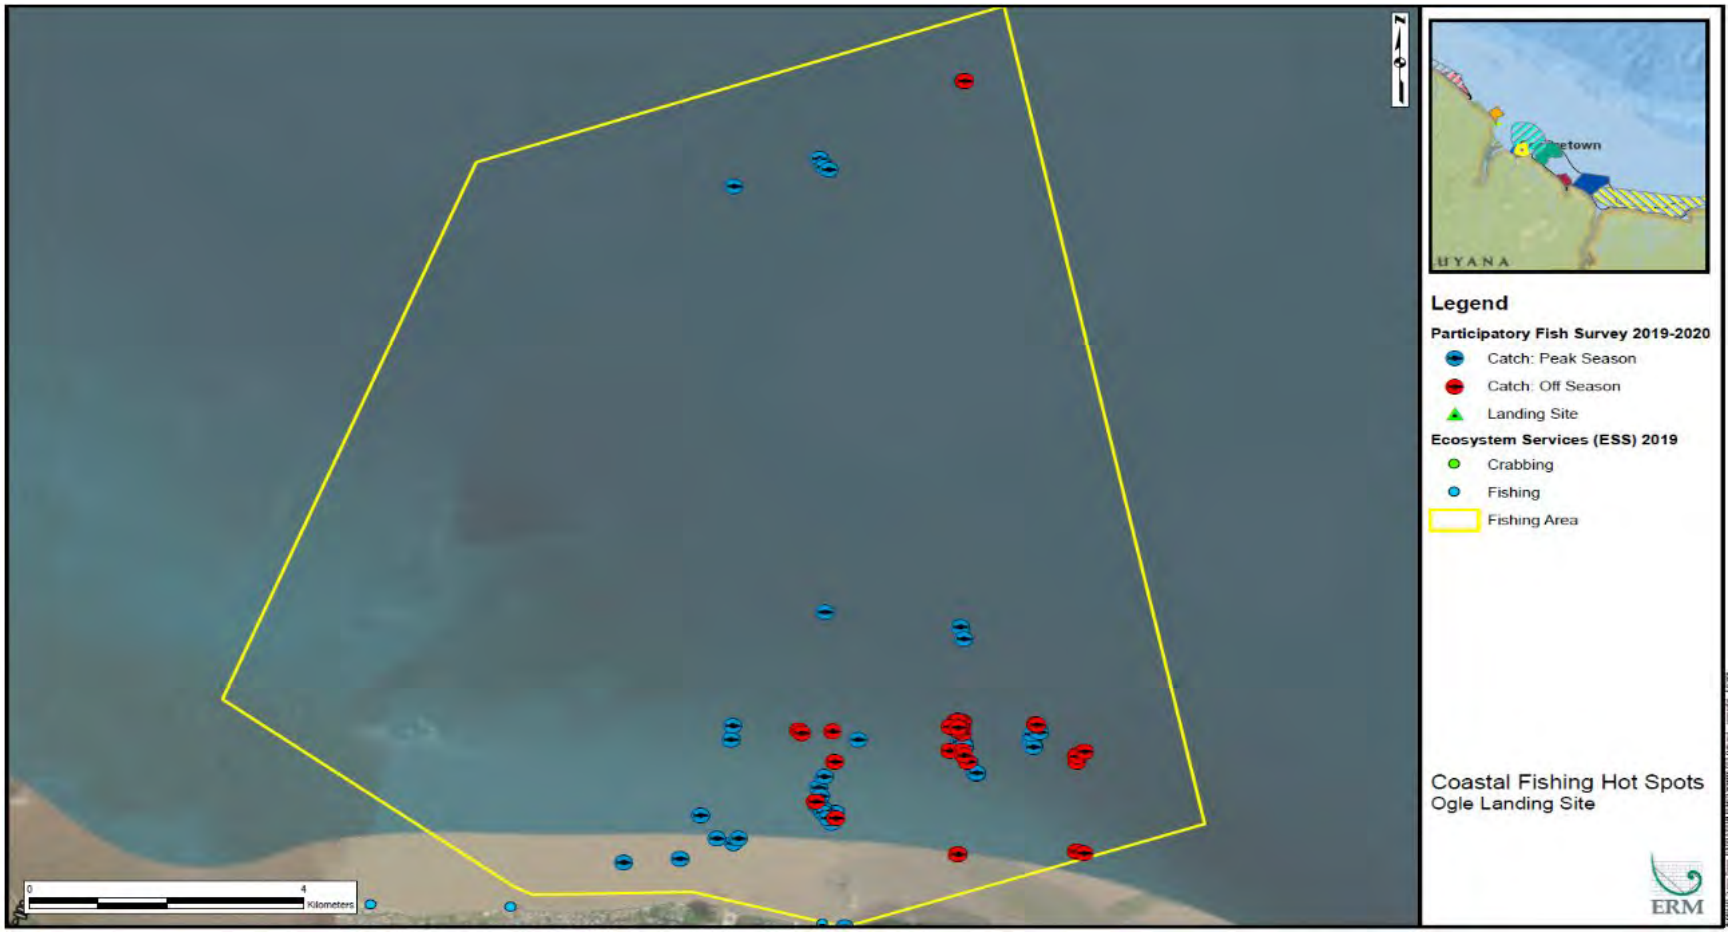

Figure O-2: Map of Fishing Area and Fishing Points Used by the Ogle Onboard Supervisor

2.3 Seasonal Productivity

Fisherfolk have varying beliefs on the most productive months for shrimping. At the Zeeburg landing site (Region 3), some fisherfolk indicated that shrimp catch generally increases during the closed trawl season, which occurs from August 16 to October 5 annually, and may allow more shrimp to come closer to the shore. Other fisherfolk indicate that the average productivity increases during the dry seasons of February to April and August to September because the waters are generally more saline compared to the wet season. Another common belief is that shrimp productivity increases during the spawning seasons of January to April and June to July (Pereira et al. 2017) when shrimp come closer to shore to spawn in the mangroves. These seasons are believed to influence effort expended by fisherfolk as well as hauls per soaking of the seine and per fishing trip.

The onboard supervisor spent an average of 93 hours at sea per month. The greatest effort was expended in November 2019 with 139 hours. Higher effort was also expended in August and December 2019 when the supervisor spent 127 and 126 hours, respectively, at fishing activity as seen on Figure O-3. By contrast, the lowest effort was expended in May and December 2019 when 60 and 62 hours were spent fishing. This is similar to the fishing practices of the onboard supervisors at the Lima (Region 2) and Windsor Forest (Region 3) landing sites where the greatest effort was expended in November 2019, and the least effort in December 2019.

As seen on Figure O-4, the highest average catch per soaking and greatest total haul were recorded in July with 433 kilograms (955 pounds), 5,197 kilograms (11,457 pounds), respectively. The second most productive months were October and November 2019 when the average catch per soaking was 145 kilograms (320 pounds) and 144 kilograms (317 pounds), respectively, which is significantly lower than the average weight of a haul per soaking in July. The total haul weights in October and November were 2,752 kilograms (6,067 pounds) and 3,018 kilograms (6,654 pounds), respectively; this is also significantly lower than the July peak.

Seasonal comparisons of effort expended by the onboard supervisor and the hauls recorded are as follows:

- In the May to September 2019 good season for fishing, the total weight of hauls was 10,632 kilograms (23,440 pounds) with 430 hours spent at sea. On average, soaking of the seine during this period yielded 145 kilograms (320 pounds).
- In April 2019, and the October 2019 to February 2020 hard season for fishing, the total weight of hauls was 9,841 kilograms (21,696 pounds) with 590 hours spent at sea. On average, soaking of the seine during this period yielded 90 kilograms (198 pounds).

Additional seasonal trends at this landing site are as follows:

- In August to October 2019, the primary dry season and the closed trawl season, total weight of hauls was 5,703 kilograms (12,573 pounds) with 351 hours spent at sea. On average, soaking of the seine during this period yielded 96 kilograms (212 pounds).
- In February 2020 and April 2019, two months of the secondary dry season, soaking of the seine during this period yielded, on average, 76 kilograms (168 pounds). Total effort and hauls were not presented since data were not retrieved for March 2020 to complete this season.
- In the January to February 2020 period and April 2019, which is the first shrimp spawning season, the total weight of hauls was 1,842 kilograms (4,060 pounds) with 213 hours spent at sea. On average, soaking of the seine during this period yielded 47 kilograms (104 pounds).

- In the June to July 2019 period, which is the second shrimp spawning season, total weight of hauls was 6,744 kilograms (14,868 pounds) with 66 hours spent at sea. On average, soaking of the seine during this period yielded 259 kilograms (571 pounds).
- In May to July 2019, which is the primary wet season, the total weight of hauls was 7,681 kilograms (16,933 pounds) with 192 hours spent at sea. On average, soaking of the seine during this period yielded 193 kilograms (425 pounds). In addition, the two most productive months, May and July, were part of this season.
- In November 2019 to January 2020 period, which is the secondary wet season, the total weight of hauls was 5,814 kilograms (12,818 pounds) with 326 hours spent at sea. On average, soaking of the seine in this period yielded 102 kilograms (225 pounds) as shown on Figure O-5.

Based on the seasonal effort and productivity presented above, the most productive season was the good season where hauls were greater although lower effort was expended. However, based on other seasonal trends examined, the most productive periods were the second spawning season and the wet seasons. The second spawning season also significantly intersects with the primary wet season. Increased productivity in the wet seasons, and as a consequence the second spawning season, were also observed by the onboard supervisors at the Lima (Region 2) and Windsor Forest (Region 3) landing sites, both of whom also used Chinese seines as the principal gear type. However, at those landing sites, the greatest effort was expended during the secondary dry season, whereas the greatest effort was expended during the primary dry season by the Ogle onboard supervisor. Due to the relatively constant level of effort expended per fishing trip, it is not likely that total effort expended per fishing trip influences productivity. Instead, total hauls are dependent upon the average haul per soaking, which also follows the trends in seasonal productivity discussed above. Additional data are needed to determine whether these trends are typical of the hauls from this supervisor.

In addition, it is of interest that July 2019 was also the most productive month at the landing sites in La Grange and Windsor Forest (Region 3) and the Riverview landing site (Region 4). At all of these landing sites, productivity sharply declined in August 2019. The onboard supervisor also indicated that these periods are not typically as productive and the reasons for this difference are not known. At the La Grange, Windsor Forest, and Riverview landing sites, productivity remained relatively low from August 2019 to February 2020. However, subsequently, all of these landing sites had a marginal uptick of total haul in October 2019 compared to September 2019. However, further data are required to enhance understanding of seasonality of fishing versus shrimping and whether fishing grounds may also play a role in determining seasonality and productivity.

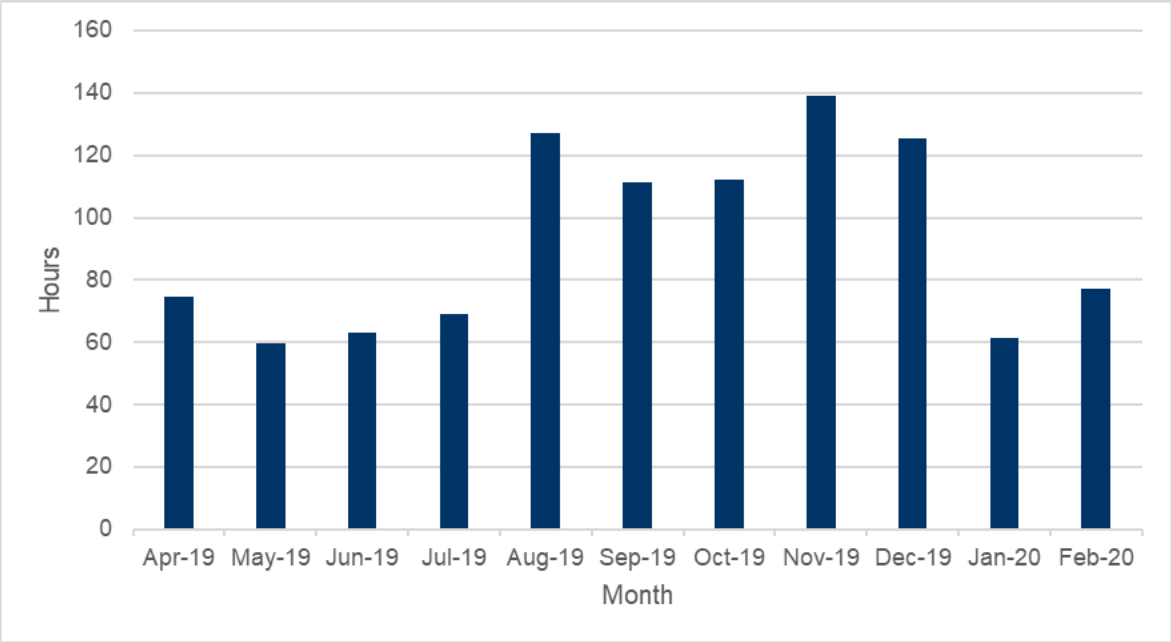

Figure O-3: Total Monthly Fishing Effort Recorded by the Ogle Onboard Supervisor

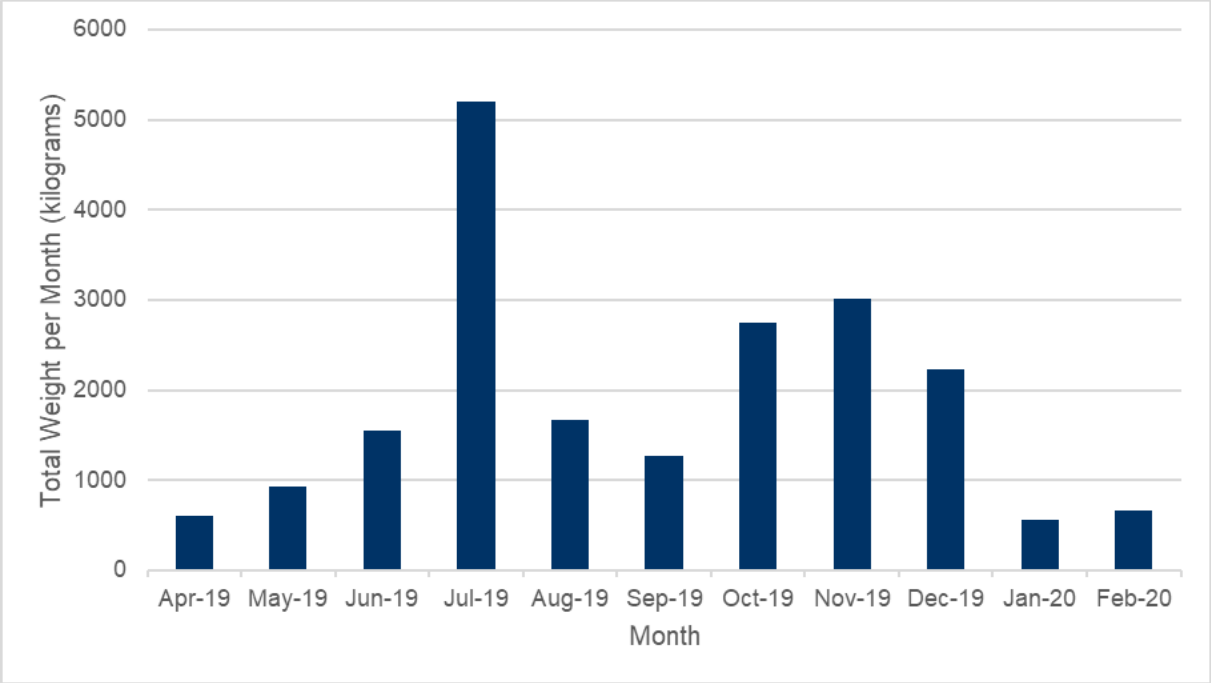

Figure O-4: Total Monthly Weight Recorded by the Ogle Onboard Supervisor

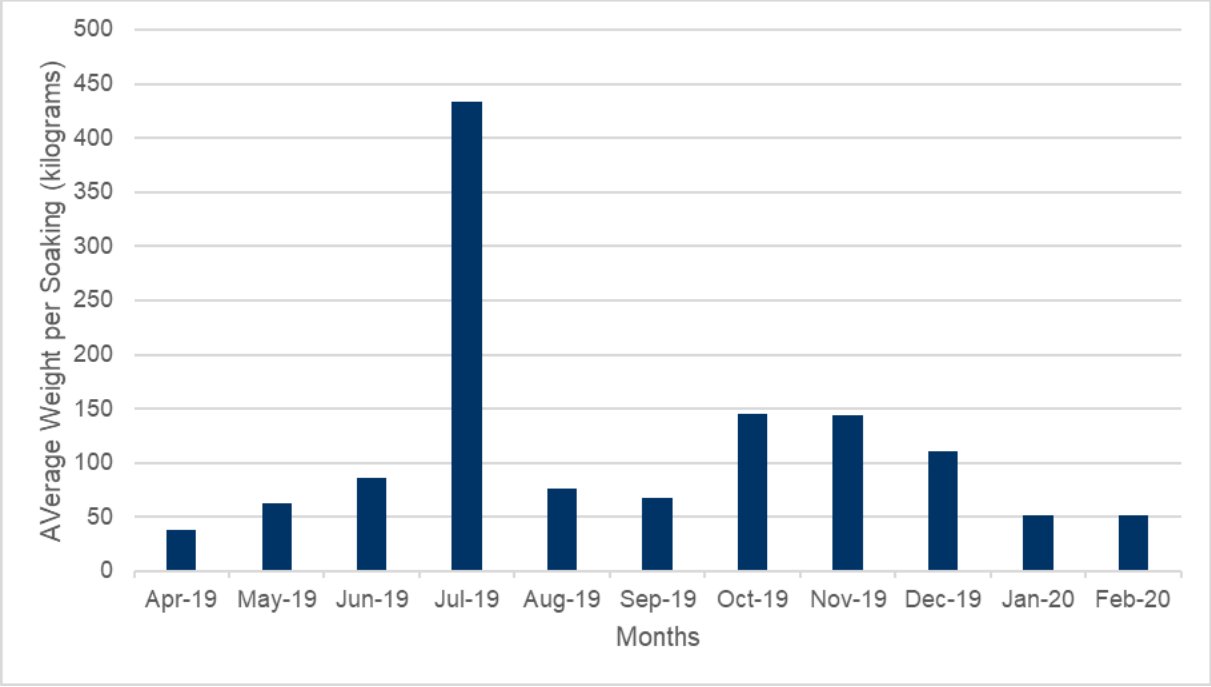

Figure O-5: and Average Weight per Soaking Recorded by the Ogle Onboard Supervisor

2.4 Biometrics

The onboard supervisor measured the average lengths and weights of representative fishes of the 47 species that were caught (see Figure O-6). However, markets were not available for some of these species and as a result they were all considered bycatch and discarded. These 16 species included electric ray, eel, blue rem sluch, butterflop, Chinese butterfish, pinto, and jellyfish. The onboard supervisor caught several species that he classified as ‘flat banga’ to represent a combination of juvenile species typically too small to be considered marketable. This label is similar to the onboard supervisor from Windsor Forest considering several species of juvenile fishes as ‘small banga’. However, based on observations by the study team, the ‘flat banga’ caught by the Ogle onboard supervisor were considerably smaller and more diverse than the ‘small banga’ caught at Windsor Forest. Expert judgement based on an external visual observation of the species called ‘flat banga’ also raised concerns that they may not have developed gonads.

In general, the commercial species caught were immature and this is directly attributed to the mesh sizes on the Chinese seines. Seines with smaller mesh sizes are expected to capture the smaller species and smaller fishes that pass through and escape seines, which have larger mesh sizes. The onboard supervisor’s commercial hauls were comprised of several smaller species that may be considered immature including netly, annafokes, mullet, and the five species of shrimp. Of the larger commercial species, trout captured at Ogle had often reached sexual maturity based on annual average lengths and weights, but species like bangamary, butterfish, cuirass, and sea catfish—for which annual average lengths and weights indicated that they had reached sexual maturity in hauls from relatively proximate landing sites (La Grange, Windsor Forest and Riverview)—were all immature at Ogle.

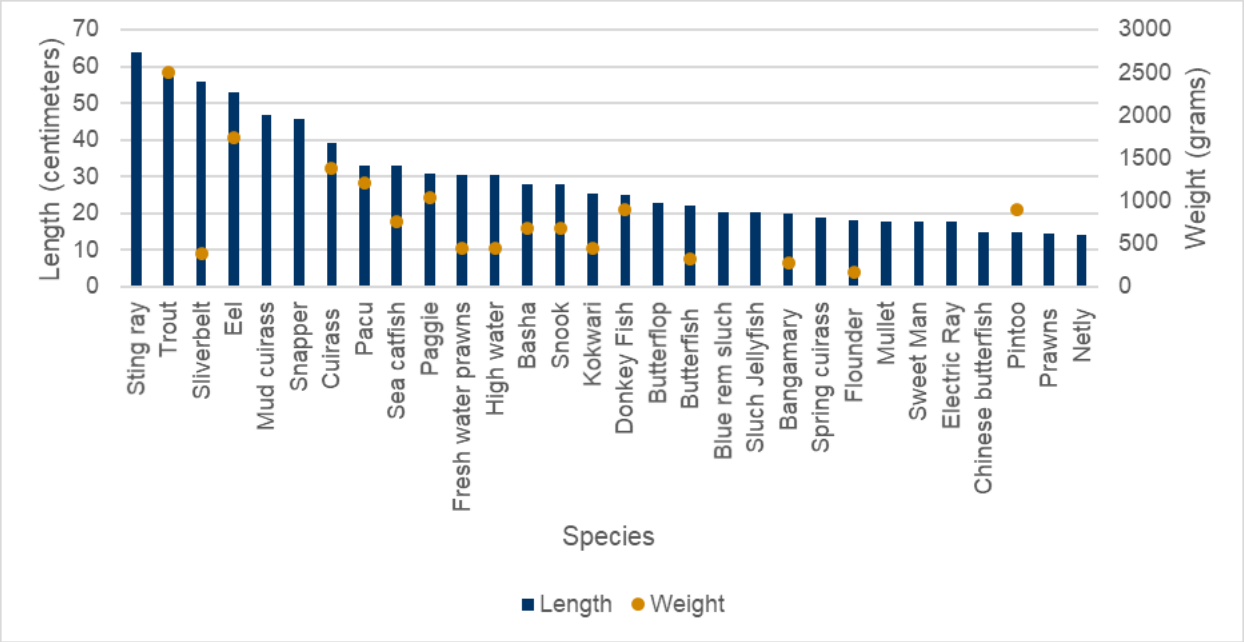

Figure O-6: Average Length and Weight of Fishes Caught by the Ogle Onboard Supervisor

The monthly average lengths and weights of the four most abundant species caught are presented on Figure O-7. Three of the four most abundant species caught were smaller and although there were monthly size variations, they were all considered mature. However, there are no clearly defined seasonal trends in the sizes of these species caught. The largest corse shrimp, the most abundant species caught, were recorded in the primary rainy season (May to July 2019) and the October to December 2019 period. These were also among the most productive periods for the onboard supervisor and the May to July period follows the first spawning season (January to April) and overlaps with the second (June to July). The October to December period also follows the closed trawl season. Additional data would be needed to determine whether these factors influence the sizes of fishes caught. However, it should be noted that similar trends in size variations were observed for white belly shrimp for which the largest was caught in May 2019, but sizes were constant for all other months in which measurements were taken.

The size of netly was relatively stable throughout the study period, but the smallest individuals were caught in January and February 2020. This is similar to corse shrimp where the smallest were also reported in January and February 2020. Bangamary was the only species of the four most abundant species that showed major variation in biometric data. The largest bangamary were caught in October 2019 while the smallest were caught in April, July and August 2019, and February 2020. These size variations are not consistent with observations at any of the proximate landing sites. Despite the variations in size, none of the measured bangamary had reached sexual maturity.

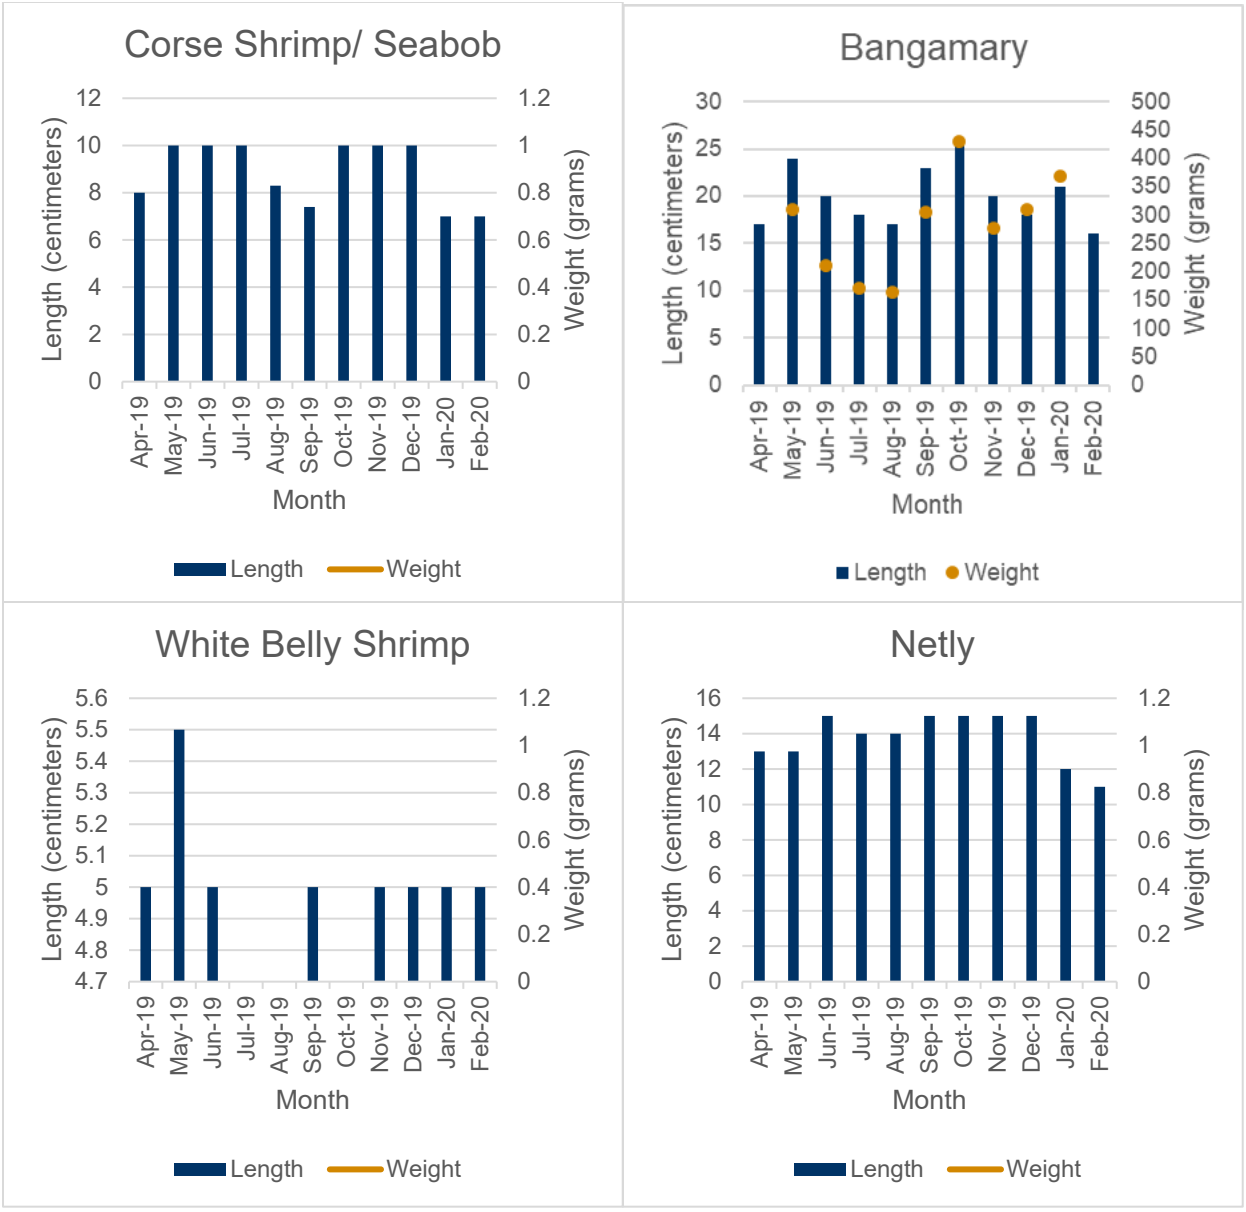

Figure O-7: Average Lengths and Weights of the Most Abundant Species Caught [4]

3 QA/QC DATA

During the QA/QC exercise, a GoPro camera was installed on the vessel belonging to the onboard supervisor from the Ogle landing site. Several key observations were made from the video monitoring conducted on 23 September 2019:

- Bycatch is discarded overboard while the vessel is still at sea. This practice has led to the development of a commensal relationship between the fisherfolk and seabirds such as pelicans, seagulls, and frigate birds that feed on the discarded bycatch. These birds flock to the vessel when the seines are pulled up expecting food. This relationship may exist with other scavenging species

[4] Weights of individual Corse Shrimp/Seabob, White Belly Shrimp, and Netly are too low to be measured with the scales used by the field team.

including marine scavengers. Cranes also flocked to the boat when it came inshore to clean all the scraped shrimp that remained.

- The bycatch was comprised significantly of silver belt and this is consistent with the data collected by the onboard supervisor.
- The onboard supervisor also practices line fishing while the seines are being soaked. This is for recreational purposes and catches are for subsistence use. Hauls from these lines are not reported by the supervisor as a part of the commercial catch per trip.

The onboard supervisor indicated that the trip recorded was not productive as the haul of commercially viable species was smaller than expected. Indeed, the July to September period is considered “slow” for shrimping, the haul from the trip was smaller than other fishing trips conducted by the supervisor over the reporting period and also had less species diversity (see Figure O-8). However, the biometric measurements were consistent with data previously collected and a significant number of fishes were juvenile (see Figure O-9). In addition, as previously discussed for other sites, several different species were caught and categorized as “flat banga” although at this site it was comprised mainly of juvenile bangamary. Overall, the study team was satisfied that the onboard supervisor was accurately recording the commercial species caught and following the guidance provided in taking biometric measurements.

The second QA/QC exercise was not conducted in January 2020 due to inactivity at the site during the visit. The team revisited the site in February 2020 and collected data on a haul brought to shore by the supervisor. Average total weight recorded by the supervisor in the month of February was the second lowest during the recorded period at 51 kilograms (112 pounds). The haul assessed during the QA/QC exercise was even lower at 40 kilograms (88 pounds). The majority of the haul was comprised of the corse shrimp/seabob. This corresponded with overall trends recorded by the supervisor. The diversity of the haul also included all the major species recorded by the supervisor.

The biometric data collected during the QA/QC had some small variances. For example, the average length of bangamary measured by the supervisor in February 2020 was 16 centimeters whereas a representative fish in the QA/QC haul was 19 centimeters. Corse shrimp/seabob measured 7 centimeters during the QA/QC exercise and 7.5 centimeters was the average length of measurements taken by the onboard supervisor. Netly measured 13.5 and 11 centimeters while the white belly shrimp measured 3 and 5 centimeters from the data collected during the QA/QC exercise and the average lengths measured by the onboard supervisor, respectively. Overall, the study team was satisfied that the data reported by the onboard supervisor was within an acceptable range of accuracy and following the guidance provided in taking biometric measurements.

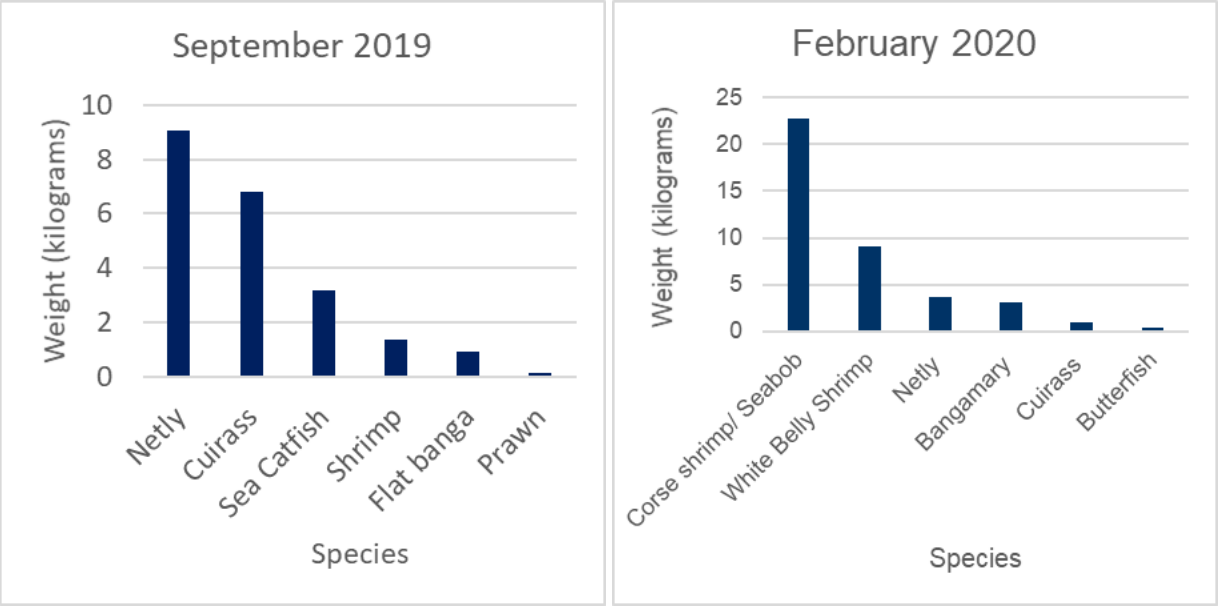

Figure O-8: Catch Composition of Commercially Viable Species during the QA/QC Exercises

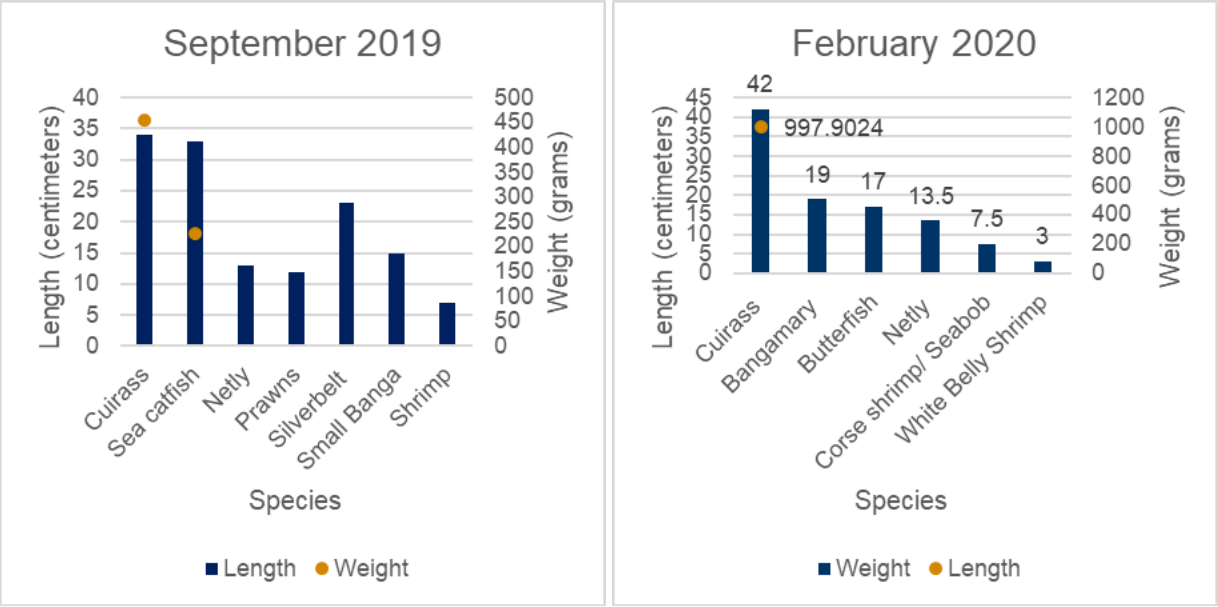

Figure O-9: Lengths and Weights of Fishes Measured during the QA/QC Exercises

APPENDIX P MAHAICONY BRIDGE (REGION 5)

1 LANDING SITE OVERVIEW

The landing site at Mahaicony Bridge is a medium-sized landing site in Region 5. Fisherfolk estimate that approximately 15 outboard cruisers operate at this landing site all of which have engines of 40 hp or greater. Most of the vessels use drift seines with mesh sizes of 6.4 centimeters (2.5 inches) to target bangamary. Bangamary is also the target species of most of the fisherfolk at the Riverview landing site (Region 4), but the mesh sizes of the drift seines are slightly larger at 7 centimeters (2.75 inches). A few vessels at the Mahaicony Bridge landing site also use drift seines with mesh sizes of 10 to 20 centimeters (4 to 8 inches), but data were not collected for these vessels. Given the similarities of fishing practices by fisherfolk at the Mahaicony Bridge and Riverview (Region 4) landing sites, fisherfolk frequently interchange where their vessels are landed for a variety of factors, including that some of the fisherfolk who utilize the Riverview landing site as their primary landing site reside in Mahaicony and vice versa. These fisherfolk have sometimes expressed a preference for landing their vessels closer to their homes. Fisherfolk indicated that the main challenge to their fishing activities are conflicts with trawler vessels while at sea, which would sail over seines causing destruction of the seines, a loss of catch, and expenses for seine mending. Their main expense is fuel.

Vessels at this landing site fish primarily along the coast of Region 5 and many fisherfolk prefer to fish at the mouth of the Mahaicony River. Fishing trips last for 1 to 3 days. Depending on the season, fisherfolk travel to preferred fishing grounds approximately 10 to 29 kilometers offshore at depths of 13 to 22 meters. Seines are soaked for 3 to 10 hours and are typically soaked more than once per fishing trip by all fisherfolk using this landing site. It may be assumed that lower species diversity of landed hauls at this site in comparison to Riverview (Region 4) may be a decision by fisherfolk to optimize the effort expended by ensuring that only fishes for which there are guaranteed markets are stored on board and transported to the landing site.

2 REGIONAL SUPERVIORS RESULTS

One regional supervisor participated in the study and the results contained within this section are provided by him over the course of the study period.

2.1 Effort and Haul

Based on the data collected by the regional supervisor, a total of 20 different species of fishes were caught with a total weight of 118,702 kilograms (261,693 pounds). Bangamary represented 76 percent of the total hauls at the landing site with a total haul of 89,692 kilograms (197,737 pounds) as seen on Figure P-1. The second and third most abundant species caught were butterfish and trout with total weights of 14,752 kilograms and 5,942 kilograms (32,522 pounds and 13,100 pounds), respectively. These represented 12 and 5 percent of the total weight of fishes caught at this landing site. Collectively, these three species accounted for approximately 93 percent of the total haul at this landing site. Hauls comprised of these three species was expected as data were collected only from the “bangamary seine.” In addition, these three species were also observed at the Riverview landing site (Region 4) because that data pool was predominantly representative of hauls from bangamary seines. The fourth most abundant species caught at this landing site was basha. However, with a total haul weight of 2,201 kilograms (4,852 pounds), it was caught in significantly lower quantities than bangamary, butterfish, and trout. Of the 20 species reported, 11 were caught in relatively low quantities of 500 kilograms (1,102.3 pounds) or lower including high-value species like snapper and red snapper.

Over the period April 2019 to February 2020, a fishing trip lasted for 28 hours on average. The following trends were observed (Figure P-2):

- The months with the lowest average effort were April 2019 and February 2020 when fishing trips lasted for 18 hours and 22 hours respectively. These months are typically considered as part of the hard season for artisanal fisherfolk. However, it should be noted that data collection at this landing site started on April 27, 2019 and consequently, the average monthly effort was calculated based on a comparatively small data pool.
- Fishing trips that lasted on average 25 to 30 hours occurred in August to November 2019, and in January 2020.
- Fishing trips lasting for more than 30 hours occurred in May to July and December 2019.

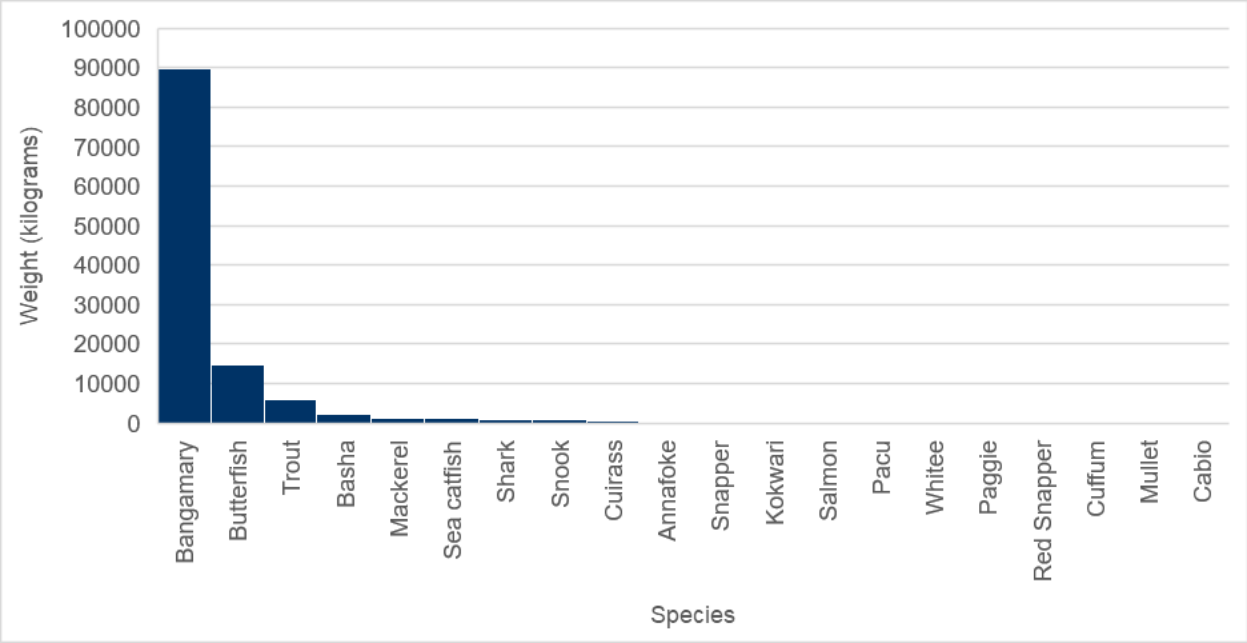

Figure P-1: Total Weight of Species Caught at the Mahaicony Bridge Landing Site

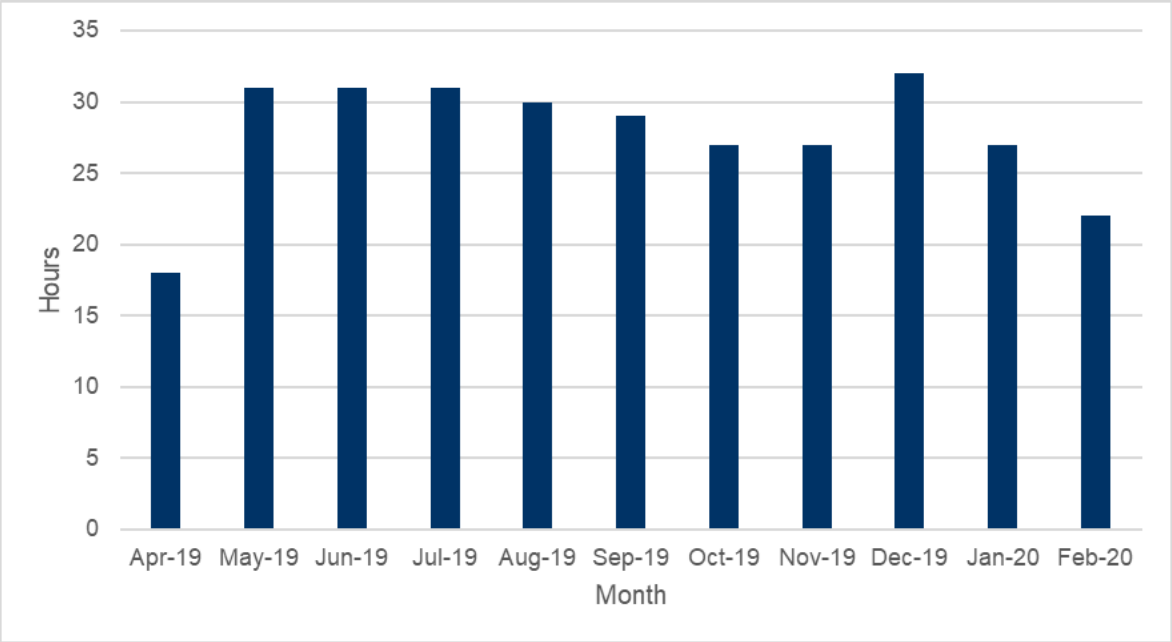

Figure P-2: Average Monthly Fishing Effort at the Mahaicony Bridge Landing Site

2.2 Target Species and Diversity

Species diversity was significantly lower than was reported at the Riverview landing site (Region 4) where 54 different species of fishes were recorded. This stark difference in species diversity may be principally attributed to what fisherfolk deem commercial species based on the markets available at each of these landing sites. The Riverview and Mahaicony Bridge landing sites are relatively proximate and fisherfolk tend to share preferred fishing grounds. As such, more species than were reported are likely caught in the seines by the fisherfolk operating out of the Mahaicony Bridge landing site, but are released or discarded as bycatch at sea. In addition, similar to hauls from landing sites in Smith's Creek and Morahwanna (Region 1), Charity (Region 2), and Riverview (Region 4), shark was also deemed a commercial species, but was not reported by species. Given the similarity of fishing grounds shared by fisherfolk at this landing site and the Riverview landing site, it may be assumed that similar species of shark were caught by the fisherfolk. The shark species reported at the Riverview landing site were green shark, san shark, the hammerhead shark (some species of which are considered vulnerable by the IUCN), and the blacktip shark, which is an endangered, rare, and protected species. Large quantities of bycatch were not reported at this landing site and this may be attributed to the relatively large mesh sizes of the seines used.

Species diversity of hauls was observed to change seasonally (Figure P-3). These changes were related to the wet and dry seasons with more species caught in the May to July 2019 wet season followed by a dip in species diversity in the August to October 2019 dry season. Thereafter, species diversity again increased in the November 2019 to January 2020 wet season before declining once again with the dry season as observed in April 2019 and February 2020. This could be as a result of increased nutrients available at the mouth of the Mahaicony River for feeding during this period. Fishes such as paggie and pacu were caught in higher quantities during this period as the brackish zone is used by fisherfolk at these times. In addition, fisherfolk believe that increased effort is required during the "hard" season. As a result, it is likely that they ventured farther offshore to fish resulting in greater species diversity and hauls comprising fishes found more frequently offshore such as mullet.

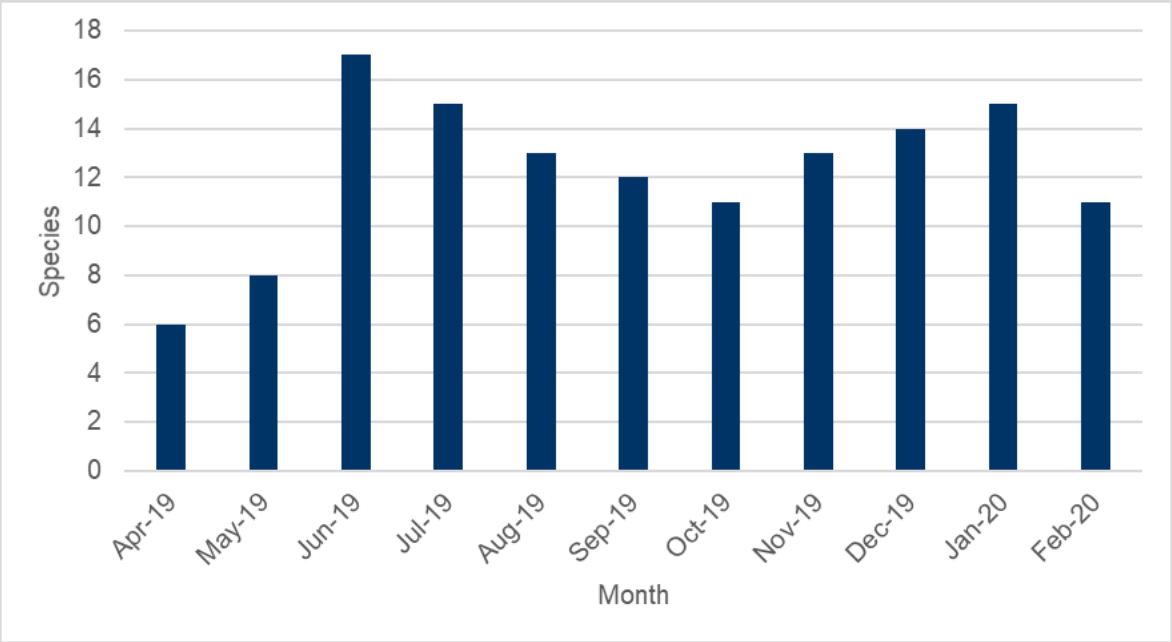

Figure P-3: Species Diversity at the Mahaicony Bridge Landing Site

2.3 Seasonal Productivity

The onboard supervisor subscribes to the commonly-held view that fishing is most productive from May to September (the so-called “good season” that peaks in July to September) and less productive from October to March (the so-called “hard season”). It is widely believed that waters are warmer and calmer during the good season, and these conditions are more conducive to fishing. These seasons are believed to influence effort expended by fisherfolk as well as hauls per soaking of the seine and per fishing trip. Figure P-4 presents the average monthly productivity of fishing trips, which was measured as the dividend of total monthly productivity by the number of fishing trips. There were variations in the average monthly productivity of the fishing trips at this lading site. Based on the good and hard seasons identified by fisherfolk, seasonal variations in average monthly productivity are as follows:

- In the April to September 2019 period, the average monthly productivity was 431 kilograms (950 pounds). Neither the most productive or least productive months were observed during this period. However, it must be noted that, like average monthly effort, the calculation of average monthly productivity for April 2019 was based on a smaller data pool.

- In the October 2019 to February 2020 period, average monthly productivity was 315 kilograms (694 pounds). Both the least and most productive months were observed during this period. The former was in January 2020 with 141 kilograms (310 pounds) and the latter in October 2019 with 622 kilograms (1371 pounds). Mahaicony Bridge and Smith’s Creek and Morahwanna (Region 1) were the only two landing sites that target fish species where the highest productivity was observed in October 2019. In addition, during October 2019 fisherfolk expended lower effort than most other months in the good season. However, it is not clear as to whether less effort was expended by design, or whether there was a greater abundance of fishes, which allowed fisherfolk to achieve optimum haul capacities more quickly.

- The most productive consecutive period at this landing site was from July to October 2019 when vessels exceeded 450 kilograms (992 pounds) every month. Average productivity was 534 kilograms

(1,177 pounds) per trip during this period. By comparison, average productivity was 289 kilograms (637 pounds) for the other months namely, April to June 2019 and November 2019 to February 2020.

By comparison, combined average productivity for the wet and dry seasons was as follows:

- In the May to July 2019 period, which is the primary wet season, average monthly haul was 451 kilograms (994 pounds).
- In the August to October 2019 period, which is the primary dry season, average monthly haul was 528 kilograms (1164 pounds).
- In the November 2019 to January 2020 period, which is the secondary wet season, average monthly haul was 259 kilograms (570 pounds).
- In February 2020 and April 2019 period, which is the secondary dry season, average monthly haul was 174 kilograms (383 pounds).

Overall, average productivity per fishing trip was on an upward trend from April to July 2019 after which it declined before peaking in October 2019. For the most part, this is consistent with fisherfolk views that the good season starts in April and continues to September. Like the Charity landing site (Region 2), seasonal productivity is not influenced by the wet and dry seasons because the difference in hauls between the wet and dry seasons is not significant. Finally, based on the data collected for this landing site in 2019, October may also be considered as part of the good season in 2019. October also the month after the end of the July to September spawning season and this may also have contributed to increased hauls during this month. Additional data are needed for this landing site to determine whether the productivity observed in October is representative of this month in other years.

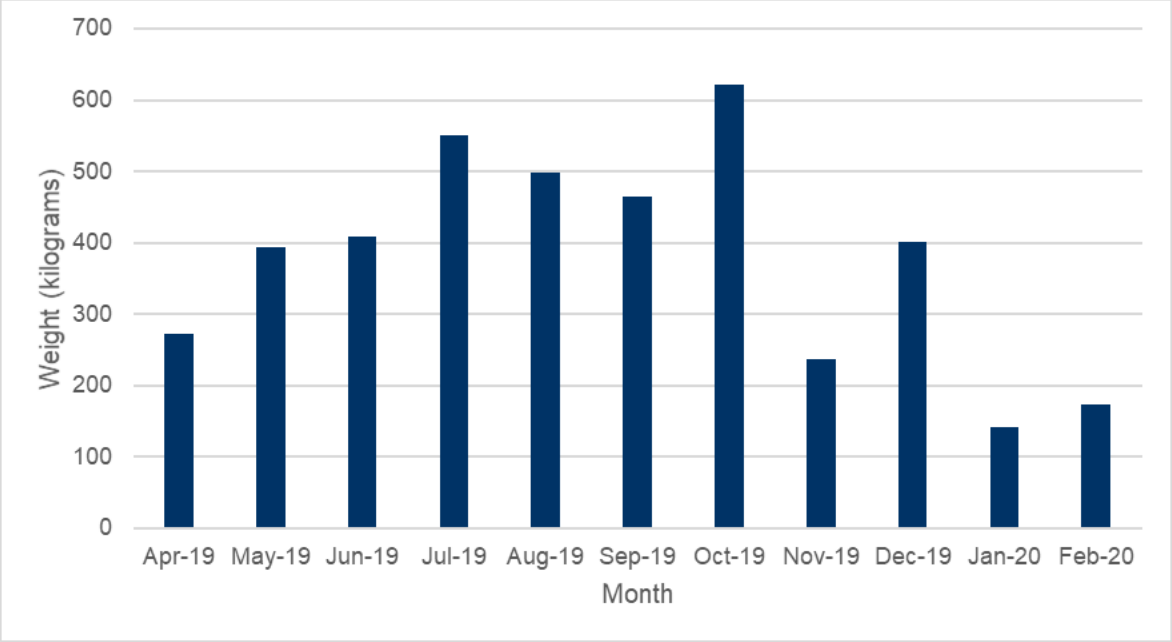

Figure P-4: Average Monthly Productivity of Fishing Trips at the at the Riverview Landing Site

2.4 Prices and Markets

Based on data collected by the regional supervisor, snapper was the highest-value fish at this landing site with annual average price of $973 GYD ($4.6 USD) per kilogram as seen on Figure P-5. Although snapper was also the highest-value fish at Charity (Region 2) and Riverview (Region 4), the annual average prices at the Mahaicony Bridge landing site were significant higher. This may be attributed to the relative scarcity of snapper in comparison to the Charity landing site and to bargaining between fisherfolk and the vendors or consumers to whom the fish is sold. Red snapper, another type of snapper reported at this landing site, was also a high-valued species. However, at prices of $551 GYD ($2.60 USD) per kilogram, it was significantly less expensive than (grey) snapper. Cabio was the second most highly valued species with an annual average price of $661 GYD ($3.20 USD). Cabio is a relatively rare fish, hence the price.

Bangamary, the target species of most fisherfolk at this landing site and the most abundant species caught, was a medium valued species with annual average prices of $225 GYD ($1 USD). The two secondary target species butterfish and trout were more highly valued with annual average prices of $331 GYD ($1.60 USD) and $592 GYD ($2.80 USD) respectively. In fact, trout was the third most expensive fish at this landing site. Although glue from trout and snapper are high-value and high demand, there is no established market for these by-products at this landing site because fishes are typically sold un-gutted. Approximately eight species were low-value at this landing site with annual average prices of less than $100 GYD ($0.48 USD) per kilogram, all of which were also infrequently caught. In total, fishes sold at this landing site were valued at $29,997,072 GYD ($144,216 USD).

Fishes landed at this site are sold to vendors who have refrigerated trucks and visit the landing site on a daily basis and typically buy large quantities of the target species bangamary, butterfish, and trout. Snapper is also sold to trucks or local vendors at the site. Vendors would both export fishes and sell in local marketplaces. Locals from Mahaicony and other neighboring communities also visit the landing site to purchase fishes directly from fisherfolk when the vessels land.

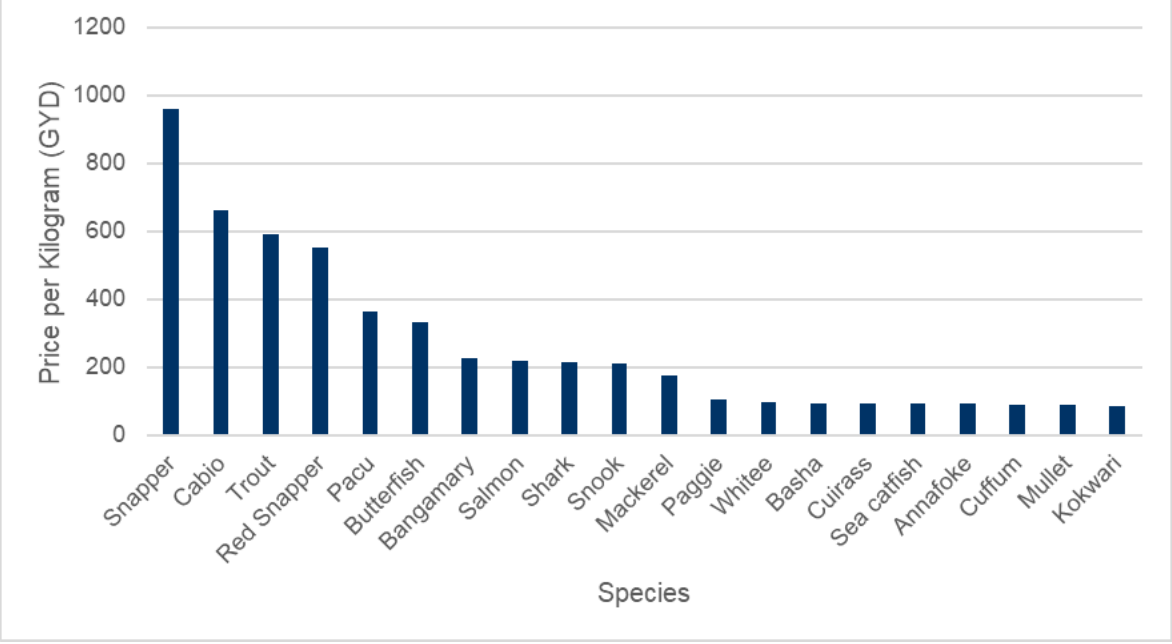

Figure P-5: Annual Average Prices per Kilogram of Fishes at the Mahaicony Bridge Landing Site

The minimum, maximum and average prices for the four most abundant species caught is shown on Figure P-6. Average prices for all four of these species was relatively stable throughout the year. However, there was a noticeable decline in the average prices from July to October 2019. This was the most productive consecutive period at this landing site and this decline could be attributed to the increase of supply. Maximum and average prices for bangamary and trout subsequently increased and peaked in December 2019 to February 2020. However, the price of trout did not increase following the price dip in July 2019 but remained at consistently low levels through to February 2020. It is likely that this was influenced by the high demand for the glue (swim bladders) from trout. Fisherfolk reported that the glue was being sold at a high price and this was an incentive to fisherfolk to increasingly target trout. As a result, there was an oversupply of this fish in the local marketplace that precipitated a decline in the price for the flesh of trout. This trend in pricing for trout was also observed at the Charity landing site (Region 2) and Riverview landing site (Region 4). Fisherfolk at the Charity landing site also indicated that oversupply of the fish as a result of the high prices of glue also contributed to the price decline.

The differences in maximum and minimum prices are attributed mainly to bargaining between fisherfolk and vendors. Some fisherfolk have indicated that they are able to bargain for better prices per kilogram when fishes are larger. This may be a contributing factor to the significant spike in maximum prices of basha in November 2019 (as seen on Figure P-6), given that average lengths and weights were higher in that month.

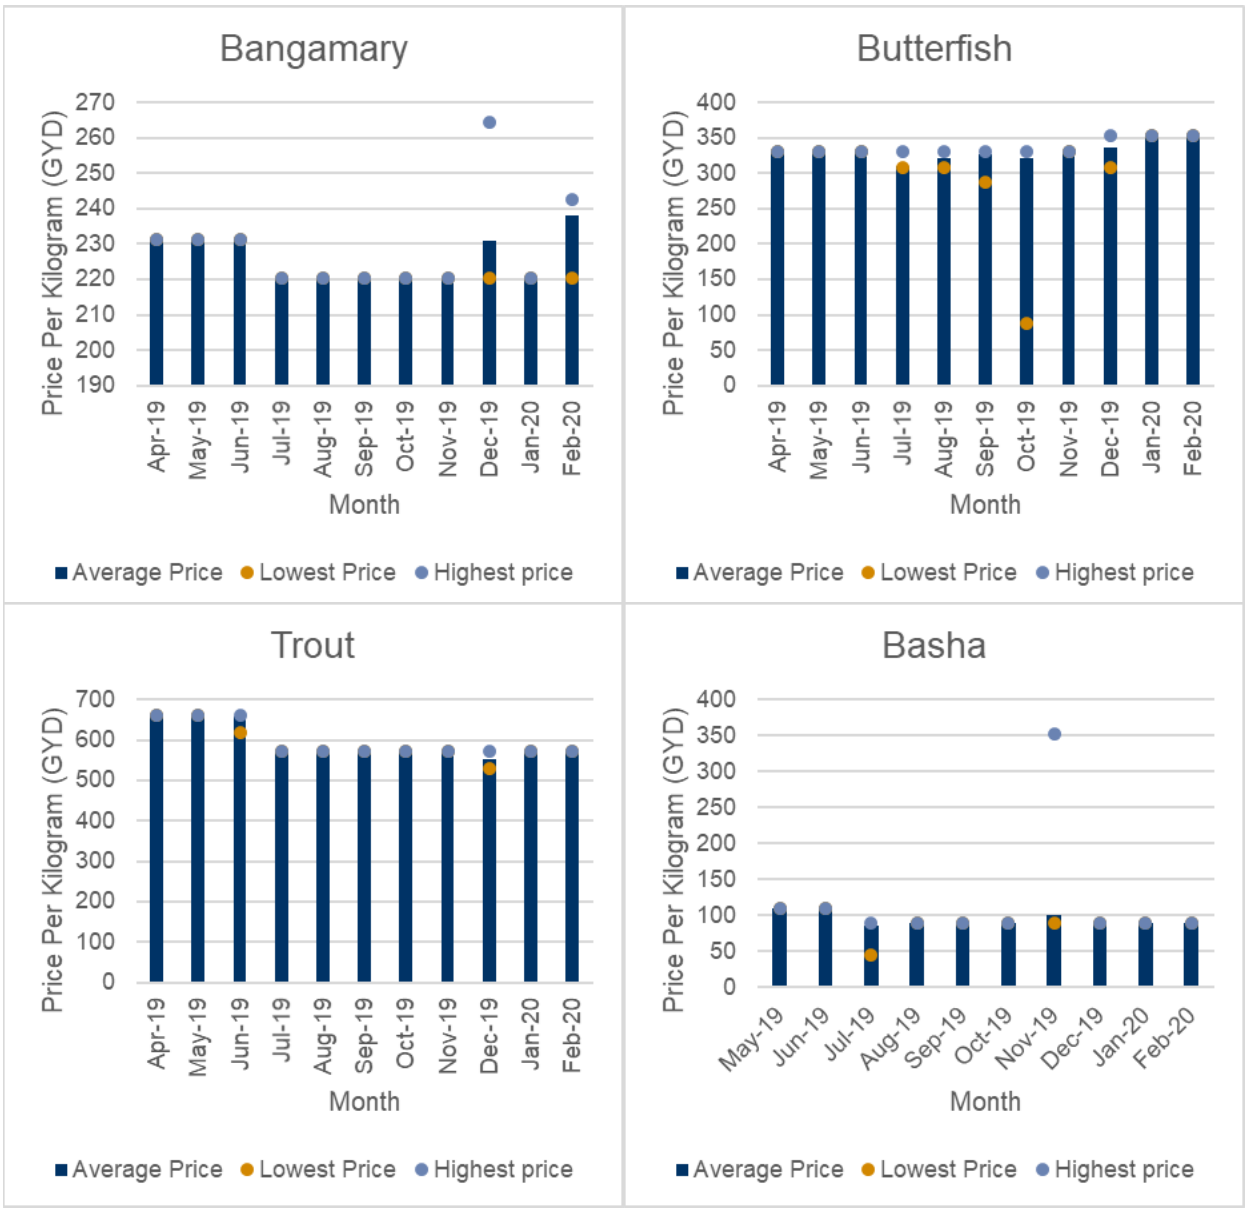

Figure P-6: Monthly Price Variations of the Four Most Abundant Species Caught

2.5 Biometrics

The regional supervisor measured the lengths and weights of fishes that were representative of hauls for which data were collected. The annual average length and weight of these fishes are shown on Figure P-7. The largest fish caught was the cuffum, which had an annual average length of 70 centimeters and annual average weight of 7,257 grams. The smallest species caught was the red snapper, which had an annual average length of 24.5 centimeter and annual average weight of 333 grams and would not be considered mature for the species. Most of the species caught at this landing site had achieved sizes of sexual maturity with the exception of the shark, which were immature.

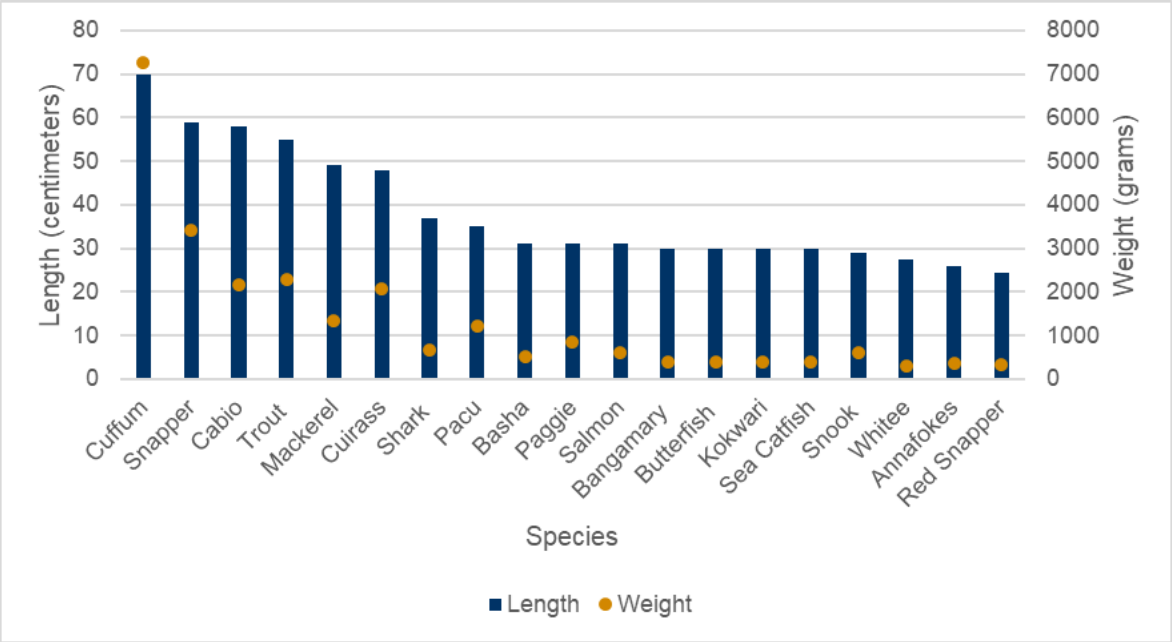

Figure P-7: Annual Average Lengths and Weights for Fishes Measured at the Mahaicony Bridge Landing Site

The supervisor did not measure the lengths and weights of fishes for the months of April, May, June, and October 2019. The monthly variations in the average lengths and weights of the four most abundant species caught for the months in which data were collected is shown on Figure P-8. The sizes of trout and butterfish peaked in August 2019 with average lengths of 60 and 31 centimeters, respectively. This adheres to the expected trends of larger fishes, typically spawning females coming closer to shore to spawn during the July to September period. However, the largest bangamary and basha were caught in December 2019. This is unusual and could be a result of the relatively small pool of data.

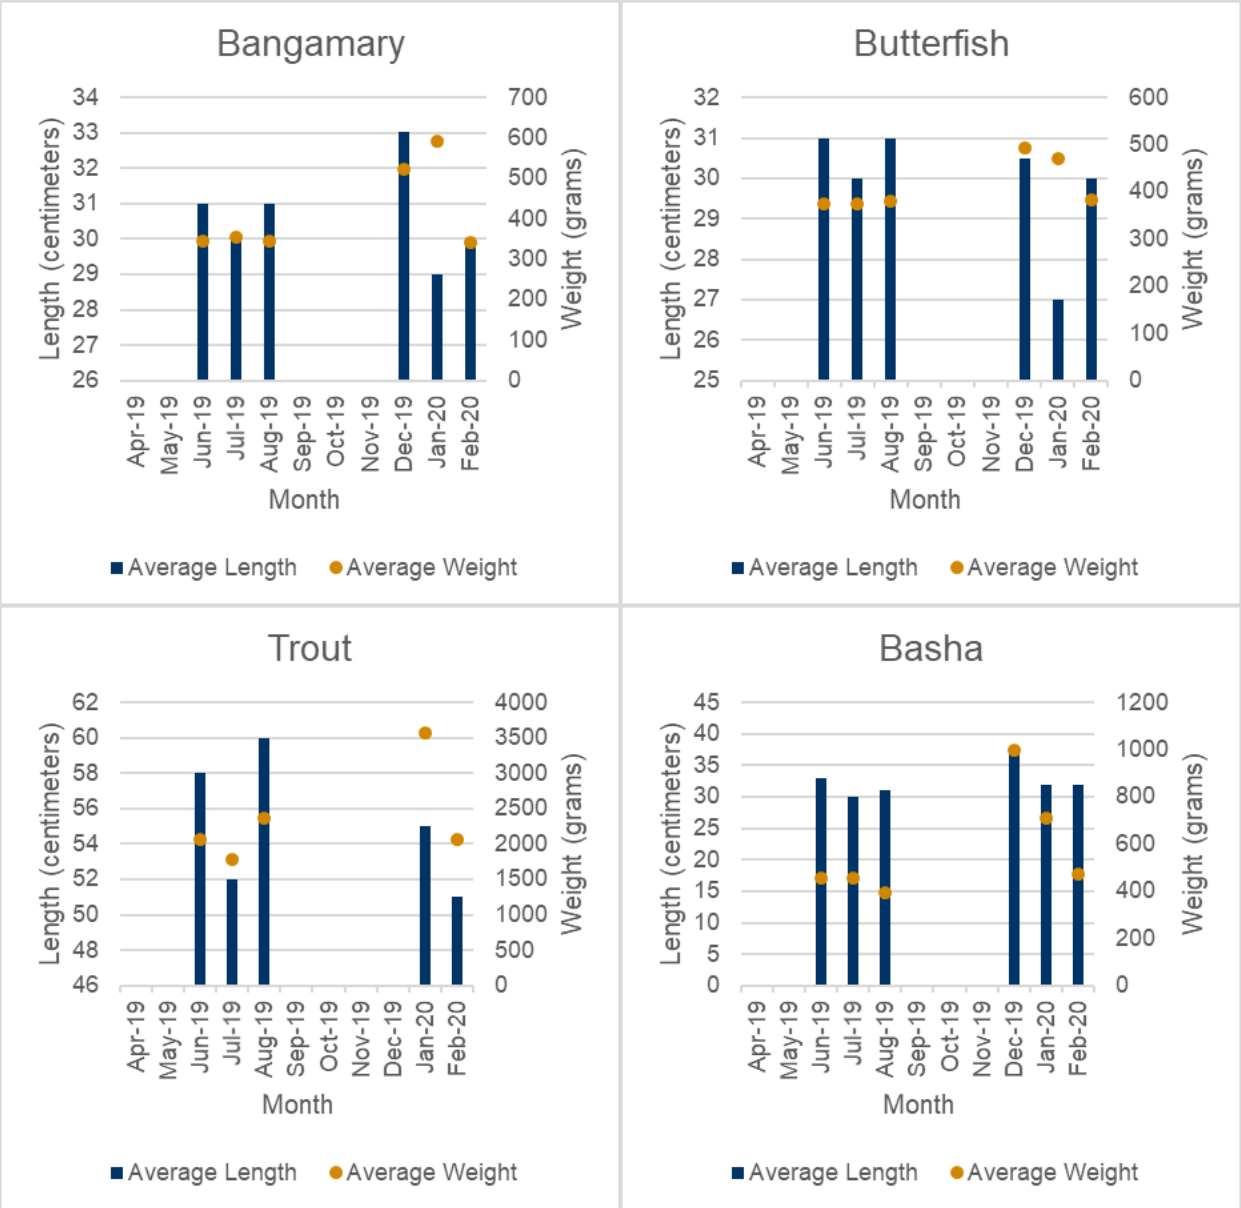

Figure P-8: Monthly Average Lengths and Weights of Most Abundant Species Caught

3 QA/QC DATA

During the first QA/QC exercise conducted in September 2019, one vessel that landed at the site was assessed. The vessel used a bangamary seine, which is typical of most vessels operating at the landing site. The vessel that was assessed had conducted a 2-day fishing trip along the coastline of Mahaicony and Abary during which time the seine was soaked three times.

The data collected from this haul generally matched the trends that were evident in the data collected by the regional supervisor. Bangamary was by far the most abundant species caught (Figure P-9). Trout was the second most abundant species caught by a slight margin, but this is not typical of bangamary vessels. Biometric measurements were also consistent with the trends reported by the regional supervisor and all

species may be considered sexually mature (Figure P-10). No bycatch was observed on the vessel by the study coordinator and likewise.

During the QA/QC exercise in January 2020, another vessel was assessed. The vessel also used a bangamary seine and had spent 2 days at sea. Total haul was 415 kilograms (914 pounds). This deviated significantly from the data recorded by the regional supervisor during January 2020 where vessels had average hauls of 141 kilograms (310 pounds). However, the QA/QC exercise was conducted relatively early in January, and it is likely that the haul was representative of trends from December 2019 when hauls averaged 400 kilograms (881 pounds). Catch composition included the three main target species of bangamary, butterfish, and trout. Bangamary represented 89 percent of the total haul, butterfish 10 percent, and trout 0.6 percent. This is similar to the proportions of these fishes in the data collected by the regional supervisor.

Prices recorded during the QA/QC exercise did not vary significantly from those recorded during this month by the supervisor. Bangamary, snook, and trout had prices of $220, $308, and $485 GYD ($1.00, $1.40, and $2.30 USD) per kilogram, respectively, during the QA/QC exercise. The recorded average prices for the species with data provided by the supervisor were $220, $353, and $573 GYD per kilogram ($1.00, $1.70, and $2.80 USD) for the bangamary, snook, and trout.

Biometric data collected during the QA/QC exercise for 30 centimeters for both bangamary and butterfish and 68 centimeters for trout. The average lengths of these species based on the data collected by the regional supervisor showed small variations during this month as bangamary measured 29 centimeters, butterfish measured 27 centimeters, and trout measured 55 centimeters. Overall, the study coordinator was satisfied that the regional supervisor was accurately recording the commercial species caught and is following the guidance provided in taking biometric measurements.

Figure P-10: Lengths and Weights of Fishes Measured during the QA/QC Exercises

APPENDIX Q BUSHLOT (REGION 5)

1 LANDING SITE OVERVIEW

Bushlot is the only landing site in Guyana at which most of the vessels are sail vessels, as fishing with sails is a dying art in the country. Fisherfolk indicated that 20 sail vessels are operational at this landing site year-round, but approximately 40 vessels use the landing site during peak fishing seasons. Although the vessels primarily use sails, some are also fitted with small outboard cruisers of 5 to 15 hp.

Fisherfolk use drift seines of 6.3 to 18 centimeters (2.5 to 7 inches) mesh size. Fisherfolk at this landing site fish about 3 to 4 kilometers off the Bush Lot beach at depths of about 1 to 4 meters. They have soak times ranging between 2 to 6 hours. Fishing trips generally cost $2,000 GYD ($10 USD).

The typical yield from a fishing trip is 27 kilograms (60 pounds). The main species caught at this site are cuffum, cuirass, bangamary, trout, and paggie that are sold as ‘mixed fish’ for $180 GYD ($0.8 USD) per kilogram. Higher valued species like snapper and trout are also caught at this landing site, and prices vary seasonally. Previously, the catch was sold to trucks that came to the site to purchase. However, the access road to the landing site is in a significantly deteriorated state, and fisherfolk now have to transport their catch to the villages for sale. Fisherfolk shared challenges of launching and landing vessels due to an accretion of mud at the landing site and also reported that rough seas were a common challenge that disrupted their fishing activities.

2 ONBOARD SUPERVISOR RESULTS

The onboard supervisor from Bushlot uses drift seines with mesh sizes of 11 centimeters (4.5 inches), 13 centimeters (5 inches), and 18 centimeters (7 inches) to target larger species of fish such as snapper and trout. The supervisor explained that the choice of gear per fishing trip is determined by recent success using either of the drift seines and hauls from other fisherfolk who land at the site. Sails are used mainly to eliminate fuel expenses; however, this method is not as efficient as using an engine and may be very time consuming. In addition, there are generally no clearly defined routes to the preferred fishing ground as vessels move with winds. As a result, the onboard supervisor also has a 15 hp engine to be used as a backup in the event of an emergency requiring quick return to shore, or if challenged by unfavorable winds. Each fishing trip lasts for approximately 12 hours and each trip has a crew of 2. Hauls from the onboard supervisor are sold to local vendors or transported by the onboard supervisor to the Rosignol landing site for sale.

Due to the accretion of mud on the landing site, the supervisor frequently relies on the high tides to leave and return to the landing site. In September 2019, the spring tides prevented the onboard supervisor from conducting the number of fishing trips that were planned for that month. The onboard supervisor also encountered significant challenges with the proliferation of sargassum during February to May. The supervisor also reported that occasionally significant quantities of seagrass are also caught in his seines.

2.1 Target Species and Diversity

The total weights of combined hauls from the onboard supervisor’s vessel over the period May 2019 to February 2020 was 4,485 kilograms (9,888 pounds), and 1,922 hours of effort was expended. Cuirass and snapper were the most abundant species caught (see Figure Q-1). Cuirass accounted for 28 percent of the total catch with 1,287 kilograms (2,837 pounds) while snapper accounted for 27 percent of the total catch with 1,211 kilograms (2,670 pounds). The third and fourth most abundant species caught were paggie and mullet, which accounted for 12 percent and 10 percent of the total haul, respectively. Overall, 22 commercial species were recorded by the onboard supervisor of which 13 were caught in relatively low quantities of 50 kilograms (110 pounds) or lower. The supervisor reported bycatch comprised of seaweed, sea bats, and stingrays (some of which are endangered, threatened, and protected species).

However, the supervisor indicated that stingrays and sea bats caught in the seines are released because it is recognized that the numbers of these species are declining in Guyana.

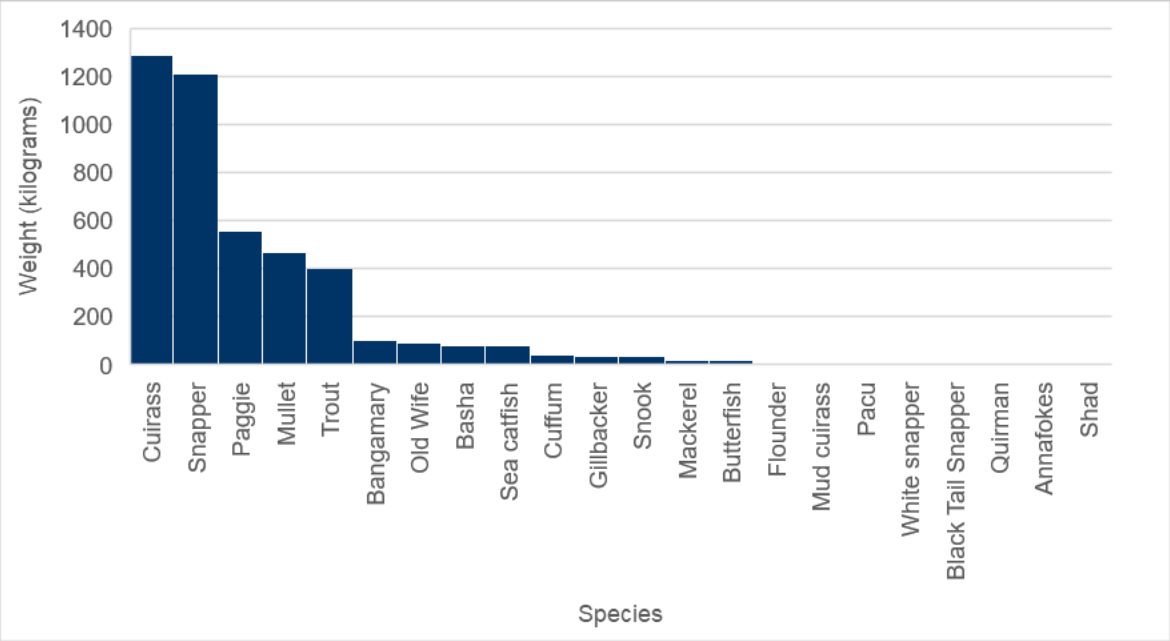

Figure Q-1: Total Weight of Species Recorded by the Bushlot Onboard Supervisor

2.2 Fishing Areas

The main fishing area used by vessels operating from Bushlot is 100 square kilometers. Overall, the onboard supervisor had a traveling range of 255 square kilometers along the west coast of the Berbice River. Figure Q-2 shows the fishing points in the seasons that were considered by the onboard supervisor as the peak/good season (May to September 2019) and off-peak/hard season (October 2019 to February 2020) at the outset of the study program. During the May to September period, the onboard supervisor consistently traveled farther offshore for fishing activities. Moreover, the farthest distance offshore was traveled for fishing in the May to September period. Specifically, the farthest distance traveled in May to September for fishing was 11.5 kilometers offshore while the farthest distance traveled for fishing in October 2019 to February 2020 was 8.5 kilometers. The closest fishing point to the shoreline was observed in September 2019, where the onboard supervisor fished just 0.25 kilometer from shore.

The onboard supervisor expended significantly greater effort in May to September, which was evidently due to fishing activities being conducted farther offshore. Several factors determined where the onboard supervisor decided to soak the seines. These factors include the amount of fishes caught in these locations before, time and distance traveling to and from fishing grounds, and the presence of other fisherfolk or fishing activities in the area. In addition, the calmer seas reported to prevail during the May to September period would have allowed longer distances to be traversed more easily by the supervisor's sailboat.

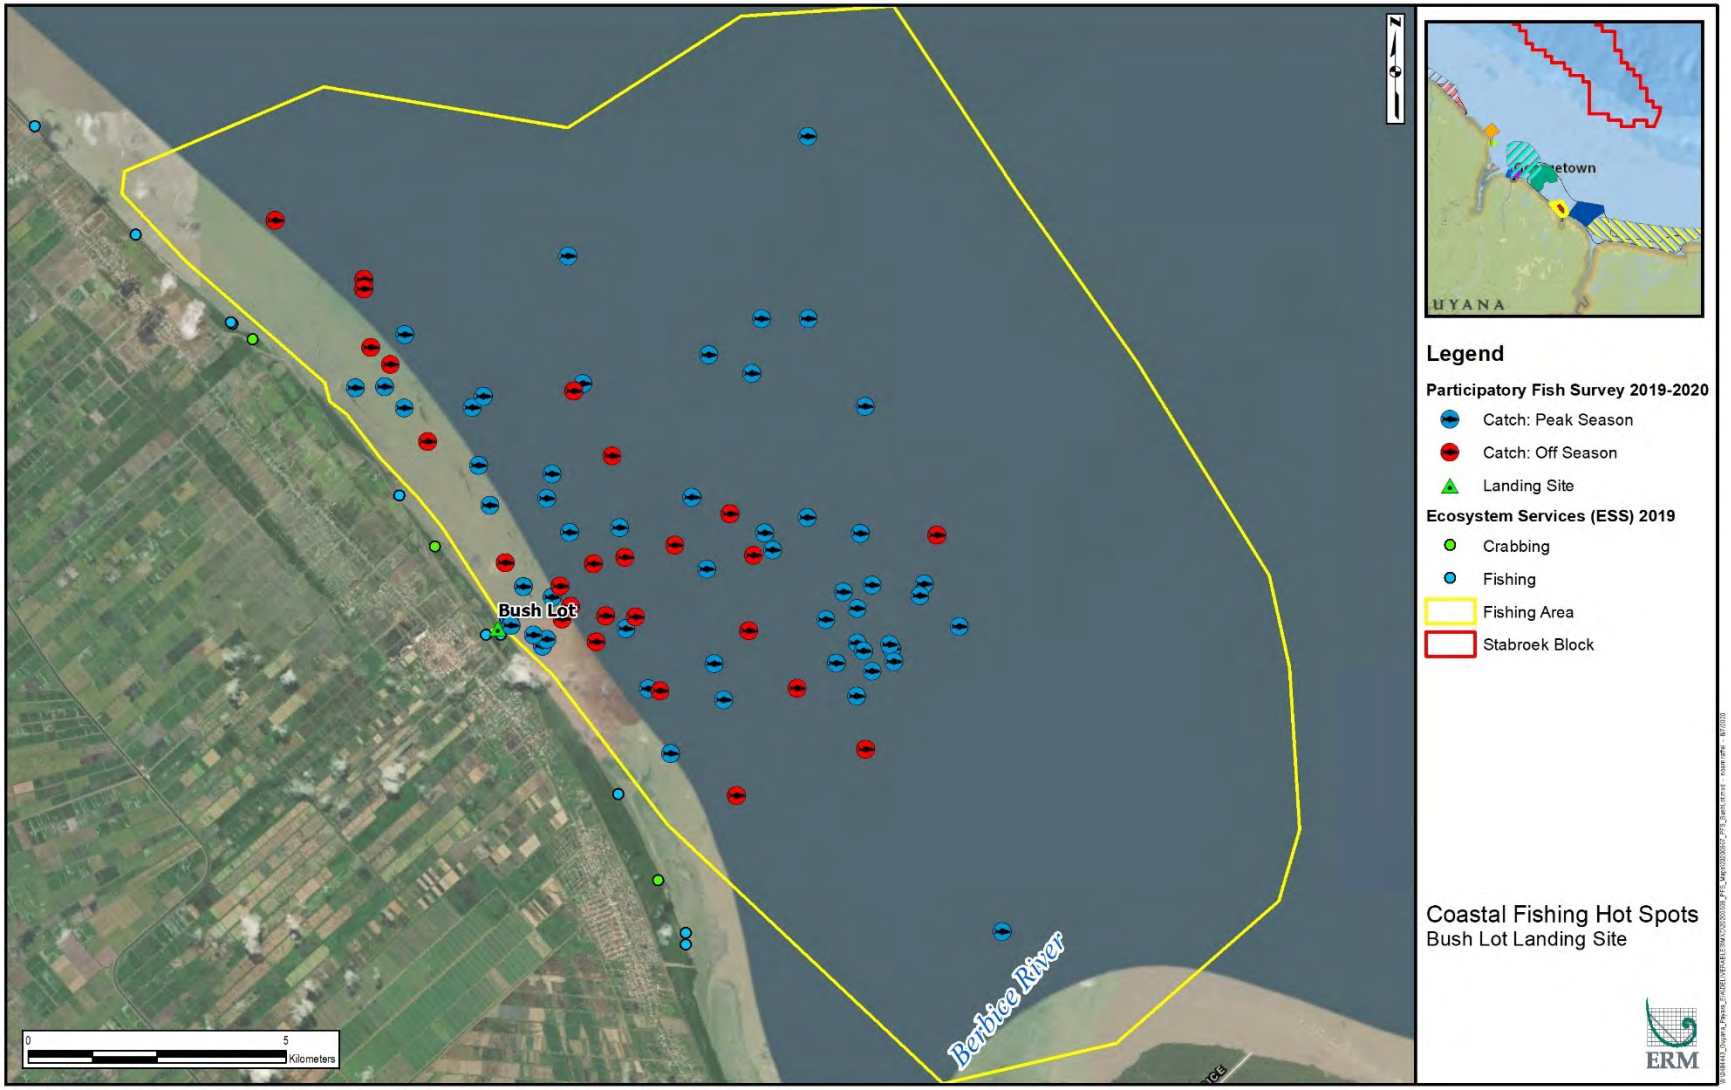

Figure Q-2: Fishing Area and Fishing Points Used by the Bushlot Onboard Supervisor

2.3 Seasonal Productivity

The onboard supervisor subscribes to the commonly-held view that fishing is most productive from May to September (the so-called “good season” that peaks in July to September) and less productive from October to March (the so-called “hard season”). It is widely believed that waters are warmer and calmer during the good season, and these conditions are more conducive to fishing. These seasons are believed to influence effort expended by fisherfolk as well as hauls per soaking of the seine and per fishing trip.

During the study period, the onboard supervisor spent an average at 192 hours per month fishing but there were variations in the effort expended per fishing trip on a monthly basis as seen on Figure Q-3. The onboard supervisor’s monthly effort peaked in July 2019 with 299 hours of fishing activity. The lowest effort was expended in September 2019 when 113.5 hours were spent fishing, but this reduced effort was due to the spring tides that prevented the supervisor from going to sea.

As seen on Figure Q-4, the greatest total hauls were recorded in November 2019 with 750 kilograms (1,653 pounds). The highest average weight of hauls per soaking was recorded in January 2020 with 40 kilograms (88 pounds) as seen on Figure Q-5. This is unusual as both of these months are part of the hard season for fishing. Moreover, the lowest average weight of hauls per soaking was in August 2019, which was expected to have been the peak month for fishing at this landing site, with 14 kilograms (31 pounds). Except for September 2019 when fishing activities were curtailed by the spring tides, the lowest total haul was observed in August 2019 with 270 kilograms (595 pounds).

Seasonal variations in effort and productivity were observed as follows:

- In the May to September 2019 good season, the total weight of hauls was 1,798 kilograms (3,964 pounds) with 1,031 hours spent at sea. On average, soaking of the seine in this period yielded 20 kilograms (44 pounds). Within this period, the average weight of hauls consistently declined over June to August. Moreover, although effort increased in July 2019, the total monthly haul declined due to the lower productivity per soaking. Productivity further declined in August 2019 to the lowest levels recorded at this landing site.

- In the October 2019 to February 2020 hard season, total weight of hauls was 2,687 kilograms (5,923 pounds) with 891 hours spent at sea. On average, soaking of the seine in this period yielded 33 kilograms (73 pounds). In particular, total hauls and average productivity per soaking were consistently high from November 2019 to February 2020. Compared to the May to September 2019 season, total hauls were greater, soakings more productive on average, and overall effort lower.

By comparison, seasonal trends in the wet and dry season were as follows:

- In August to October 2019, the primary dry season, total weight of hauls was 787 kilograms (1,735 pounds) with 551 hours spent at sea. On average, the seine yielded 17 kilograms (37 pounds) per soaking in this period.

- In May to July 2019, the primary wet season, total weight of hauls was 1,376 kilograms (3,034 pounds) with 372 hours spent at sea. On average, the seine in this period yielded 25 kilograms (55 pounds) per soaking in this period.

- In November 2019 to January 2020, the secondary wet season, total weight of hauls was 1,776 kilograms (3,915 pounds) with 524 hours spent at sea. On average, the seine yielded 36 kilograms (79 pounds) per soaking in this period.

- In February 2020, which is considered within the secondary dry season, the total weight of hauls was 546 kilograms (1204 pounds) with 176 hours spent at sea. On average, soaking of the seine in this

period yielded 34 kilograms (75 pounds). In addition, data collection at this site did not commence until May 2019 and therefore, there will be a data gap for April to complete this season.

Based on the trends seen above, there appears to have been a reversal of the good and hard seasons at this landing site. Specifically, the average weight of hauls per fishing trip was lower than 30 kilograms (66 pounds) from May to October 2019. However, productivity was consistently higher over the November 2019 to February 2020 period. The supervisor indicated that this reversal in seasonality has occurred previously and that this is the second consecutive year in which this was observed. However, the supervisor was unable to offer any reasons as to why this would have been observed. Data collected from onboard supervisors at the Albion (Region 6) and Complex 66 (Region 6) landing sites also show unseasonably high productivity over the October 2019 to February 2020 period. Additional data are needed from this landing site to determine what factors could have contributed to this reversal.

Based on the differences observed in the good and hard seasons, productivity based on climatic seasonality also changed relative to the other seasons. As a result, the average weight of hauls during the primary wet and dry seasons were significantly lower than in the secondary wet season and February 2020 (the only month of the secondary dry season for which data are available). In addition, total hauls in the primary wet and dry seasons were lower than the total hauls in the secondary wet season.

The trends in seasonal productivity may also explain why effort peaked in July 2019. Several other onboard supervisors expended peak effort in November and December 2019, the hard season, including at landing sites in Lima (Region 2), Windsor Forest (Region 3), La Grange (Region 3), Riverview (Region 4), Ogle (Region 4), Rosignol (Region 5), and Albion (Region 6). Only the onboard supervisor from the Complex 66 landing site also expended the greatest effort in July 2019. Given that productivity was declining, the onboard supervisor may have decided to expend greater effort on fishing to increase the total monthly haul and this may have been accomplished with relative ease because waters are generally calmer and more conducive to fishing. Overall, the trends observed at this landing site highlight that conventionally held beliefs about seasonality are not necessarily applicable at all times and places in Guyana.

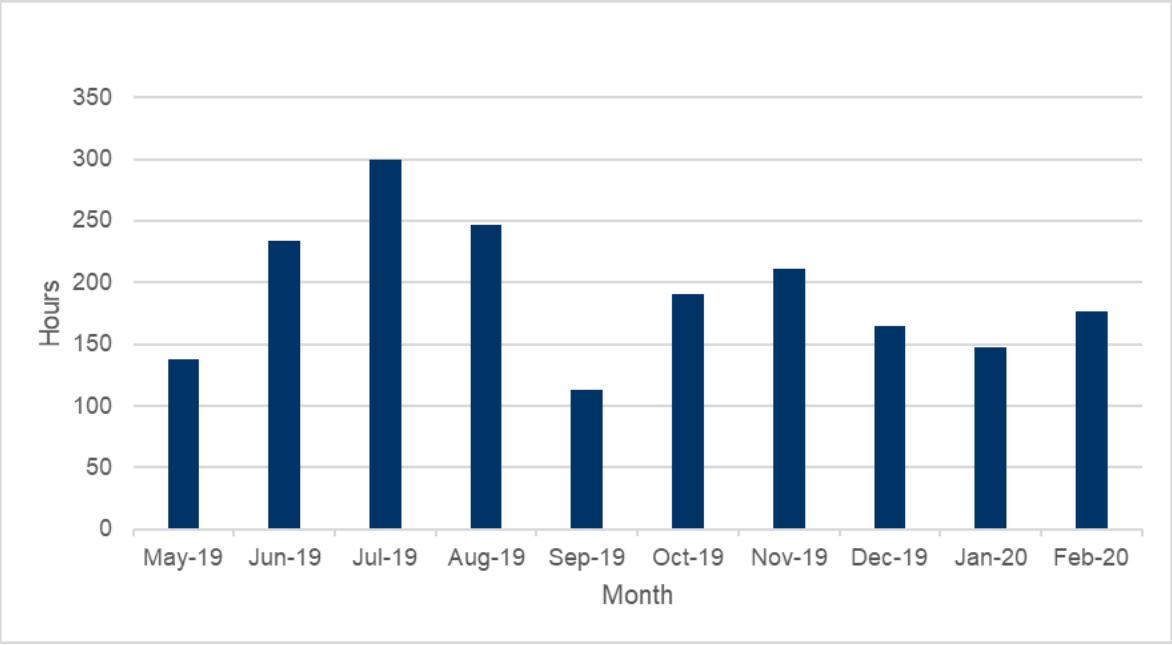

Figure Q-3: Total Monthly Fishing Effort Recorded by the Bushlot Onboard Supervisor

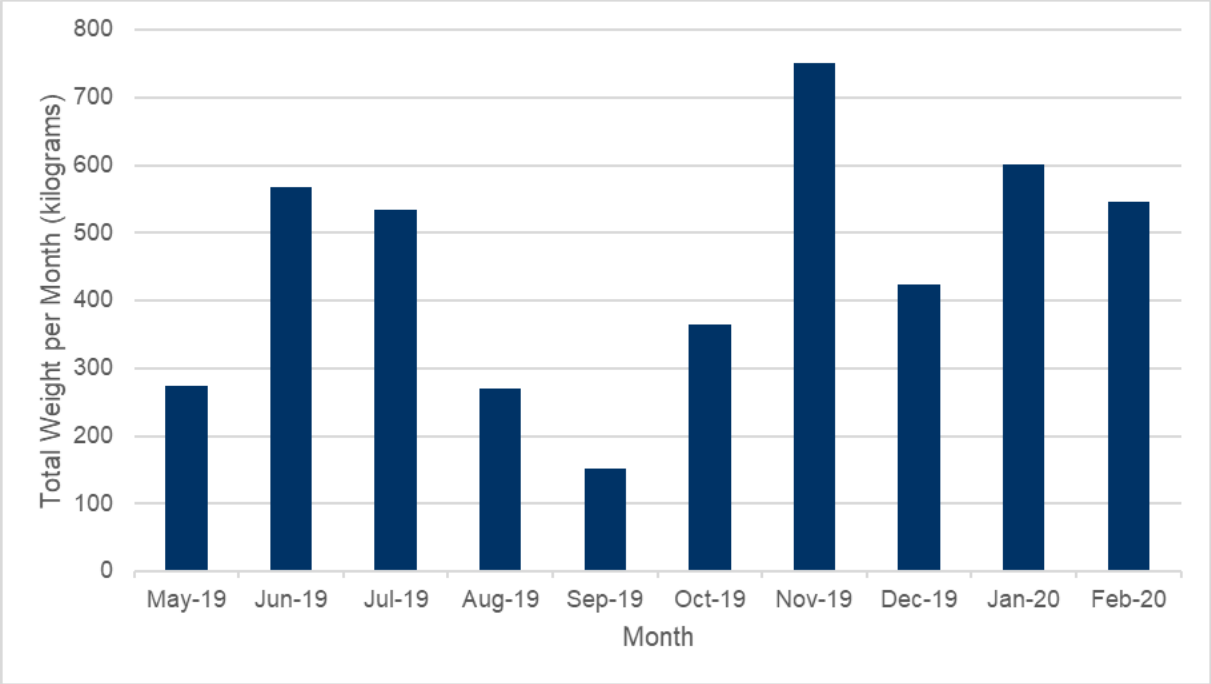

Figure Q-4: Total Monthly Weight Recorded by the Bushlot Onboard Supervisor

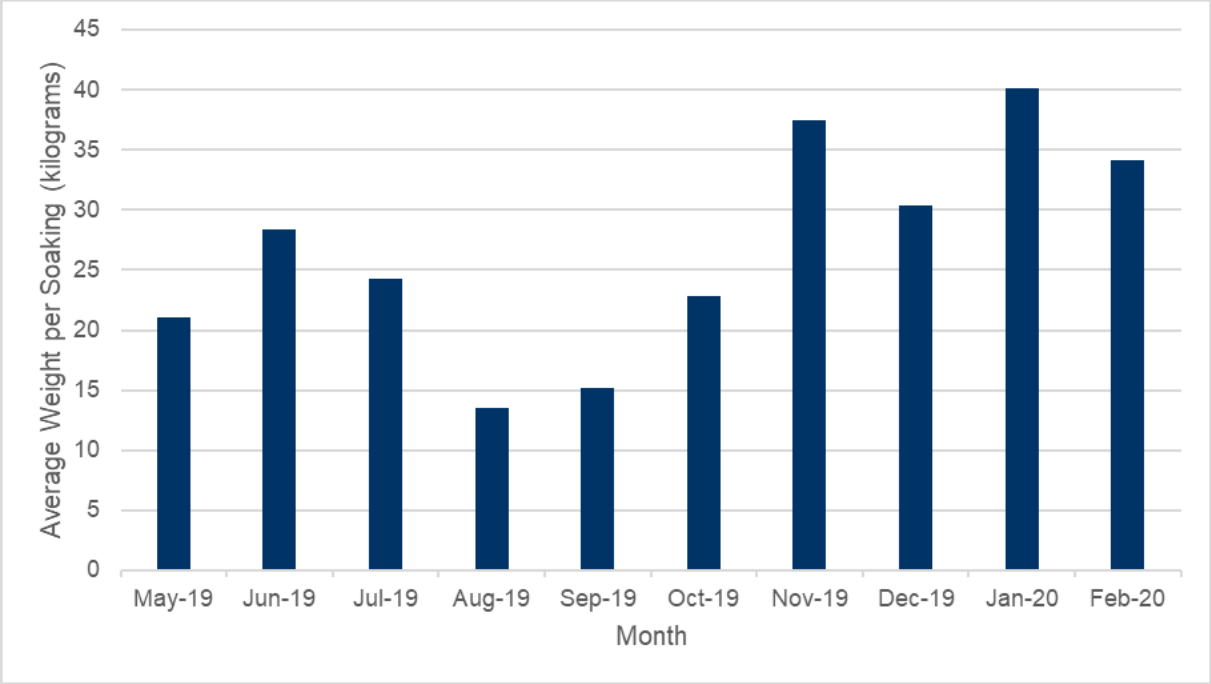

Figure Q-5: Average Weight per Soaking Recorded by the Bushlot Onboard Supervisor

2.4 Biometrics

The onboard supervisor measured the lengths and weights of representative fishes per each haul and the annual average lengths and weights of these fishes are shown on Figure Q-6. Based on the measurements taken by the onboard supervisor, most of the fishes caught were sexually mature. The two most abundant species caught were also mature with snapper reaching annual average lengths of 67 centimeters and cuirass 58 centimeters. These larger fishes were caught because the onboard supervisor used the drift seine with mesh sizes of 18 centimeters (7 inches) most frequently. However, the annual average length of bangamary was 23 centimeters indicating that hauls of this fish were mainly juveniles. This was unexpected given that the mesh sizes of the seines used by the supervisor is larger than those on the bangamary seines from which hauls typically comprise mature fish. Additional data collection by this supervisor will allow for a better understanding of how often juvenile bangamary is typically caught at Bushlot.

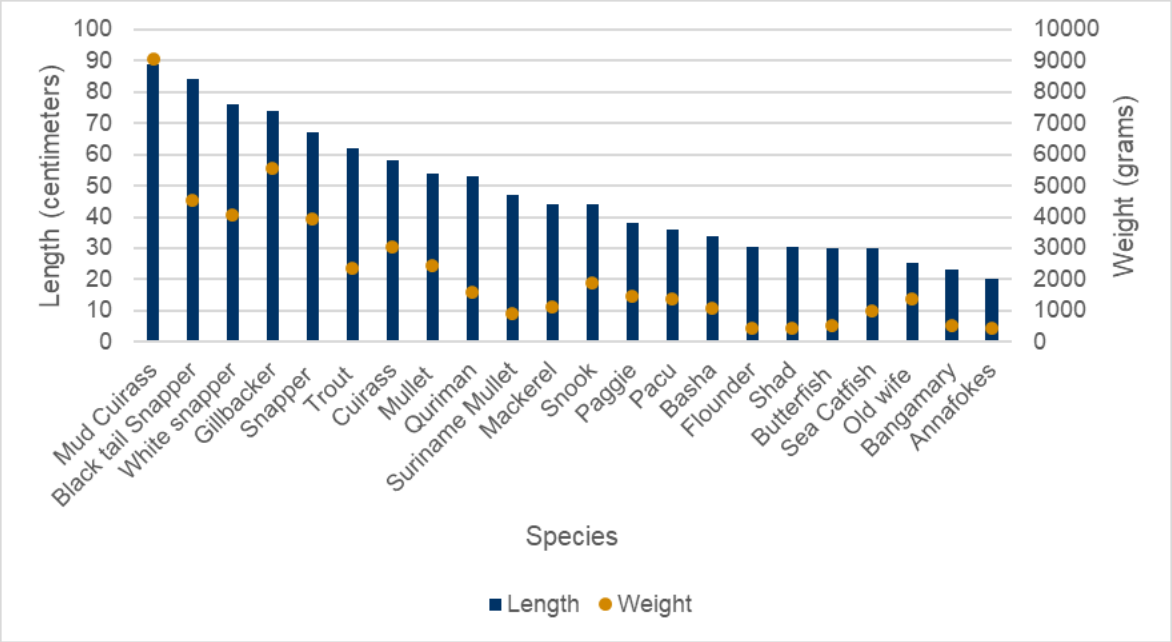

Figure Q-6: Average Length and Weight of Fishes Caught by the Bushlot Onboard Supervisor

The monthly average lengths and weights of the four most abundant species caught are presented on Figure Q-7. All the fishes measured had reached maturity. The largest sea catfish, cuirass, and gillbacker were caught in June and July 2019, after which there was a decline in sizes. This may have been due to more mature females with eggs coming closer to the shoreline to spawn in lagoons, estuaries, and mangroves during June and July. This trend is also seen in the data recorded at several other landing sites, like Smith's Creek (Region 1) and Charity (Region 2) where smaller fishes are caught when the spawning season ends. Mullet was only caught during September 2019 to February 2020. This may be related either to the fishing grounds preferred by the supervisor during this period or an interception of migratory mullet.

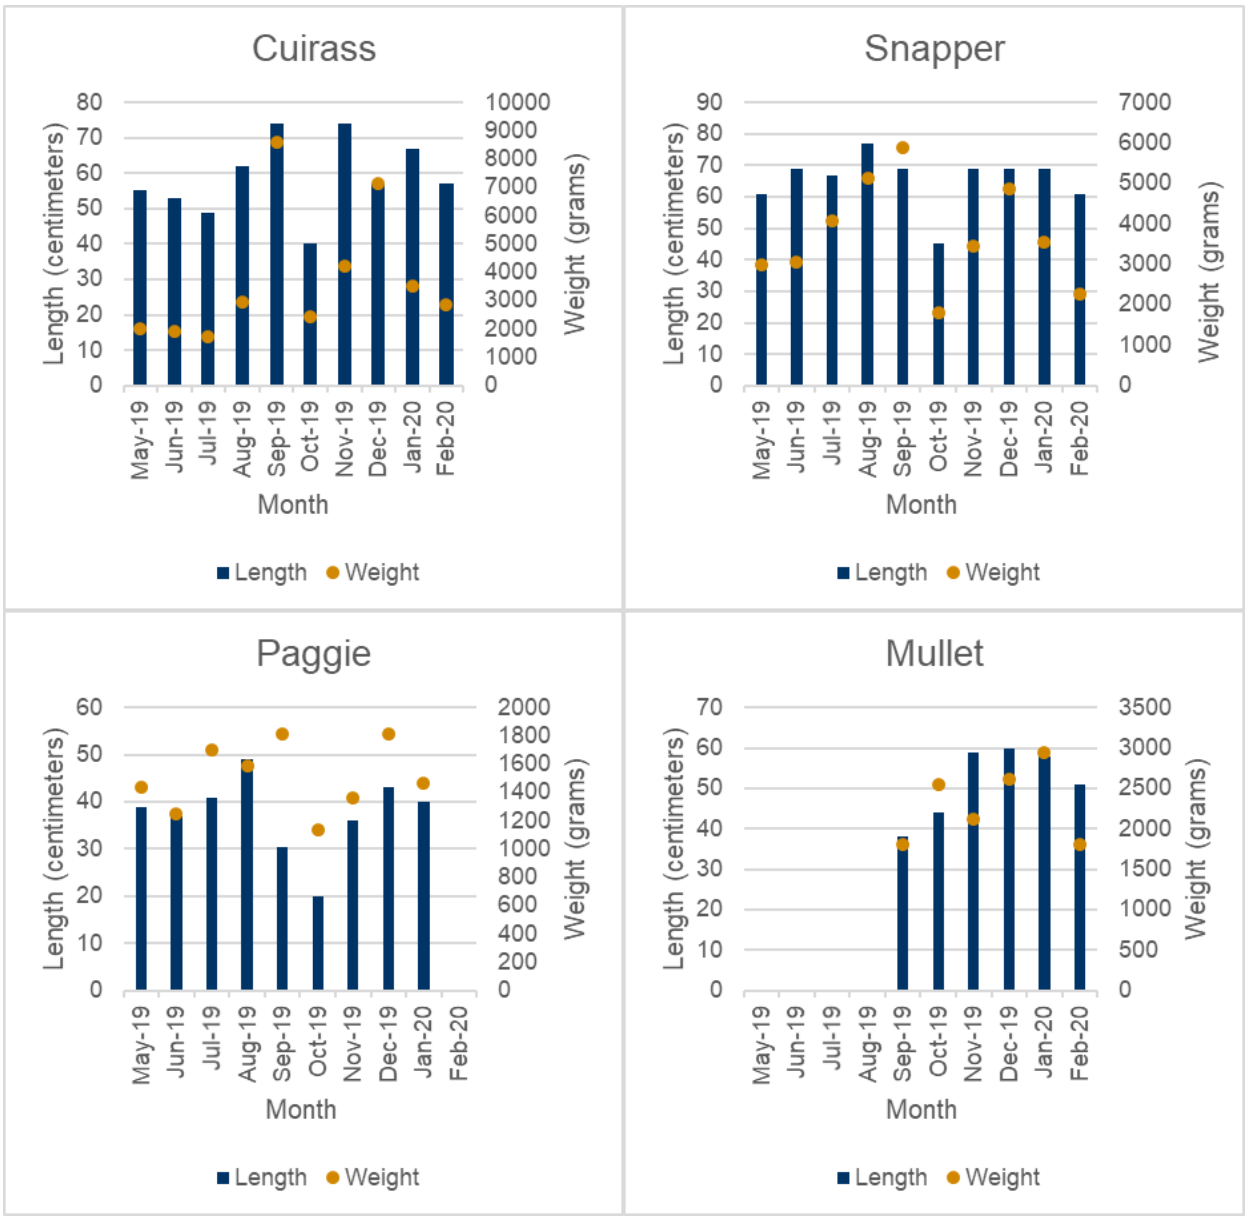

Figure Q-7: Total Weight of Species Recorded by the Bushlot Onboard Supervisor

3 QA/QC DATA

The first QA/QC exercise was conducted in October 2019 for one of the fishing trips conducted by the onboard supervisor. During this trip, the supervisor spent 14 hours at sea and fished along the Bush Lot coastline using a drift seine with mesh sizes of 12.7 centimeters (5 inches). The most abundant species caught during this fishing trip were cuirass and paggie (see Figure Q-8).

During the second QA/QC exercise in January 2020, a GoPro camera was installed on the vessel belonging to the onboard supervisor from the Bushlot landing site (see Figure Q-9). Several key observations were made from the video monitoring:

- The supervisor used drift seines with mesh sizes of 11 centimeters (4.5 inches). This seine had smaller mesh sizes than the most frequently used, which was 18 centimeters (7 inches), or the seine

used during the first QA/QC exercise that had mesh sizes of 12.7 centimeters (5 inches). The onboard supervisor did not use other methods to fish.

- The supervisor using the sail boat traveled to the fishing site in 30 minutes. The site was noticeably close to shore as the shoreline was still clearly visible in the video.
- The seine was soaked twice. The first was made at 1330 hours and left for 4 hours. During this soaking, the supervisor actually swam to shore to recover floats. Upon return to the vessel, the sea level was so shallow that the supervisor waded back to the vessel. The seine was soaked for a second time at 1830 hours and was left overnight while the onboard supervisor slept on the vessel.
- The catch from the first haul of the seine was stored on ice overnight in the vessel.
- The entire trip lasted for 18 hours.
- No bycatch were observed.

During the QA/QC exercise, the supervisor recorded a total haul of 40 kilograms (88 pounds) during the two soakings. This showed a deviation from the average recorded in the month of January 2020 by the supervisor, which was 40 kilograms (88 pounds) for only one soaking. However, this may have been a less productive fishing trip. The average haul per soaking in December 2019 was 30 kilograms (66 pounds). The differences in the haul may also be due to the distance at which the fishing was conducted relative to the shore and to the mesh sizes of the seines used. In addition, there were no significant deviations in catch composition or species diversity. However, the use of seines with smaller mesh sizes allowed the capture of smaller species such as the Suriname mullet.

During both of the QA/QC exercises, the study coordinator also took biometric measurements of the same fishes that were measured by the onboard supervisor and no data deviations were observed (Figure Q-10). Overall, the study coordinator was satisfied that the onboard supervisor was accurately recording the commercial species caught and following the guidance provided in taking biometric measurements.

APPENDIX R ROSIGNOL (REGION 5)

1 LANDING SITE OVERVIEW

Rosignol is the largest landing site in Region 5, and a cooperative called the Rosignol Fishermen's Cooperative Society (RFCS) manages the site. According to the RFCS, more than 40 vessels use this landing site, use a range of fishing gear, and are outfitted with outboard engines of 25 to 60 hp. Fishing trips by large vessels with 60 hp engines are at a distance of about 24 kilometers (14.9 miles) from the coastline and 27 meters (88.6 feet) of depth. These larger vessels may spend up to 2 weeks at sea. Smaller vessels usually fish up to 5 kilometers (3.1 miles) from the coastline and up to 5 meters (16.4 feet) of depth, and generally return to port daily. Fisherfolk reported soak times of 2 to 6 hours.

Species caught at this site are characterized as "mixed fish" including bangamary, trout, basher, gillbacker, snapper, shark, etc. Larger vessels have a yield of up to 454 kilograms (1,000 pounds) per trip that is sold at the landing site for $600 to $1,600 GYD ($2.9 to 7.7 USD) per kilogram depending upon the season. The main expense is fuel with fishing trips costing about $5,000 GYD ($24 USD) for smaller vessels and $240,000 GYD ($1,148 USD) for the larger vessels that spend extended periods at sea.

Fisherfolk at this landing site indicated that one of the main challenges they encounter is conflicts with trawlers and the risks of pirate attacks while at sea. Fisherfolk also contended that overfishing is prevalent and has depleted fish stocks. As a result, greater effort is required by fisherfolk to achieve hauls that make their fishing practice economically feasible.

2 ONBOARD SUPERVISOR RESULTS

The onboard supervisor at this landing site who participated in the study targeted snapper during the study period. The onboard supervisor at this landing site used drift seines of 4.5, 5, and 7.5 inches (10, 13, and 19 centimeters, respectively) mesh sizes on an alternating basis. The selection of gear type is based largely on the supervisor's experience of which fishes are typically more abundant at certain time periods and also by recent success using particular gear types. During the study period of June 2019 to February 2020, the drift seines with mesh sizes of 19 centimeters (7.5 inches) was most frequently used with the target species of snapper and trout. The vessel has a haul capacity of 450 kilograms (992 pounds) and is powered by a 60 hp engine. Each fishing trip lasts for approximately 10 days and has a five-member crew.

The onboard supervisor uses a variety of fishing grounds extending up to the Demerara River to the west and eastward into Surinamese waters. The main expenses per fishing trip are for rations for the crew, fuel, and ice for the preservation of the haul. Hauls from the onboard supervisor are sold to vendors who visit the landing site to purchase fishes for export and local sale. The supervisor did not encounter any challenges that significantly affected fishing practices during the study period.

2.1 Target Species and Diversity

The total weights of combined hauls from the onboard supervisor's vessel over the period April 2019 to February 2020 was 3,949 kilograms (8,706 pounds) from 2,208 hours of effort during the study period. The most abundant species caught was snapper, with a total weight of 1,963 kilograms (4,328 pounds) representing 50 percent of the supervisor's haul (see Figure R-1). The second and third most abundant species caught were trout and cuirass, respectively. Trout had a total weight of 586 kilograms (1,291 pounds), which accounted for 14 percent of the total haul, while cuirass had a total weight of 548 kilograms (1,208 pounds) accounting for 13 percent of the total haul. Snapper and trout were the two most abundant species caught at landing sites in Charity (Region 2) and Complex 66 (Region 6) as well, where drift seines with mesh sizes of 18 centimeters (7 inches) was used. Similarly, cuirass was the most abundant species caught at the Bushlot landing site (Region 5) where the main type of gear used by the

onboard supervisor was drift seines with mesh sizes of 18 centimeters (7 inches). Overall, 13 species were caught, six of which were caught in low quantities of 100 kilograms (220 pounds or lower). Among these six least-caught species were bonito fish, a species of small tuna that was not recorded by any of the other regional or onboard supervisors.

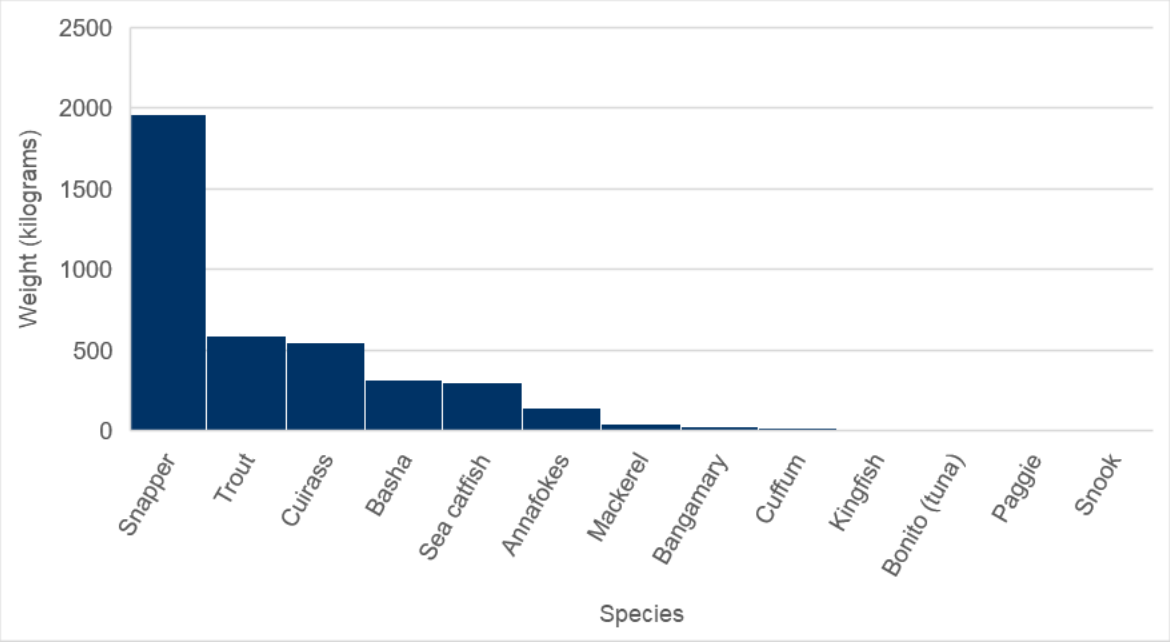

Figure R-1: Total Weight of Species Recorded by the Rosignol Onboard Supervisor

2.2 Fishing Areas

The onboard supervisor covers the second largest traveling range within the study participants with 6,076 square kilometers. Due to the expanse of the traveling range, fishing points were observed around main clusters, all of which were located around the mouths of rivers:

- The largest cluster covered an area of 1,743 square kilometers with fishing points at the mouths of the Mahaica and Berbice rivers, and also along the Region 5 coastline between these two rivers. Most of the fishing points in the hard season were located in this cluster particularly around the mouth of the Mahaica River.
- The second largest cluster covered an area of 1,015 square kilometers with fishing points around the mouth of the Corentyne River.
- The smallest cluster covers an area of 546 square kilometers with fishing points around the Coppename River in Suriname. These fishing grounds were approximately 191 kilometers from the landing site, the farthest the onboard supervisor traveled to access the fishing grounds. Fishing was only conducted at these fishing points during the good/peak season.

Based on the spread of the fishing points, there are clear seasonal patterns in the onboard supervisor's fishing activities as seen on Figure R-2. In particular, the onboard supervisor fished farther offshore and farther away from the landing site during the peak season. Waters are reportedly calmer during this period and therefore, more conducive to traversing greater distances. However, greater effort was expended by the supervisor during the off-peak season indicating that there were longer fishing trips likely

due to more effort and also rough seas that would have hampered normal traveling for the supervisor. Additionally, the onboard supervisor indicated that initial soakings of the seine did not yield economically viable hauls and as a result, more time was spent at sea looking for alternative fishing grounds in which the seine could soaked again.

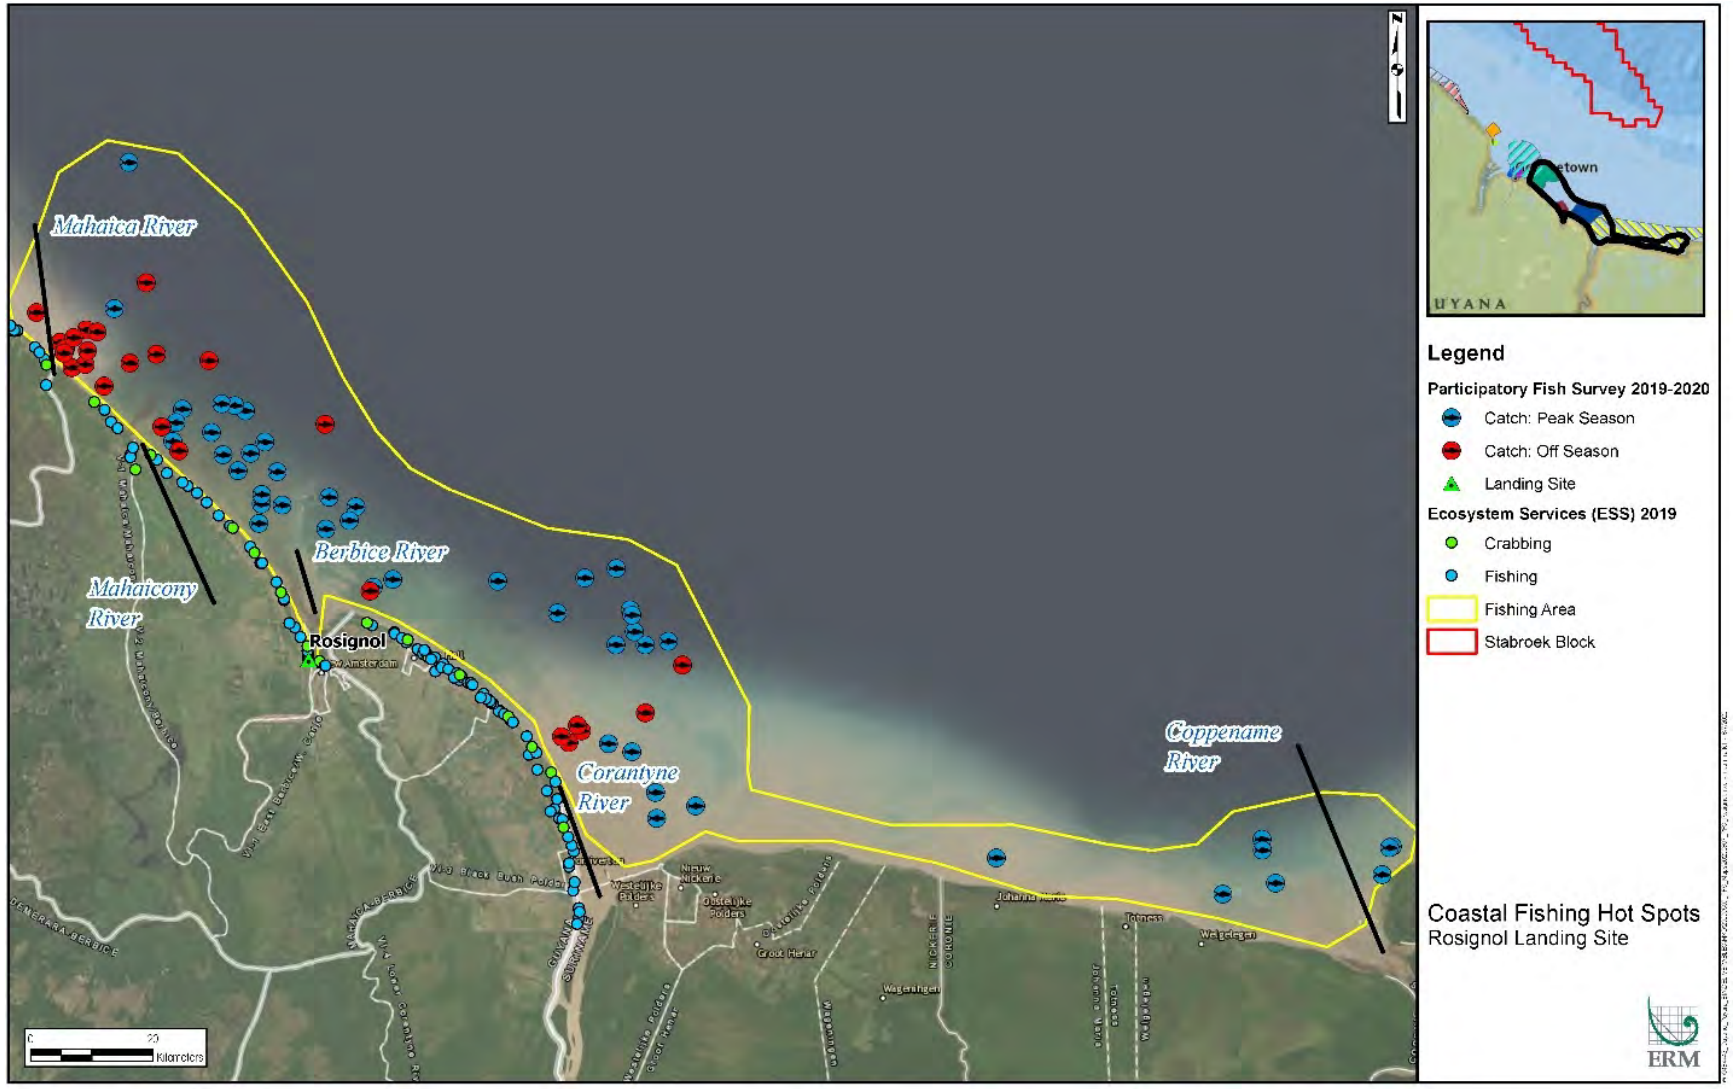

Figure R-2: Fishing Area and Fishing Points Used by the Rosignol Onboard Supervisor

2.3 Seasonal Productivity

The onboard supervisor subscribes to the commonly-held view that fishing is most productive from May to September (the so-called “good season” that peaks in July to September) and less productive from October to March (the so-called “hard season”). It is widely believed that waters are warmer and calmer during the good season, and these conditions are more conducive to fishing. These seasons are believed to influence effort expended by fisherfolk as well as hauls per soaking of the seine and per fishing trip.

During the study period, the onboard supervisor spent an average of 245 hours per month fishing, but there were variations in the effort expended per fishing trip on a monthly basis as seen on Figure R-3. The onboard supervisor’s monthly effort peaked in December 2019 with 384 hours of fishing activity. The lowest effort was expended in June 2019 and February 2020 with 120 hours of fishing activity for both. As seen on Figure R-4, the greatest total hauls were recorded in August 2019 with 903 kilograms (1,991 pounds). The highest average weight of hauls per soaking was recorded in June 2019 with 172 kilograms (379 pounds) as seen on Figure R-5.

Seasonal variations in effort and productivity were observed as follows:

- In the June to September 2019 good season, the total weight of hauls was 2,793 kilograms (6,158 pounds) with 1,008 hours spent at sea. On average, soaking of the seine in this period yielded 79 kilograms (174 pounds). June to August was the most consistently productive period. June 2019 was particularly notable because it was the month in which the highest average weight per soaking was recorded, the month with lowest effort, and one of the months with the greatest total hauls.

- In the October 2019 to February 2020 hard season, total weight of hauls was 1,156 kilograms (2,548 pounds) with 1,200 hours spent at sea. On average, soaking of the seine in this period yielded 24 kilograms (53 pounds). Hauls were consistently lower throughout this season than in the good season. During this period, December 2019 had the greatest total haul, but it was also the month in which the onboard supervisor expended the greatest effort.

By comparison, seasonal trends in the wet and dry season were as follows:

- In August to October 2019, the primary dry season, total weight of hauls was 1,247 kilograms (2,749 pounds) with 696 hours spent at sea. On average, soaking of the seine in this period yielded 37 kilograms (82 pounds).

- In June to July 2019, the primary wet season, total weight of hauls was 1,704 kilograms (3,757 pounds) with 456 hours spent at sea. On average, soaking of the seine in this period yielded 116 kilograms (256 pounds).

- In February 2020, which is considered within the secondary dry season, the total weight of hauls was 109 kilograms (240 pounds) with 120 hours spent at sea. On average, soaking of the seine in this month yielded 21 kilograms (46 pounds). Data collection at this site did not commence until June 2019 and therefore, there will be a data gap for April to complete this season.

- In November 2019 to January 2020, the secondary wet season, total weight of hauls was 888 kilograms (1,958 pounds) with 936 hours spent at sea. On average, soaking of the seine in this period yielded 23 kilograms (51 pounds).

Based on the trends discussed above, productivity of fishing activities adhered to the belief of fisherfolk pertaining to the good and hard seasons. Average haul per soakings was also greater during the good

season as compared to the hard season. The trends also demonstrated that the relationship between effort expended and total haul is also ultimately determined by the seasons. In particular, in the hard seasons, greater effort is not an indicator of greater productivity, and in the good seasons, greater productivity required a disproportionate level of effort. For example, similar levels of effort were expended in June 2019 and February 2020, but the greater average weight of hauls per soaking in June 2019 resulted in significantly higher total hauls. On the other hand, while the greatest effort was expended in December 2019, it was not the month with the highest haul. Total hauls are expected to be greatest when high levels of total effort are expended when the average weight of hauls per soaking are the highest.

As a result of the higher productivity of the good season, productivity was also higher in the primary wet and dry seasons. These trends are evident although additional data are needed to complete the seasonal data sets for the primary wet season and the secondary dry season. Within the timeframes of the good and hard seasons, productivity of hauls was highest in the wet seasons. As such, it may be concluded that the hauls per soaking of the seine are most productive during the wet seasons because fishing is done primarily around the river mouths. According to Lowe-McConnel (1962), nutrient flows are increased during the wet season and fishes are expected to be more abundant at river mouths during this season.

However, as previously indicated, given the sharp decline in productivity in September 2019, the onboard supervisor has asserted that the good season may be shorter than is currently believed. Sharp reductions in productivity were also observed at other landing sites during the good season. For example, productivity sharply declined in August 2019 based on data collected from onboard supervisors at landing sites in Windsor Forest (Region 3) and Riverview (Region 4). The onboard supervisor asserted that the changes in productivity at the landing site, especially the shortening of the good season, coincided with the commencement of oil drilling activities offshore. It is believed that the noise, vibrations, and lights associated with drilling activities attract fishes to the vicinity of the drill sites thereby reducing the abundance in the fishing grounds preferred by artisanal fisherfolk. Additional data have to be collected to determine whether the reasons for these declines are localized to the landing site and whether there is indeed a varied periodicity of the good season at different landing sites.

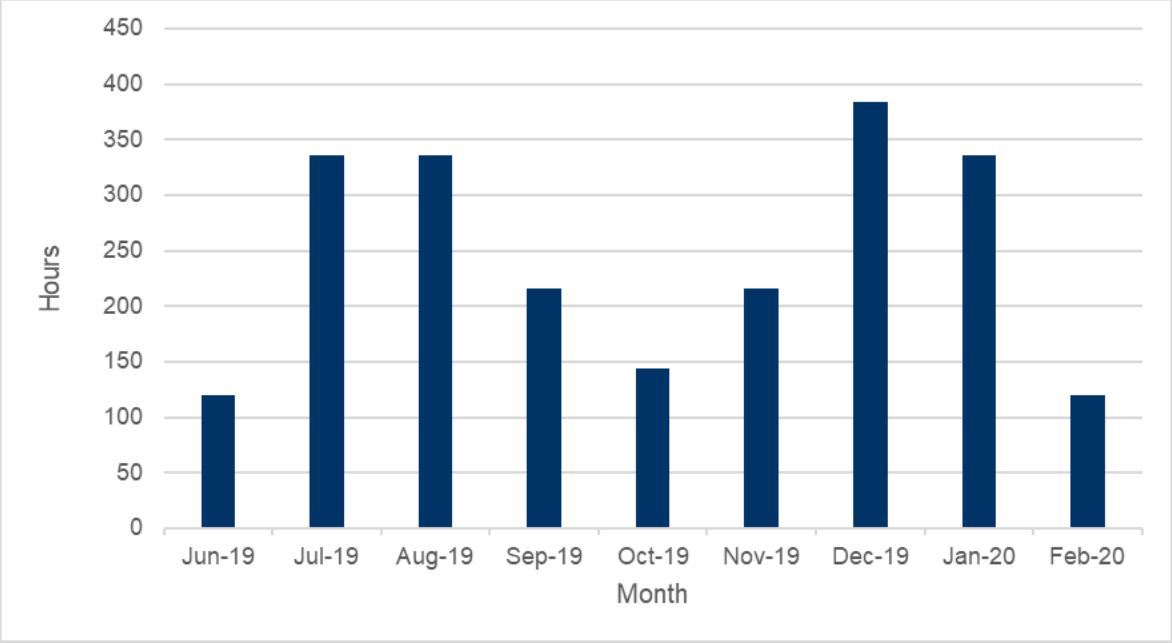

Figure R-3: Total Monthly Fishing Effort Recorded by the Rosignol Onboard Supervisor

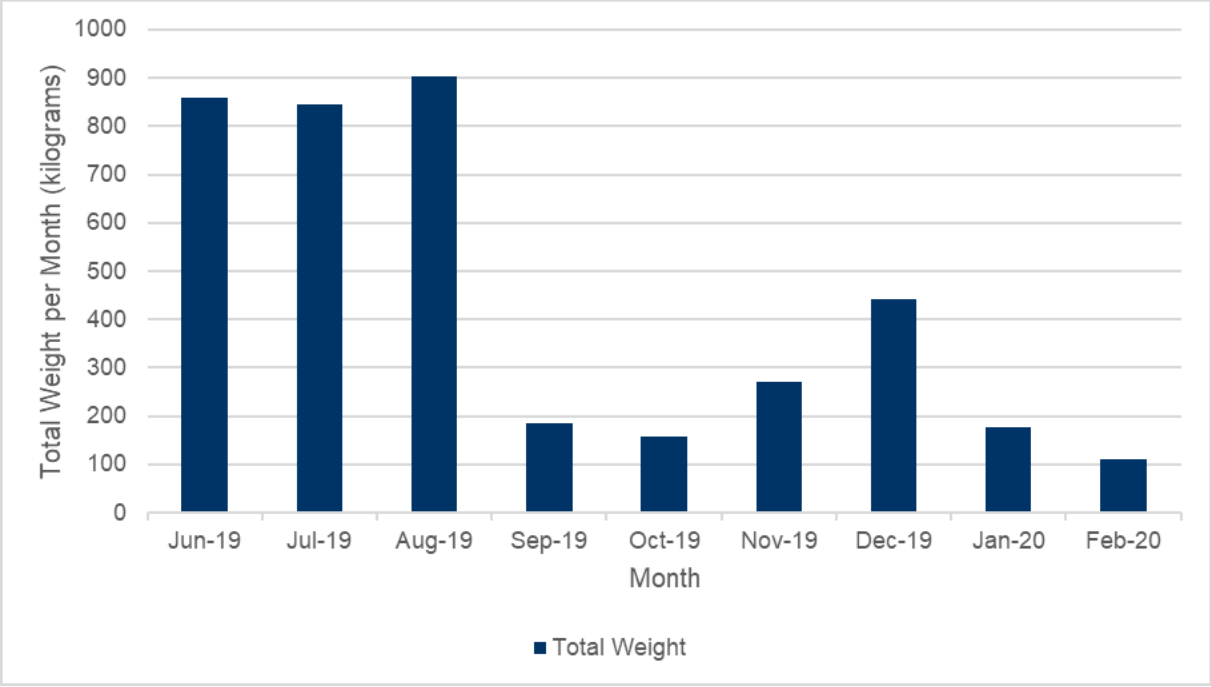

Figure R-4: Total Monthly Weight Recorded by the Rosignol Onboard Supervisor

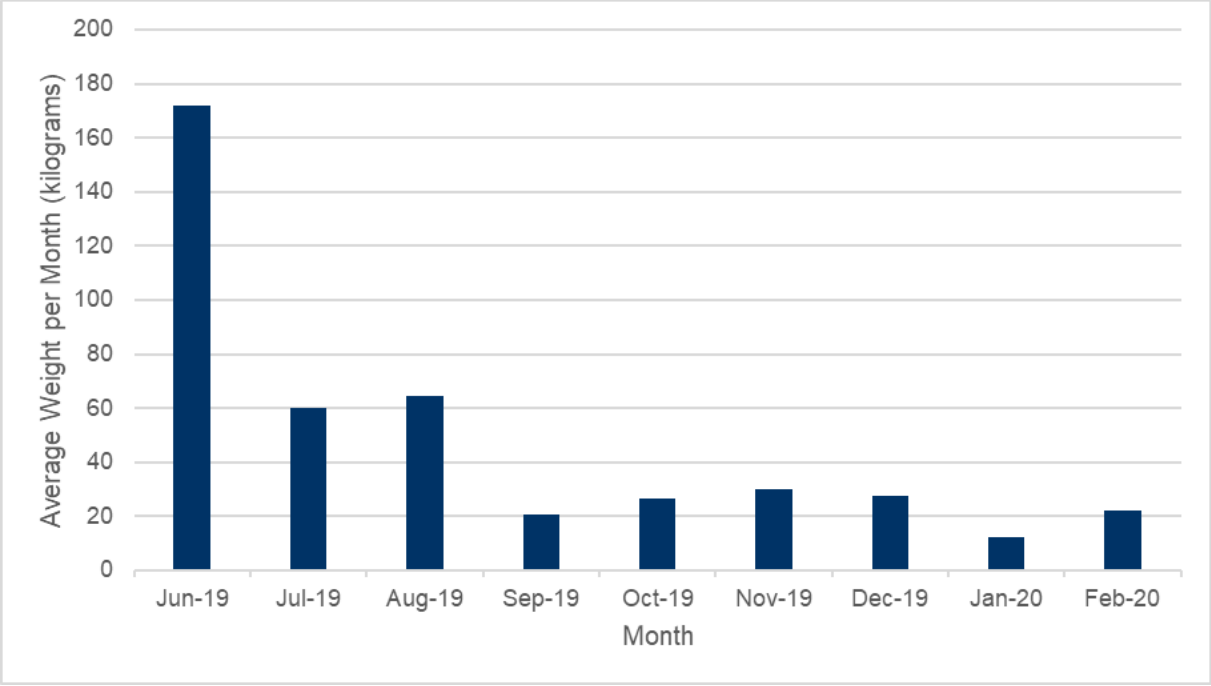

Figure R-5: Average Weight per Soaking Recorded by the Rosignol Onboard Supervisor

2.4 Biometrics

The onboard supervisor measured the lengths and weights of representative fishes per each haul and the annual average lengths and weights of these fishes are shown on Figure R-6. Based on the

measurements taken by the onboard supervisor, all the fishes caught were sexually mature. The annual average lengths of some of the fishes caught at this landing site are among the largest reported by the study. For example, the target species, snapper and trout, had annual average lengths of 86 and 71 centimeters, respectively. This is larger than the annual average lengths of these fishes caught at Charity (Region 2), Bushlot (Region 5), and Complex 66 (Region 6) where drift seines with mesh sizes of 18 or 19 centimeters (7 or 7.5 inches) were used. However, the onboard supervisor at Hampton Court (Region 2) used a drift seine with mesh sizes of 20 centimeters (8 inches) and caught snapper, which were larger (annual average length of 94 centimeters). A relatively small pool of biometric data was recorded by the onboard supervisor on a monthly basis and as such, a comparison of the monthly trends in sizes of the most abundant species caught cannot be done for this landing site.

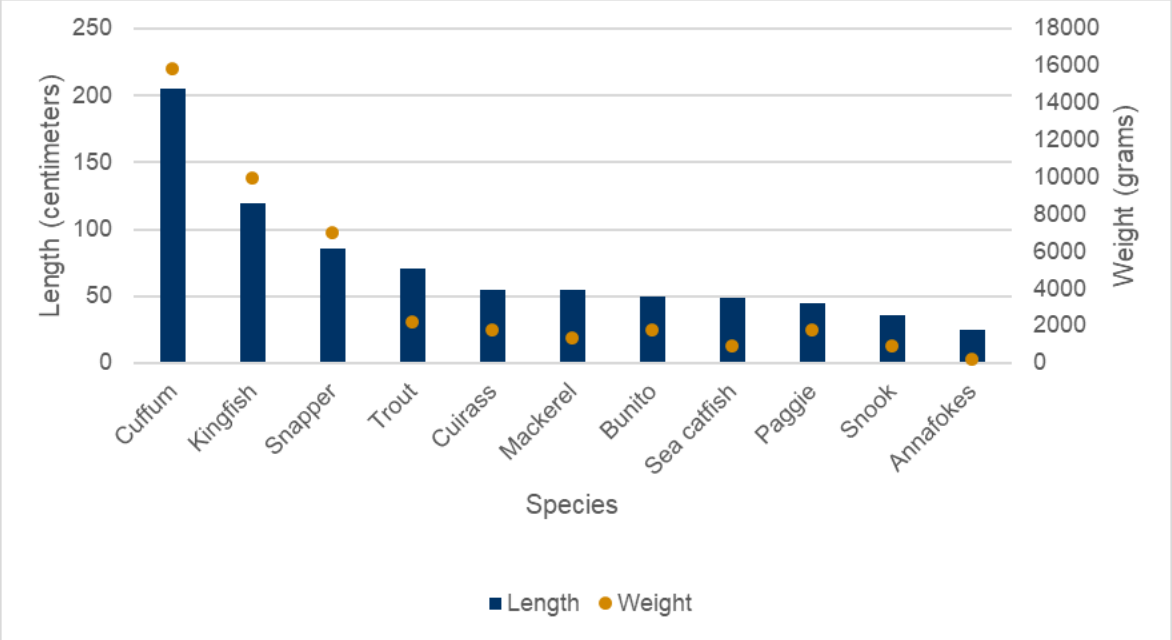

Figure R-6: Average Length and Weight of Fishes Caught by the Rosignol Onboard Supervisor

3 QA/QC DATA

In October 2019, the study team intended to meet with the onboard supervisor's vessel when it landed to assess the haul, take biometric measurements, and compare these results to the data collected by the onboard supervisor. This could not be accomplished due to changes in the supervisor's expected return date. As a result, the team could not conduct QA/QC assessment of the data collected by the onboard supervisor. However, the study coordinator assessed the haul from a vessel at the Rosignol landing site that also used drift seines with mesh sizes of 18 centimeters (7 inches). The vessel had returned from an 8-day fishing trip where seines were soaked multiple times. The vessel used a 60 hp outboard engine. The data collected by the study team from this vessel were consistent with the data collected by the onboard supervisor. The target species, snapper, was the most abundant species caught (Figure R-7). The haul also had relatively low species diversity that is typical of this type of fishing. The biometric data collected are similar to that observed by the supervisor at this site. Snapper is normally the largest of the fishes caught using this fishing method and this is consistent with biometric measurements taken by the onboard supervisor (see Figure R-8).

In January and February, 2020, the team tried to conduct QA/QC exercises at the landing site. The study team made arrangements to meet the onboard supervisor when the vessel landed. However, the vessel landed earlier than scheduled, and the haul was sold out before the team's arrival on both occasions. In addition, there were no landed vessels that could be assessed during visits to the landing site.

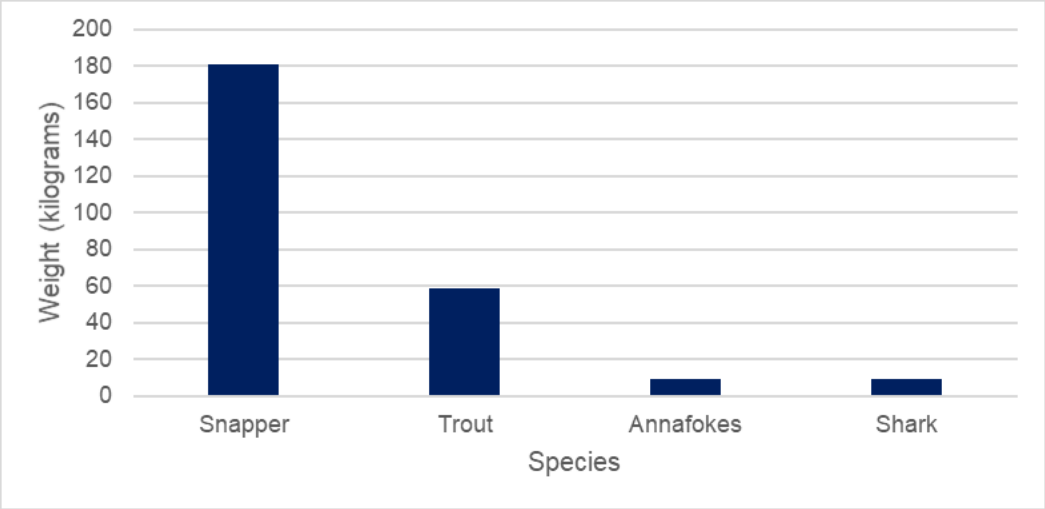

Figure R-7: Catch Composition of Commercially Viable Species during the QA/QC Exercises

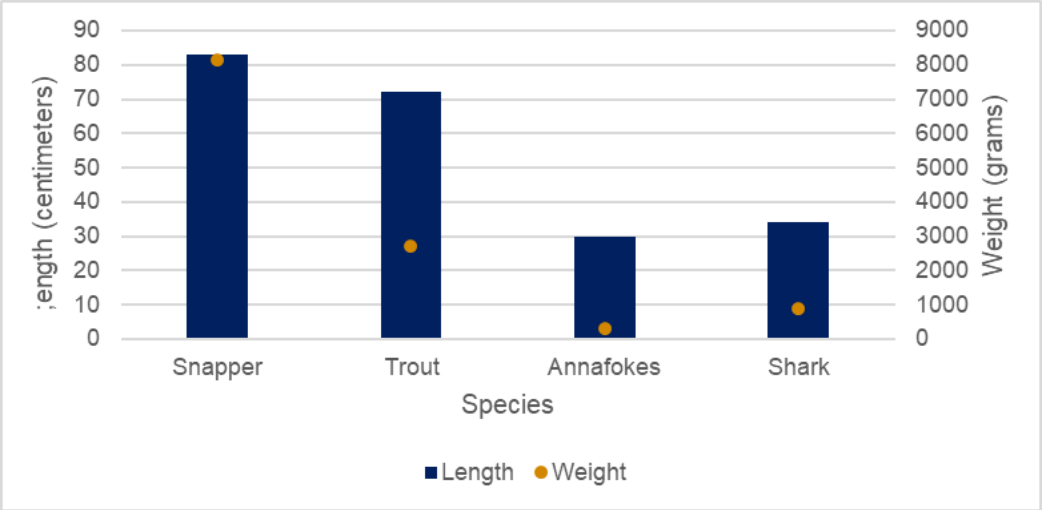

Figure R-8: Biometric Measurements Collected for the Rosignol Landing Site

APPENDIX S ROSE HALL (REGION 6)

1 LANDING SITE OVERVIEW

Rose Hall is the only landing site in the study where fisherfolk exclusively use pin seines for nearshore fishing. During the baseline data collection in February 2019, four fisherfolk were actively using the landing site. However, the number of fisherfolk operating at the landing site declined due to migration and by February 2020, only two fisherfolk continued to use the landing site. Both of these fisherfolk use pin seines with mesh sizes of 2.5 to 3.8 centimeters (1 to 1.5 inches) and target shrimp.

During the April 2019 to February 2020 period, the fisherfolk at this landing site experienced several challenges that significantly curtailed and temporarily stopped their fishing activity. In the aftermath of the spring tides in September 2019, significant quantities of mud and "caddy," a hard black sand and seashell mixture, were deposited on the seashore. Under these conditions, fisherfolk reported difficulties in accessing the landing site and setting up their seines. In addition, in January and February 2020, fisherfolk reported that the seas became too rough to continue fishing. Rough waters caused the seines to break down causing losses of catch. Fisherfolk also incurred costs to repair the seines that were damaged. As a result, all activities at this landing site ceased in January and February, and for most of March 2020. By the end of March 2020, fisherfolk indicated that waters were once again calm enough to allow the resumption of fishing activities.

Fisherfolk also indicated that lack of available markets to sell their produce was also a challenge.

2 REGIONAL SUPERVISOR RESULTS

One regional supervisor participated in the study and the results in this section were provided by him over the course of the study period.

2.1 Effort and Haul

Based on the data collected by the regional supervisor, shrimp was the most abundant species caught by weight with 4,156 kilograms (9,162 pounds), accounting for 78 percent of the total weight caught (Figure S-1). It should be noted that both white belly shrimp and corse shrimp were caught by the fisherfolk but were not reported separately by the regional supervisor. Bangamary was the second most abundant species caught with a total weight of 633 kilograms (1,396 pounds). Similarly, at the landing site in Zeeburg (Region 3) where Chinese seines are used to target white belly shrimp, the most abundant species caught was the white belly shrimp that accounted for 85 percent of the total haul, while the second most abundant species caught was bangamary. Long head cuirass and butterfish were the third and fourth most abundant species caught at the Rose Hall landing site, but at significantly lower quantities than shrimp and bangamary. In addition, small quantities of high-value species like snapper, prawns, and trout were also reported. In fact, prawns were only reported at this landing site and by the regional supervisor at the Riverview landing site in Region 4. In addition, due to the close proximity of the pin seine sites to the coast, small quantities of crabs were also reported. In total, recorded hauls at this landing site had a total weight of 5,325 kilograms (11,805 pounds).

Pin seine fishing requires significantly lower effort than other types of fishing, and in favorable conditions can be conducted on a daily basis. Generally, effort expended on fishing using pin seines is constant throughout the year. Fisherfolk set pin seines less than 1 kilometer offshore of the Rose Hall beach. Fisherfolk set the pin seines during low tide and leave them to soak for 12 hours. When low tides return, fisherfolk return to their seines using catamarangs or flat-bottom boats to recover the catch. This activity generally occurs once daily. However, if the first tide cycle occurs early in the day, fisherfolk may fish twice in one day.

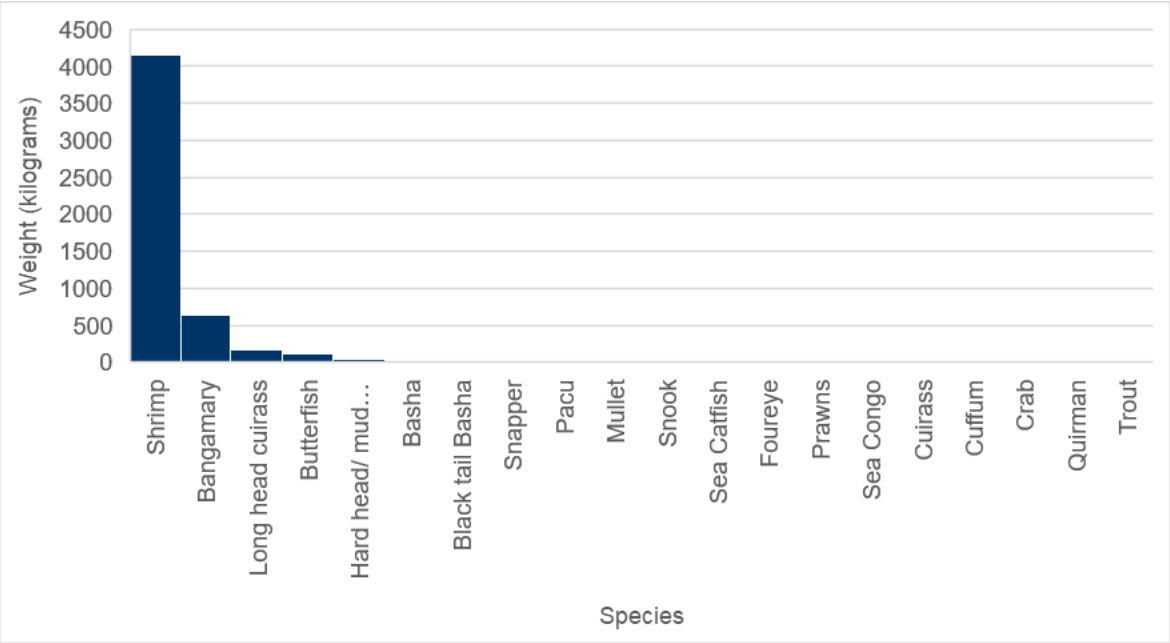

Figure S-1: Total Weight of Species Caught at the Rose Hall Landing Site

2.2 Target Species and Diversity

A total of 21 commercially viable species were caught at this landing site (Figure S-2). Species diversity peaked in July and was consistently high from May to August 2019. This may be attributed to more fish species coming closer to shore to feed during the raining season of May to July and to spawn from July to September. The diversity of species caught sharply declined in September 2019 as fishing activities were curtailed due to the spring tides and their aftermath. Bycatch is not recorded by the regional supervisor at this landing site as fishes not considered commercially viable are discarded at sea around the seines. This attracts birds to the area to feed on the discarded catch. In addition, it is likely that this also attracts more shrimps and fishes to this area to feed, which may then be caught in the pin seines.

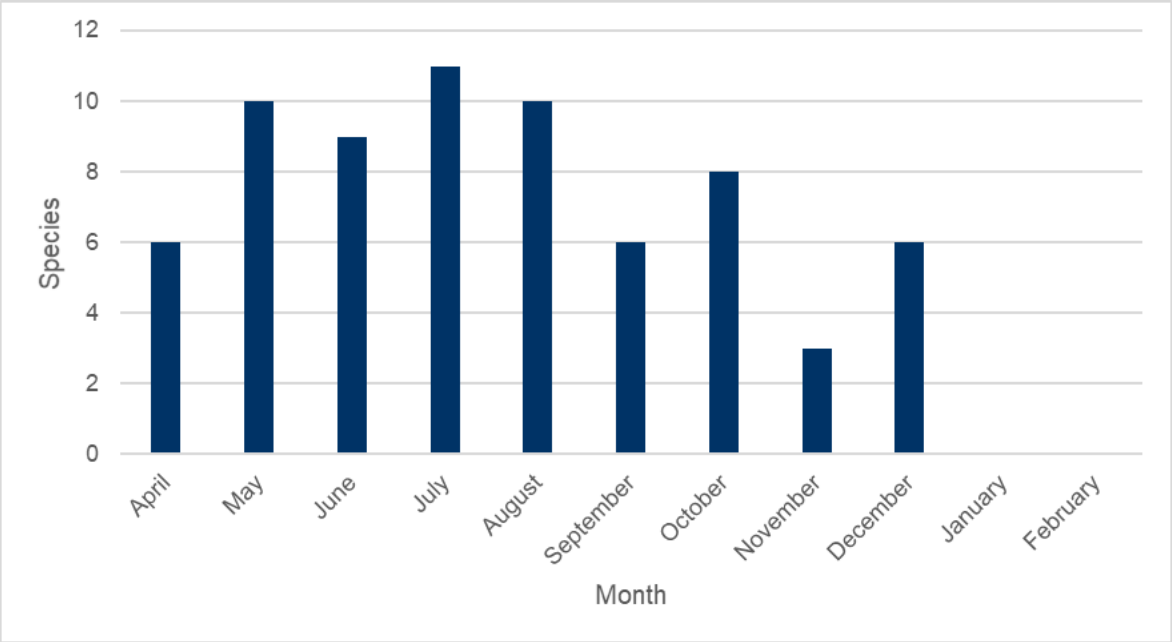

Figure S-2: Species Diversity

2.3 Seasonal Productivity

Artisanal fisherfolk believe that the peak and off-peak seasons for fishing occur from April to September and October to March, respectively. On the other hand, some fisherfolk have asserted that there are no seasonal variations for pin seine fishing because hauls are dependent on what species are closest to shore when the seines are set. However, this is not considered applicable to this landing site because the majority of the hauls comprise shrimp. There are varying beliefs on the most productive months for shrimping. Some fisherfolk indicated that shrimp catch generally increases during the closed trawl season, which occurs from August 16 to October 05 annually, and others indicated that productivity increases during the dry seasons of February to April and August to September. Spawning seasons of white belly shrimps runs from January to April and June to July and may also contribute to increased productivity as white belly shrimp and corse shrimp/seabob may travel closer to shore to spawn in the mangroves.

Figure S-3 shows the average productivity of fishing trips on a monthly basis that is measured as the dividend of total monthly productivity and the total number of hauls per month. The most productive months were October and November 2019 when average productivity per haul was 48 kilograms (106 pounds) and 38 kilograms (84 pounds), respectively. Relatively high productivity was also observed in April and July 2019 with 31 kilograms (68 pounds) in each month. Lowest productivity was recorded in May, June, and December 2019 when average hauls were 20 kilograms (44.1 pounds) or lower. Given the temporary cessation of activities at the landing site in January and February 2020, no productivity was recorded during that period.

Disruptions to fishing activities in September 2019 and January to March 2020, in addition to challenges in collecting data from the regional supervisor in March 2020, have hindered the emergence of any clear trends for productivity in the dry seasons (August to October and February to March), the closed trawl season, and the January to April spawning season. Additional data are required to better understand seasonal productivity of shrimping using pin seines at this landing site. Moreover, it may also be useful to collect data for another landing site that uses pin seines exclusively to better understand whether the catch composition observed at Rose Hall is representative of pin seine fishing.

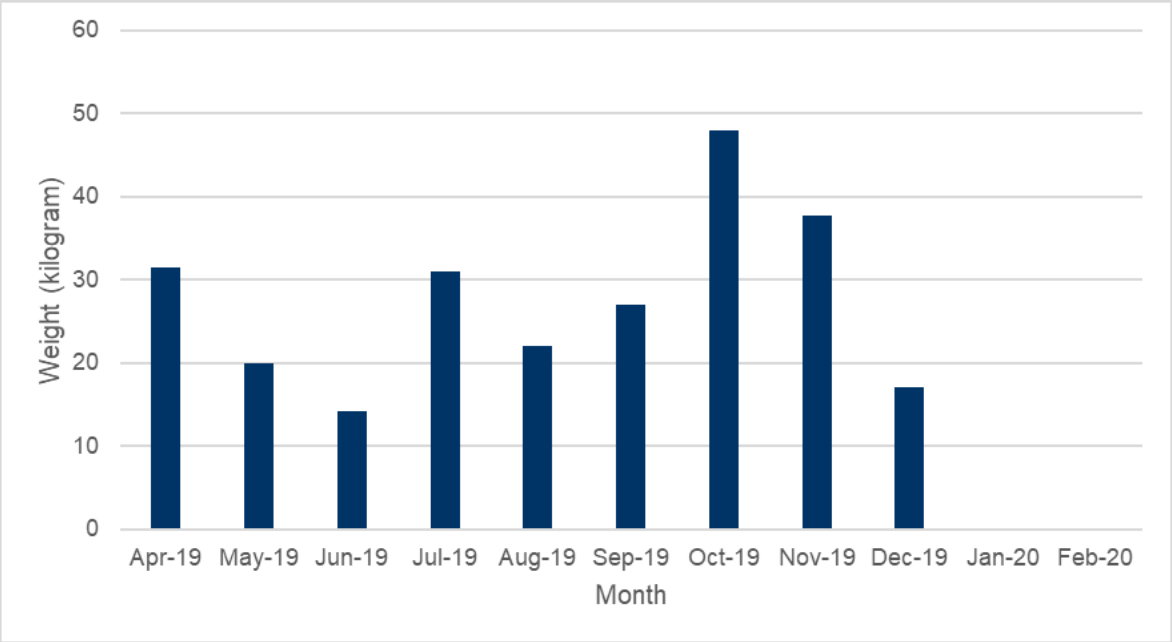

Figure S-3: Average Monthly Productivity of Hauls Recorded at the Rose Hall Landing Site

2.4 Prices and Markets

During the reporting period, snook and prawns were the highest-value species with annual average prices per kilogram of $1,261 GYD ($6 USD) and $1,220 GYD ($5.90 USD) as seen on Figure S-4. These prices, and prices for most other species caught at the landing site were significantly different than those reported by other regional supervisors, for example:

- The annual average price per kilogram of snook at Smith's Creek and Morahwanna (Region 1), where it was one of the most abundant species caught, was $405 GYD ($1.90 USD). At landing sites in Charity (Region 2) and Riverview (Region 4), annual average prices per kilogram for snook were $140 GYD ($0.70 USD) and $198 GYD ($0.90 USD) respectively.

- The annual average price per kilogram of snapper at Charity (Region 2), where it is the primary target species and the most abundant species caught, was $719 GYD ($3.40 USD). In fact, the annual average price per kilogram for snapper at Rose Hall of $905 GYD ($4.40 USD) is second only to the price obtained at the Mahaicony Bridge landing site of $959 GYD ($4.60 USD) where snapper is more expensive largely because of its scarcity at the landing site.

- The annual average price per kilogram of bangamary at Riverview (Region 4) and Mahaicony Bridge (Region 5), where it is the primary target species, were $223 GYD ($1 USD) and $225 GYD ($1 USD). In fact, the annual average price per kilogram for bangamary at Rose Hall of $479 GYD ($2.30 USD) is similar to the price of $415 GYD ($1.90 USD) obtained at Smith's Creek and Morahwanna (Region 1) where bangamary is more highly valued.

- The annual average price per kilogram of white belly shrimp was $261 GYD ($1.30 USD) at the Zeeburg landing site (Region 3), where it is the primary target species, compared with $448 GYD ($2.20 USD) per kilogram of 'mixed shrimp' at Rose Hall, where this is also the most abundant species caught.

- The annual average price per kilogram of trout at Charity (Region 2), Riverview (Region 4), and Mahaicony Bridge (Region 5) were $339 GYD ($1.60 USD), $620 GYD ($2.90 USD), and $592 GYD ($2.80 USD), respectively.

The reasons for these price differences compared to other landing sites may also be the primary factor influencing the considerable variations in minimum, maximum, and average prices of the four most abundant species caught shown on Figure S-5. Unlike the other landing sites where hauls are sold primarily to vendors for resale, the fisherfolk at Rose Hall take their catch to the Rose Hall Municipal Market for sale directly to consumers. In addition, fishes are not sold per kilogram but as single, whole fishes. In this way, fisherfolk set prices based on quantities caught per haul thereby ensuring that higher prices are reflective of scarcity. For example, the highest monthly average and maximum prices for the four most abundant species caught were observed in May, June, and December 2019, which were also the months when average productivity per haul was lowest. In addition, lower prices during the peak season may have arisen as a result of greater supply, and therefore greater competition, at the market place. There were also several months in which hauls did not include some species of fishes, and this may have further amplified perceived scarcity of these fishes. As seen on Figure S-5, butterfish was caught in September 2019 and not again until December 2019, at which time the price significantly increased. In January and February 2020 when the supervisors did not conduct any fishing activity, fisherfolk from the Rose Hall landing site sourced fishes and shrimps from New Amsterdam and Canje, approximately 10 kilometers away, to be sold in the Rose Hall Municipal Market.

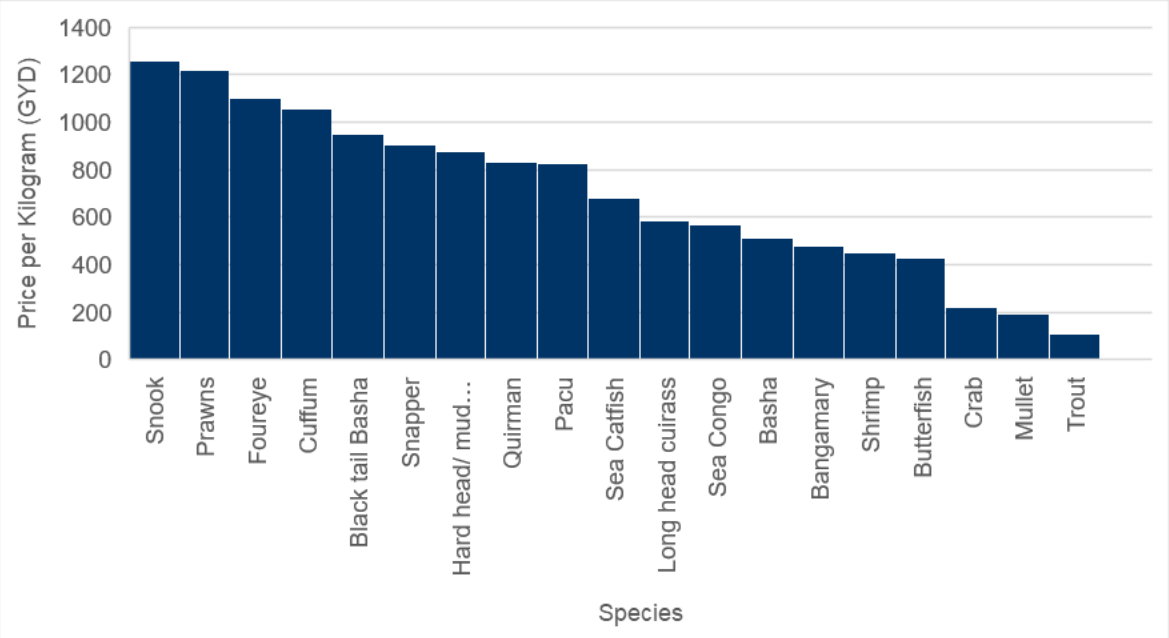

Figure S-4: Average price of Fishes Recorded at the Rose Hall Landing Site

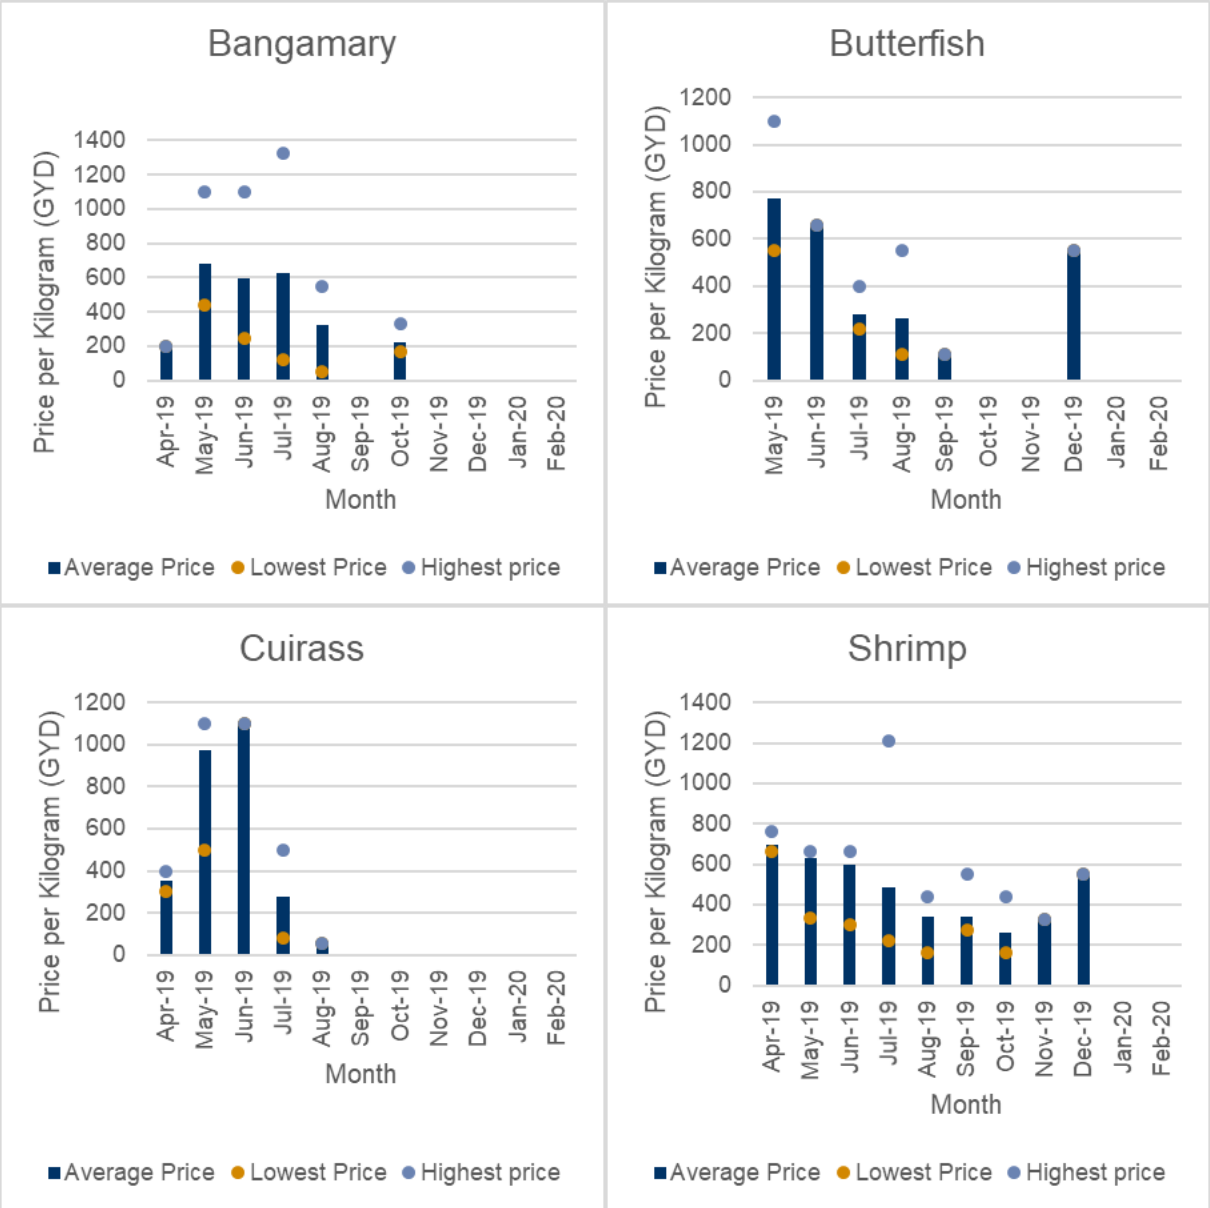

Figure S-5: Monthly Price Variations of the Four Most Abundant Species Caught

2.5 Biometrics

The biometric data collected from the landing site are reflective of the size inconsistencies typical for this type of fishing. Some species were sexually mature including cuffum, quirman, sea congo, long head cuirass, and hardhead/flat head cuirass. However, these species were caught in low quantities. Based on the annual average lengths, the main fish species caught, bangamary and butterfish, were not sexually mature (see Figure S-6).

Due to the inconsistencies with which the four most abundant fishes caught comprise hauls at the landing site in combination with measurements having not been taken for the shrimps, no trends are evident in the analysis of monthly variations in biometric data.

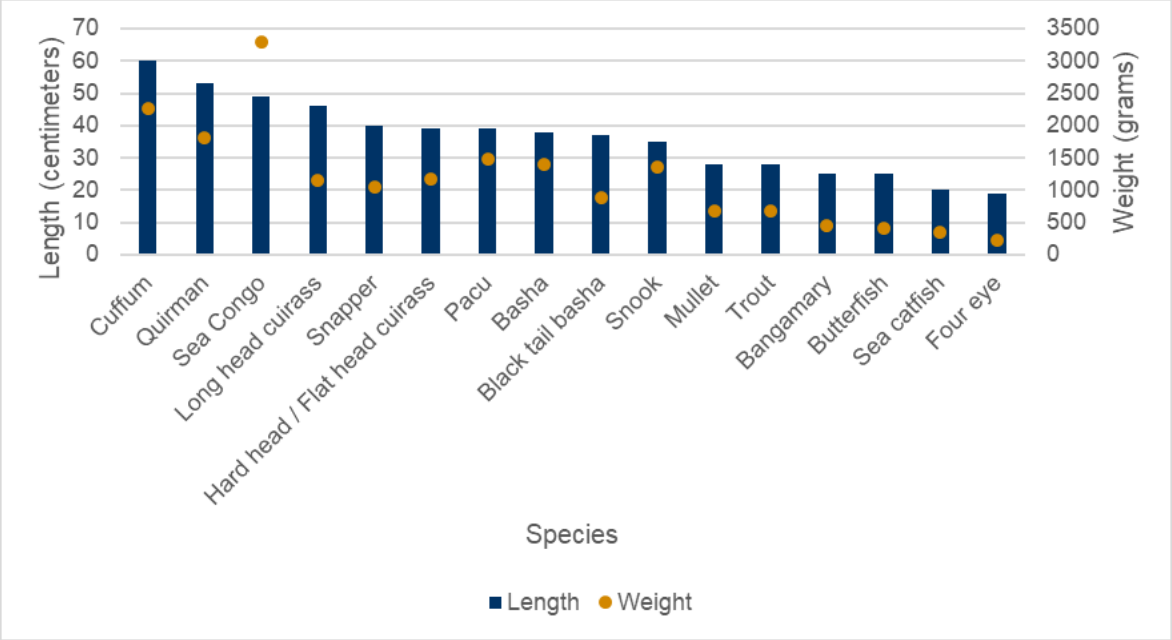

Figure S-6: Annual Average Lengths and Weights for Fishes Measured at the Rose Hall Landing Site

3 QA/QC DATA

The study coordinator assessed a haul from the regional supervisor's pin seine during the October 2019 QA/QC exercise. During the trip, the supervisor caught 5 kilograms (11 pounds) of corse shrimp/seabob (Figure S-7). This is typical of fishing at the site using the pin seine method and corresponded with the data collected by the regional supervisor during the July to September period. The study coordinator could not observe how the catch was sorted in the seine and see what species were determined to be commercially viable versus bycatch. In 2020, there was no fishing activity at the landing site and therefore, the QA/QC exercise could not be conducted.

Figure S-7: Catch Recorded from the Pin Seine Supervisor at Rose Hall

APPENDIX T ALBION (REGION 6)

1 LANDING SITE OVERVIEW

Albion is one of the largest landing sites in Region 6, and fisherfolk have indicated that 60 vessels use this landing site. All vessels are outboard cruisers fitted with engine sizes ranging from 15 to 50 hp. Most vessels are characterized as bangamary vessels because they use drift seines with mesh sizes of 7 centimeters (2.75 inches) and target bangamary. Other vessels are characterized as trout vessels that use drift seines of 4.5 inches and 7 inches (11 and 18 centimeters).

Fisherfolk from this landing site make daily trips along the Region 6 coastline typically traveling between the mouth of the Berbice River to the west, and Whim village to the east. Fishing occurs approximately 25 kilometers offshore at depths of 10 to 33 meters. Seines are soaked for 1 to 4 hours. According to fisherfolk, the main species caught at this site are bangamary, butterfish, trout, and sea catfish. A typical haul is approximately 300 kilograms (660 pounds) of fishes depending upon the season. Hauls are sold to vendors who visit the landing site with refrigerated trucks, who in turn sell the fish at markets in surrounding villages. Prices range from $160 to 300 GYD ($0.76 to 1.43 USD) per kilogram depending on the species and the season. The main expense is fuel with trips costing $6,000 GYD ($29 USD) for the bangamary vessels.

All fisherfolk interviewed at this location indicated that trawler vessels are a challenge because they frequently pass over and damage seines, causing the fisherfolk to lose catch and requiring seine repairs.

2 ONBOARD SUPERVISOR RESULTS

The onboard supervisor at this landing site who participated in the study uses a drift seine with mesh sizes of 7 centimeters (2.75 inches), referred to as a “bangamary seine” to target bangamary. Typically, fishing trips last for 12 hours at sea. The vessel has a haul capacity of 1,000 kilograms (2,200 pounds) and is powered by a 15 hp engine. Each fishing trip required a two-member crew inclusive of the onboard supervisor. Similar to the other fisherfolk at this landing site, the onboard supervisor fishes along the Region 6 coastline. Fuel is the most significant expense per fishing trip for the onboard supervisor and generally, fishes are not iced before returning to shore. Most of the haul is sold to vendors while the glue and trout are sold to exporters who visit the landing site with trucks. These fishing practices are similar to those described by the onboard supervisor at the Riverview landing site (Region 4), with the key difference being that the onboard supervisor at Riverview used a 40 hp engine.

2.1 Target Species and Diversity

The total weights of combined hauls from the onboard supervisor’s vessel over the period April 2019 to February 2020 was 11,472 kilograms (25,291 pounds) from 1,673 hours of effort. Bangamary, the target species at this landing site, was the most abundant species caught by a significant margin (Figure T-1). The onboard supervisor caught a total of 8,569 kilograms (18,891 pounds) of bangamary representing 75 percent of the total haul. In addition, trout and butterfish were the second and third most abundant species caught with 1,093 kilograms (2,409 pounds) and 870 kilograms (1,918 pounds) caught, respectively. Bangamary, butterfish, and trout were also the three most abundant species caught at all landing sites where the bangamary seines were the predominant gear type including the landing sites in Riverview (Region 4) and Mahaicony Bridge (Region 5). The fourth most abundant species caught was sea catfish and this was also the fourth most abundant species caught at the Riverview landing site.

Overall, 31 species were deemed commercially viable by the onboard supervisor of which 26 species caught were in low quantities of 100 kilograms (220 pounds) or less. Among these were high-value species like snapper and prawns as well as jewfish (an endangered, threatened, and protected species). This is one of only three landing sites where jewfish was reported as part of the hauls. Hauls including

jewfish were reported in October when the onboard supervisor was fishing in the normal fishing grounds along the Region 6 coastline. In total, only 0.45 kilogram (1 pound) of jewfish was caught as fisherfolk do not target this species. It is not known whether jewfish is typically caught in these waters during these months, and further research is needed to determine whether this may be linked to any particular behaviors, such as spawning or feeding behaviors, of this fish. Shark was caught in greater abundance than jewfish but were not identified by species and as such, it cannot be determined whether any of the fishes caught are endangered or vulnerable species. The onboard supervisor also recorded bycatch comprised mainly of rockhead and annafokes. Annafokes are considered a commercial catch by all of the other landing sites and some landing sites such as Ogle (Region 4) also had commercial markets for rockhead.

Despite the similarity of fishing methods between this onboard supervisor and the onboard supervisor at the Riverview landing site (Region 4), the total haul from the onboard supervisor at Riverview was significantly higher. This may be attributed to a variety of factors, foremost of which would likely be the abundance of fishes in the fishing grounds, along with sizes of vessels and respective surface areas of the seines.

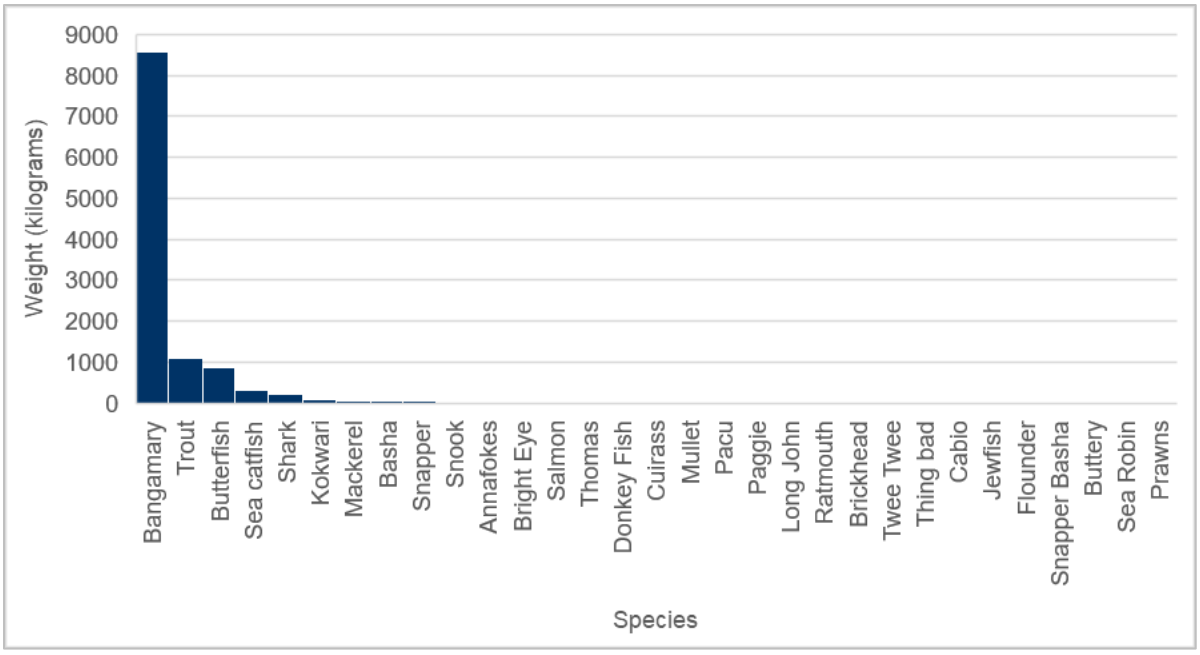

Figure T-1: Total Weight of Species Recorded by the Albion Onboard Supervisor

2.2 Fishing Areas

The main fishing area used by the onboard supervisor is 101 square kilometers. Overall, the onboard supervisor traveled within 142 square kilometers along the coast east of the Berbice River. Figure T-2 shows the fishing points in the seasons which were considered by the onboard supervisor as the peak/good season (May to September 2019) and off-peak/hard season (October 2019 to February 2020) at the outset of the study program. During the October to February period, the onboard supervisor consistently traveled farther offshore to fish than during the May to September period. The farthest distance traveled during the October to February period for fishing was 32.6 kilometers offshore. Overall, 2 kilometers was the nearest fishing point relative to the shoreline.

The fishing points underscore the changed fishing practices that were undertaken by the onboard supervisor. Specifically, greater effort was expended during the hard season, in the form of longer return

commutes between the landing site and the fishing grounds and longer soakings of the seine. These behaviors support the views held by fisherfolk that larger species like trout require more effort to catch and thus, fishing trips are generally conducted farther offshore.

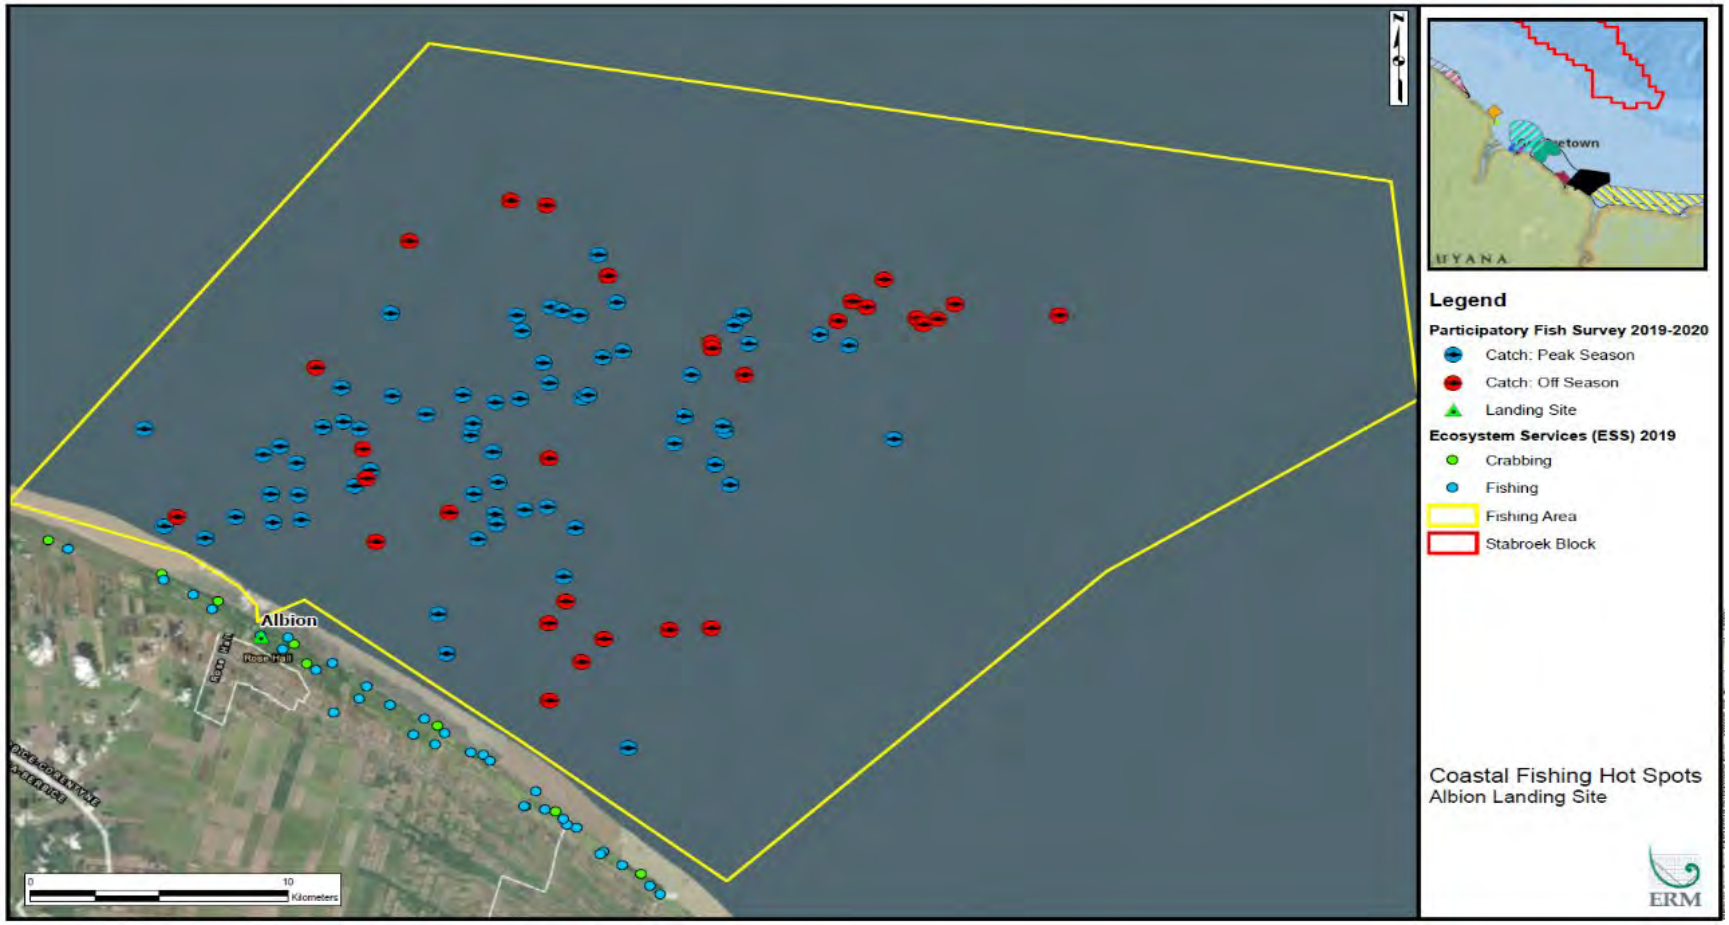

Figure T-2: Fishing Area and Fishing Points used by the Albion Onboard Supervisor

2.3 Seasonal Productivity

The onboard supervisor subscribes to the commonly-held view that fishing is most productive from May to September (the so-called “good season” that peaks in July to September) and less productive from October to March (the so-called “hard season”). It is widely believed that waters are warmer and calmer during the good season, and these conditions are more conducive to fishing. These seasons are believed to influence effort expended by fisherfolk as well as hauls per soaking of the seine and per fishing trip.

During the study, the onboard supervisor spent an average at 167 hours per month fishing but there were variations in the effort expended per fishing trip on a monthly basis as seen on Figure T-3. The onboard supervisor’s monthly effort peaked in December 2019 with 233 hours of fishing activity. The lowest effort was expended in May 2019 when 110 hours were spent fishing. As seen on Figure T-4, the greatest total hauls were recorded in October 2019 with 1,638 kilograms (3,611 pounds). The highest average weight of hauls per soaking on Figure T-5 was recorded November 2019 and February 2020 with 105 kilograms (231 pounds) in both months. This is unusual as both of these months are part of the hard season for fishing. In addition, this follows the trend reported by the onboard supervisor at the Bushlot landing site (Region 5) where the most productive months were also part of the hard season. Moreover, the lowest average weight of hauls per soaking was in June 2019, which was expected to have been one of the months with peak productivity for fishing at this landing site, with an average of 48 kilograms (106 pounds) per soak.

Seasonal variations in effort and productivity were observed as follows:

- In the May to September 2019 good season, the total weight of hauls was 5,007 kilograms (11,038 pounds) with 744 hours spent at sea. On average, soaking of the seine in this period yielded 76 kilograms (167 pounds). Within this period, the average weight of hauls declined in June from a relatively high level in May. In fact, as noted above, the average weight of hauls per soaking were the lowest in June. However, from June to September the average weight of hauls continued to rise but did not achieve the peak until the hard season. A similar trend was observed for total hauls during this season.

- In the October 2019 to February 2020 hard season, the total weight of hauls was 6,466 kilograms (14,255 pounds) with 929 hours spent at sea. On average, soaking of the seine in this period yielded 89 kilograms (196 pounds). In particular, total hauls and average productivity per soaking were consistently high in October to November after which there was a sharp decline in December, ultimately ending with an uptick in January to February. Compared to the May to September 2019 season, the October to February 2020 period had greater total hauls and more productive soakings of the seine. However, the total effort expended for fishing was higher than in the good season.

By comparison, seasonal trends in the wet and dry season were as follows:

- In August to October 2019, the primary dry season, the total weight of hauls was 4,063 kilograms (8,957 pounds) with 519 hours spent at sea. On average, soaking of the seine during this period yielded 92 kilograms (203 pounds).

- In May to July 2019, the primary wet season, the total weight of hauls was 2,582 kilograms (5,692 pounds) with 423 hours spent at sea. On average, soaking of the seine during this period yielded 67 kilograms (148 pounds).

- In February 2020, one of the months of the secondary dry season, the total weight of hauls was 1,365 kilograms (3,009 pounds) with 166 hours spent at sea. On average, soaking of the seine in this

period yielded 105 kilograms (231 pounds). Data collection at this site did not commence until May 2019 and therefore, there will be a data gap for March 2020 and April 2019 to complete this season.

- In November 2019 to January 2020, the secondary wet season, the total weight of hauls was 3,462 kilograms (7,632 pounds) with 566 hours spent at sea. On average, soaking of the seine during this period yielded 82 kilograms (181 pounds).

Based on the data seen above, the October 2019 to February 2020 period was more productive as both the average weight of hauls per soaking and total hauls increased from May to September. However, the total effort expended also increased. In fact, the increases of total haul and total effort were proportionate, with each increasing by 12 percent. This is unusual as greater total effort typically occurred and peaked during the season with the lowest productivity at other landing sites such as Windsor Forest and La Grange (Region 3), Ogle and Riverview (Region 4), and Bushlot and Rosignol (Region 5). In fact, at these sites, greater total haul is associated with lower effort because during the good season, the average weight of hauls per soaking is higher and fisherfolk achieve the target weight of hauls more quickly.

In response to this unusual trend, the onboard supervisor indicated that since the October 2019 to February 2020 period is considered the hard season, the crew was traveling to fishing grounds farther offshore and thereby expended greater effort to access fishing grounds. Accessing fishing grounds farther offshore was also part of a deliberate change in practice to target greater hauls of trout from which income could be earned both for the flesh of the fish and the glue (swim bladders), which are sold separately. Finally, the onboard supervisor indicated that demand for fish is higher during the Christmas and New Year holiday season and this directly influenced the decision to expend greater effort fishing in December 2019 and January 2020.

However, at the Albion landing site, similar to other landing sites in the study, greater effort is not a reliable indicator of greater total haul. As seen from November to December 2019, the onboard supervisor significantly increased effort, but total hauls remained relatively unchanged because the average weight of hauls per soaking also declined. More specifically, when soakings are not as productive, a disproportionate level of effort is required to achieve total hauls comparable to months or seasons when soakings of the seine are more productive. The onboard supervisor indicated that over the last 2 years, trends with hauls during the peak and off-peak season have been inconsistent and did not follow the anticipated seasonal productivity. Additional data are required to ascertain this trend of productivity for this onboard supervisor, particularly given the deliberate change in fishing practices and target species during the hard season. Additional data would also further determine whether the experience is similar for other fisherfolk at the Albion landing site.

Based on the supervisor's experience and the total-haul to total-effort ratio in October 2019 to February 2010, it can be concluded that there is no clearly defined good and hard season for the onboard supervisor's fishing practice. As a result, there are also no clear trends in productivity based on climatic seasonality. For example, the most productive hauls occurred in the dry seasons (August to October 2019 and February 2020) but the greatest total productivity was observed in the secondary wet and dry seasons.

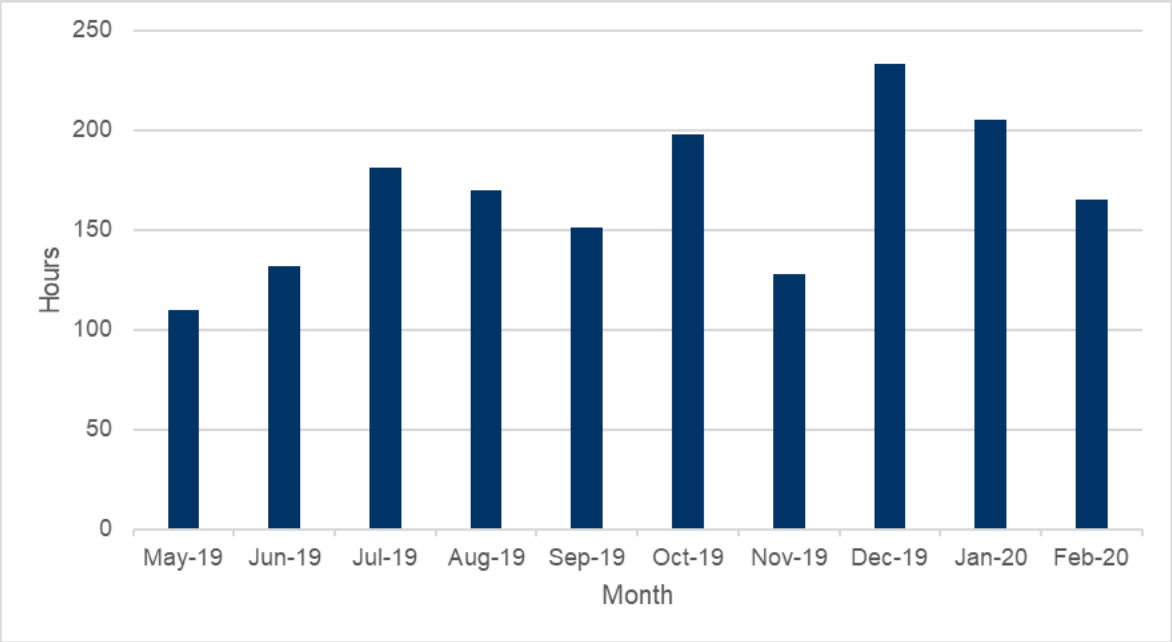

Figure T-3: Total Monthly Fishing Effort Recorded by the Albion Onboard Supervisor

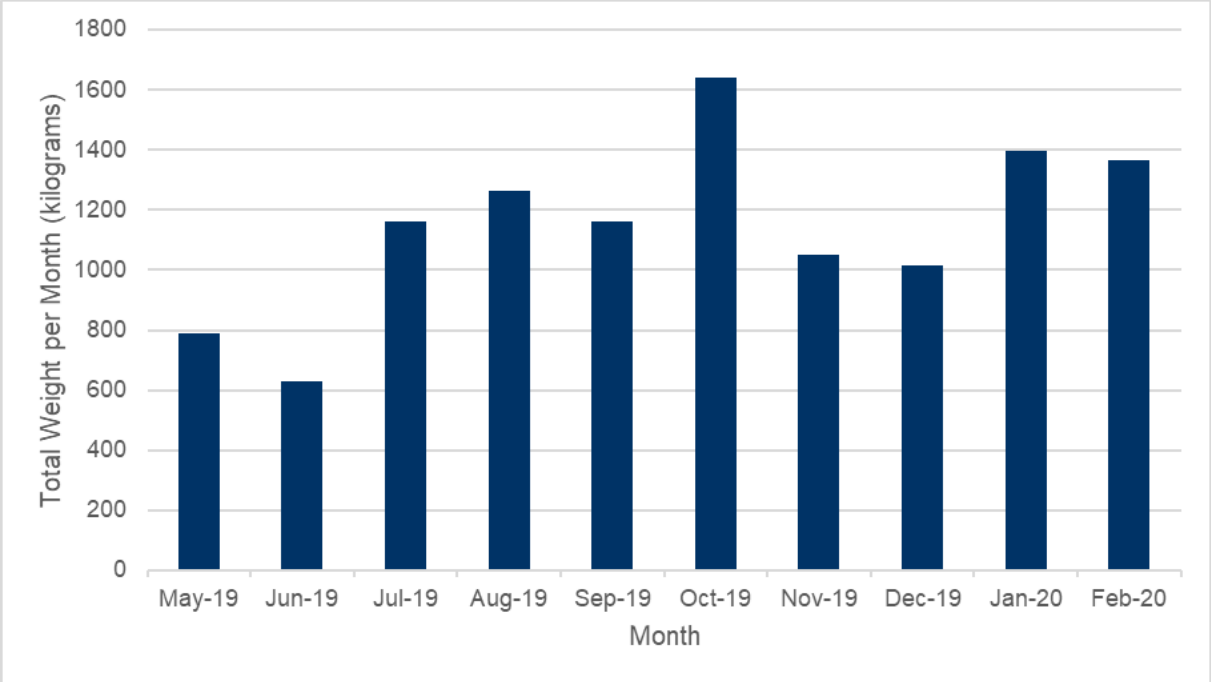

Figure T-4: Total Monthly Weight Recorded by the Albion Onboard Supervisor

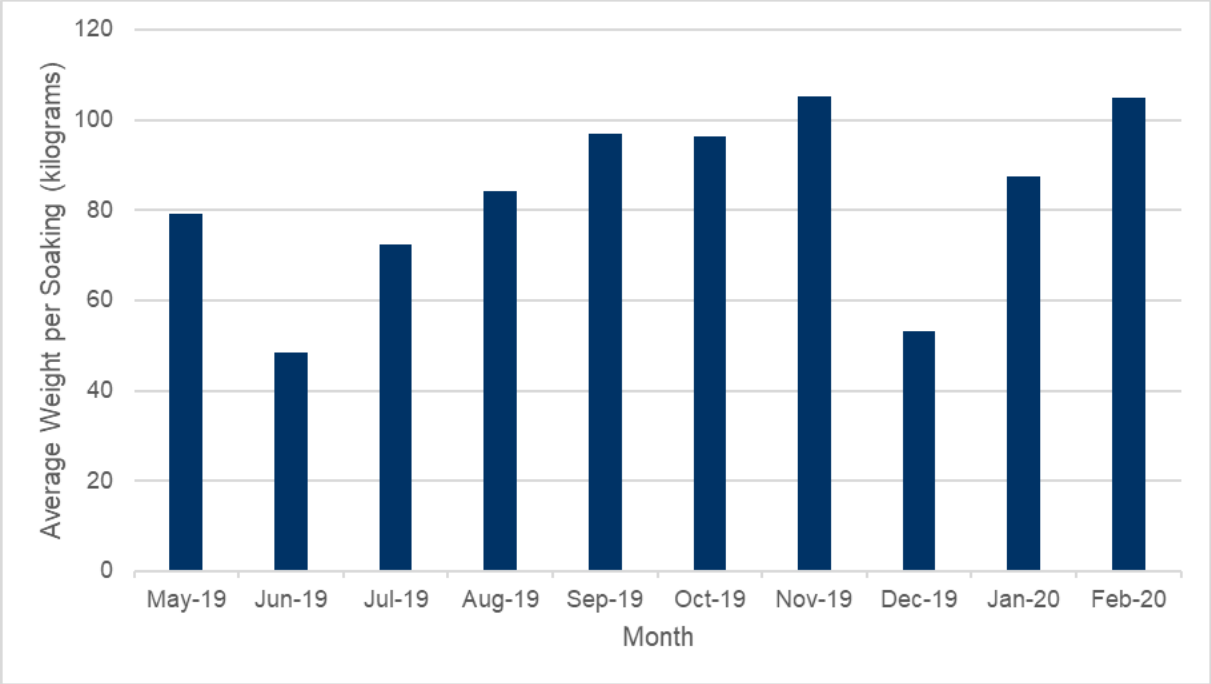

Figure T-5: Average Weight per Soaking Recorded by the Albion Onboard Supervisor

2.4 Biometrics

The onboard supervisor measured the lengths and weights of representatives of 28 species and the annual average lengths and weights of these fishes are shown on Figure T-6. Based on the measurements taken by the onboard supervisor, most of the fishes caught were sexually mature. In addition, target species such as bangamary, butterfish, and trout generally had achieved maturity with annual average lengths 31, 30, and 69 centimeters, respectively. However, the jewfish and sharks were juveniles.

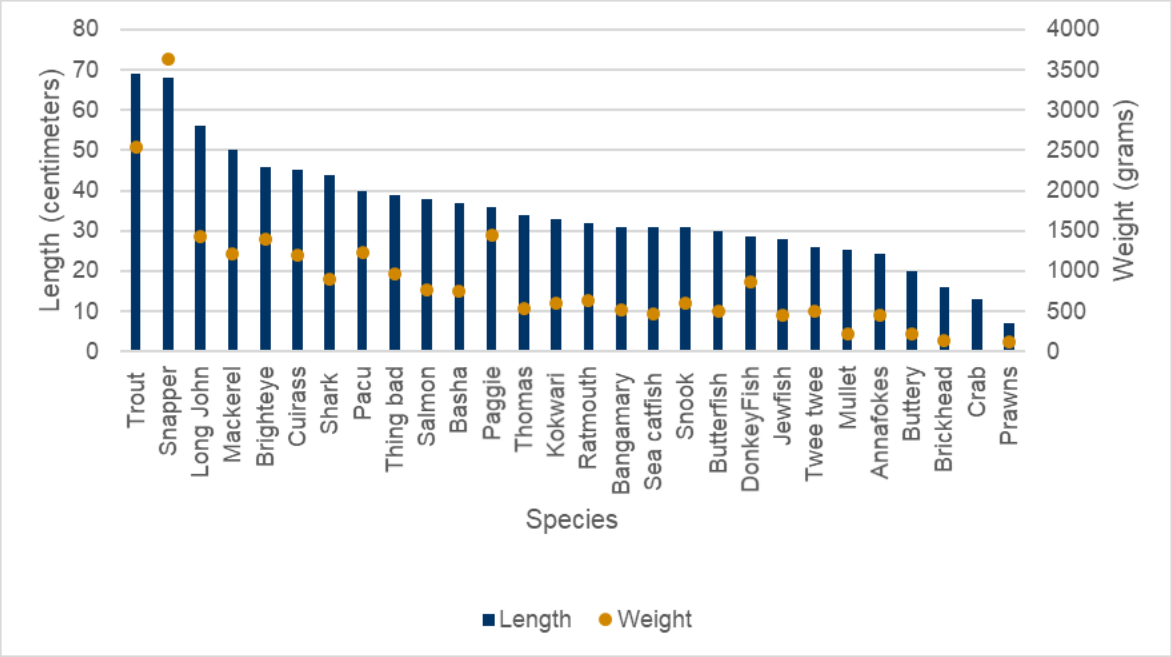

Figure T-6: Average Length and Weight of Fishes Caught by the Albion Onboard Supervisor

The monthly average lengths and weights of the four most abundant species caught are presented on Figure T-7. The average annual lengths of the most abundant species caught was greater than 30 centimeters indicating that these species have matured, similar to the trends observed at the Riverview landing site (Region 4) where the onboard supervisor also uses the bangamary seine for fishing.

Bangamary achieved peak sizes in October 2019 while the largest trout, butterfish, and sea catfish were caught in September, June, and July 2019. This may be related to large fishes coming closer to shore for both feeding and spawning. At the Riverview landing site, peak sizes of these four fishes were recorded in May to June 2019 and peak productivity occurred in July. At the Albion landing site, the largest fishes of the two most abundant species caught were in September to October which immediately preceded the most productive month of November 2019. Additional data would be needed to further examine this relationship.

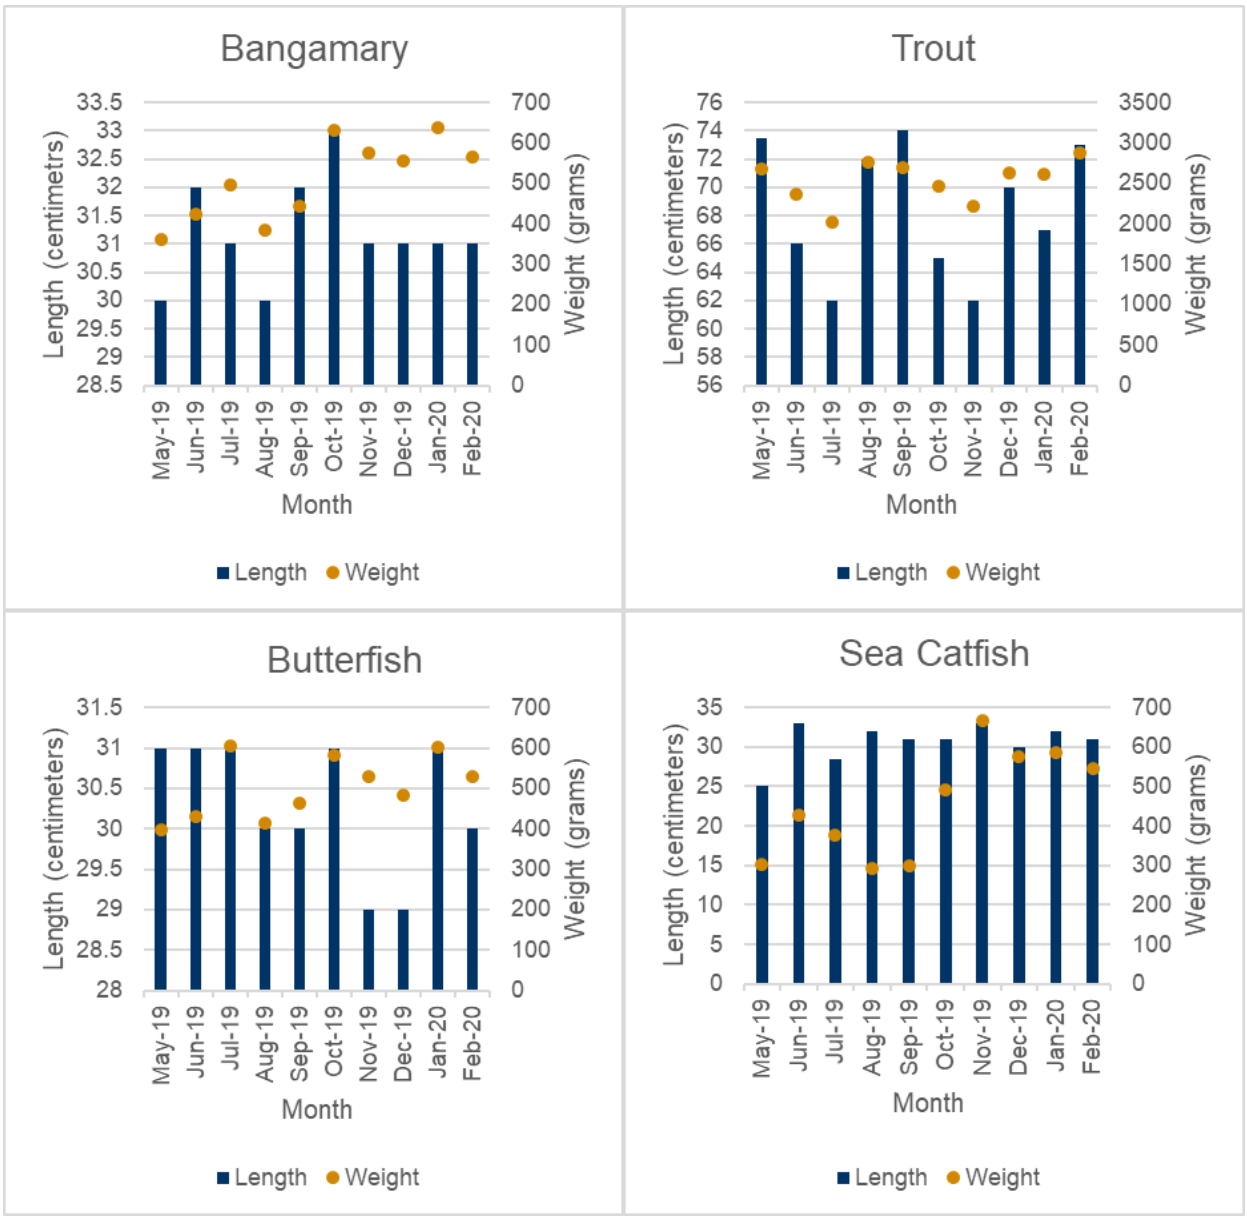

Figure T-7: Average Lengths and Weights of the Most Abundant Species Caught

3 QA/QC DATA

As part of the QA/QC exercise from 7 to 11 October 2019, a GoPro camera was mounted on the onboard supervisor's vessel. Several key observations were made from the video monitoring of the 12-hour fishing trip:

- The seas were noticeably rough. Due to the size of the swells, this indicated that they were at relatively deeper waters than seen during the other videos on fishing activity.
- The vessel uses a bangamary seine and, as expected, bangamary is the primary target species, constituting the main percentage of the total haul. However, prior to the videoed trip, the onboard supervisor and other fisherfolk at the landing site indicated that butterfish was being caught in greater

abundance. This trend in catch composition was observed in the trip that was assessed (Figure T-8) and is supported by video evidence.

- The seines were soaked for 3 hours. During this period, the crew tried to sleep, but were unable due to rough sea conditions.

During the January 2020 QA/QC, a haul from the onboard supervisor's vessel was assessed. The haul from this trip was 191 kilograms (421 pounds) and this was significantly higher than the 87 kilograms (192 pounds) average hauls during this month. However, the supervisor acknowledged that the haul was uncharacteristically large. The supervisor also said that although bangamary seines were still being used, the fishing practices had been changed to target trout because of potential additional earnings from the sale of the glue (swim bladders). As a result, fishing trips were occurring even farther offshore. In addition, trout accounted for 94 percent of the haul, which is not a common catch composition from bangamary seines.

The study coordinator also took biometric measurements of the same fishes that were measured by the onboard supervisor, and no significant data deviations were observed. For example, trout measured during the QA/QC exercise averaged 59 centimeters compared to average monthly lengths of 67 centimeters based on the data collected by the onboard supervisor (see Figure T-9). Similarly, bangamary average length measured during the QA/QC exercise was 31 centimeters compared to average monthly lengths of 29 centimeters based on the data collected by the onboard supervisor. Overall, the study coordinator was satisfied that the onboard supervisor was accurately recording the commercial species caught and following guidance in taking biometric measurements.

Figure T-9: Lengths and Weights of Fishes Measured during the QA/QC Exercises

APPENDIX U COMPLEX 66 (REGION 6)

1 LANDING SITE OVERVIEW

Complex 66 is the largest landing site for artisanal fishing vessels in Region 6 and one of the largest landing sites in Guyana. The site is also managed by a cooperative called the Upper Corentyne Fishermen Coop Society. Approximately 140 vessels routinely operate at this landing site and more than 200 vessels during the peak fishing seasons. Vessels are fitted with outboard cruisers of 40 to 60 hp. The main gear used are drift seines with mesh sizes of 13 to 20 centimeters (5 to 8 inches). Vessels at this landing site fish along the Suriname and Guyana coast at 30 meters of depth and 34 kilometers offshore. These vessels spend 10 to 16 days at sea per trip with soak times of 6 to 12 hours.

Fisherfolk indicated that obtaining licenses for fishing in Surinamese waters is one of the main challenges they encounter. Fisherfolk also shared the concerns they have for their safety because of alleged pirate attacks while at sea. In addition, fisherfolk indicated that improper disposal of cat-gut seines are contributing to the reduction of fish stocks. These seines are made of plastics and do not degrade in water. Improper disposal of these seines at sea continuously entangle fishes, which would subsequently die in them. The main species targeted at this site are snapper, trout, and gillbacker.

Total haul varies from 100 to 1,000 kilograms (220 to 2,200 pounds), depending on the duration of the trip and season. Prices range from $500 to 800 GYD ($2.4 to 3.8 USD) per kilogram depending on the species being sold. A daily pre-dawn bustling market is at this landing site where fishes are auctioned to vendors and local customers visiting the landing site. The main expense is fuel with extended fishing trips costing approximately $240,000 GYD ($1,148 USD).

2 ONBOARD SUPERVISOR RESULTS

The onboard supervisor who participated in this study uses drift seines with mesh sizes of 19 centimeters (7.5 inches) to target snapper. This is likely the target species because this landing site is one of the major supply sites for the glue (swim bladders) of snapper and trout. The onboard supervisor typically has fishing trips lasting 10 to 15 days. The vessel has a haul capacity of 4,545 kilograms (10,020 pounds) and is powered by a 60 hp engine. Each fishing trip required a three-member crew. The main expenses per fishing trip are for rations for the crew, fuel, and ice for the preservation of the haul. Due to the prolonged periods spent at sea, the supervisor also guts the fishes before icing them during the fishing trip. When gutting fish, the supervisor harvests the glue from the snapper and trout, as well as any eggs from female fishes in particularly gillbacker, snapper, and trout. These are iced and sold separately from the flesh of the fishes upon return to the landing site. Like most other vessels at this landing site, the supervisor also fishes in Surinamese waters but hauls are sold at the market at the Complex 66 landing site when the vessel returns to shore.

During the reporting period, the onboard supervisor did not experience any challenges that significantly affected fishing activities. However, data were not collected in December 2019 because the onboard supervisor decided to stay onshore to spend time with family.

2.1 Target Species and Diversity

The total weights of combined hauls from the onboard supervisor’s vessel over the period April 2019 to February 2020 was 5,588 kilograms (12,319 kilograms) using a total effort of 3,168 hours. Snapper was the most abundant species caught by a significant margin (see Figure U-1). In total, 3,621 kilograms (7,983 pounds) of snapper were caught representing 65 percent of the total haul. Trout was the second most abundant species caught with a total weight of 1,197 kilograms (2,638 pounds) accounting for 21 percent of the total catch. Cuirass and bangamary were the third and fourth most abundant species

caught representing 7 percent and 2 percent of the total haul respectively. A catch composition with snapper, trout, and cuirass as the three most abundant species caught were observed at the Rosignol landing site (Region 5) where drift seines with mesh sizes of 19 centimeters (7.5 inches) were the main type of gear used. Similarly, snapper and trout as the two most abundant species caught were also observed at the Charity landing site (Region 2) where drift seines with mesh sizes of 18 centimeters (7 inches) were used. Cuirass was the most abundant species caught at the Bushlot landing site (Region 5) where the main type of gear used by the onboard supervisor was drift seines with mesh sizes of 18 centimeters (7 inches).

Overall, 15 species were caught, 10 of which were caught in low quantities of 100 kilograms (220 pounds) or lower. Due to the relatively large mesh sizes of the seine, bycatch is limited. The bycatch recorded by the onboard supervisor primarily comprises sea catfish and bangamary, and these are commercially viable if brought back to shore. However, discarding commercially viable and generally mature fishes as bycatch is a deliberate action intended to increase the capacity of the vessel to haul high-value target species like snapper and trout.

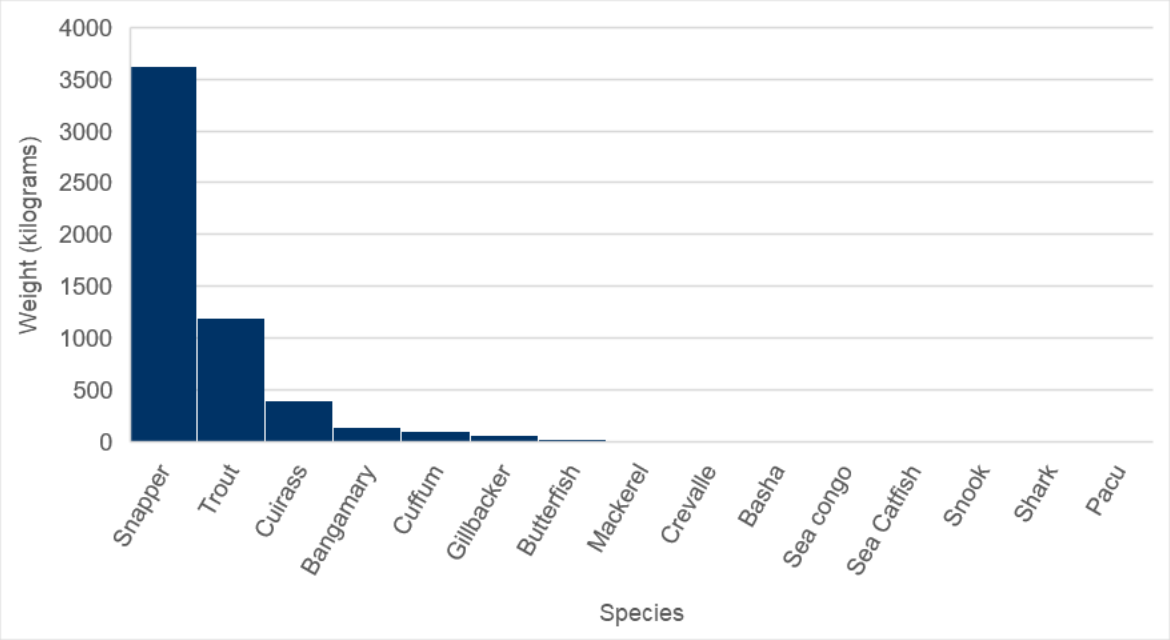

Figure U-1: Total Weight of Species Recorded by the Complex 66 Onboard Supervisor

2.2 Fishing Areas

The onboard supervisor at the Complex 66 landing site had the largest traveling range of any of the onboard supervisors with 7,003 square kilometers (see Figure U-2). Due to the expanse of the traveling range, fishing points were observed around main clusters, all of which were located around the mouths of rivers:

1. The largest cluster covered an area of 1,132 square kilometers with fishing points at the mouth of the Corentyne River. Most of the fishing in this cluster occurred during the peak season. The fishing grounds in this cluster were also used by the onboard supervisor from the Rosignol landing site (Region 5).

2. The second largest cluster covered an area of 603 square kilometers with fishing points around the mouth of the Coppename River in Suriname. Most of the fishing in this cluster occurred during the hard season. The fishing grounds in this cluster were also used by the onboard supervisor from the Rosignol landing site (Region 5) but only during the good seasons.

3. The smallest cluster covers an area of 149 square kilometers with only a few fishing points being marked outside the Suriname River. These fishing grounds were located approximately 209 kilometers from the landing site, the farthest the onboard supervisor traveled to access the fishing grounds. Fishing was only conducted at these fishing points during the good/peak season. The onboard supervisor explained that these fishing grounds are only rarely used and were part of exploratory fishing activities of a single fishing trip.

Generally, the onboard supervisor's vessel remained relatively close to the shore in both the good and hard seasons. The main seasonal difference between the peak and hard seasons in terms of vessel movements was use of the Suriname River, which only occurred during the peak season. Waters are reportedly calmer during the good season and therefore, more conducive to traversing greater distances. However, greater effort was expended by the supervisor during the off-peak season indicating that there were longer fishing trips, likely due to less productivity per haul, along with the rough seas which made travel to and from the landing more difficult.

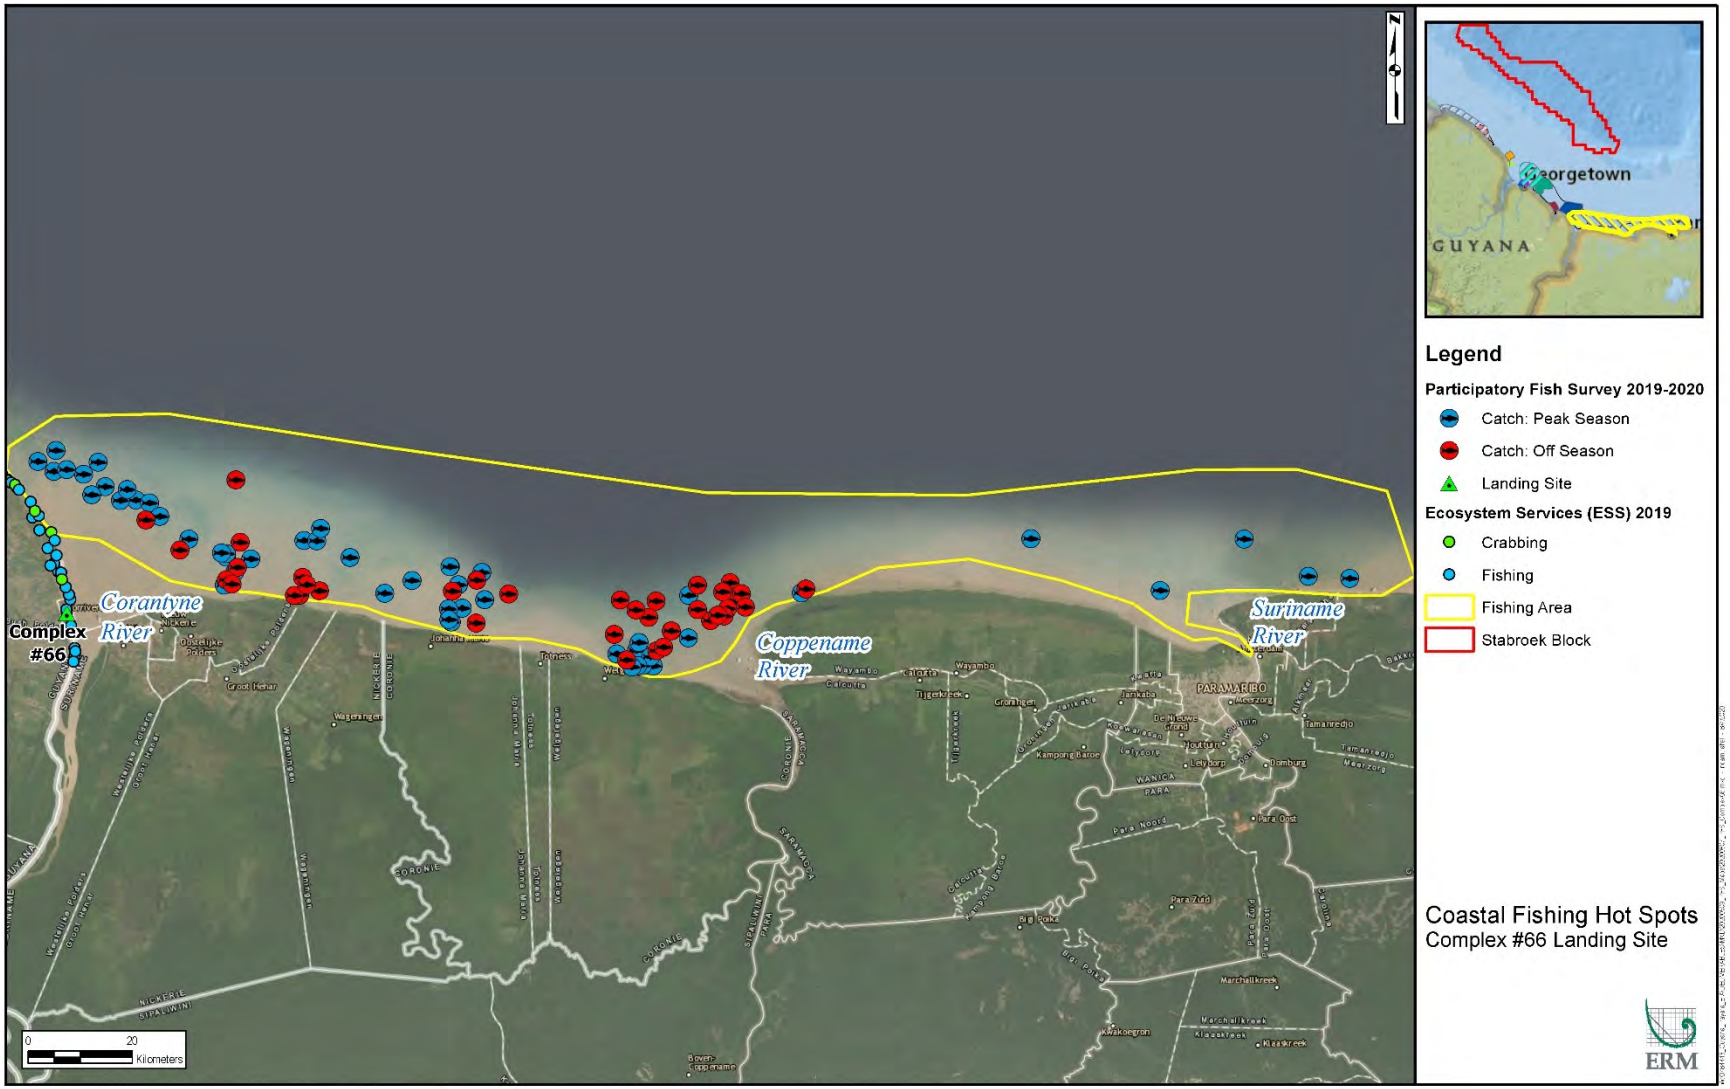

Figure U-2: Fishing Area and Fishing Points used by the Complex 66 Onboard Supervisor

2.3 Seasonal Productivity

The onboard supervisor subscribes to the commonly-held view that fishing is most productive from May to September (the so-called “good season” that peaks in July to September) and less productive from October to March (the so-called “hard season”). It is widely believed that waters are warmer and calmer during the good season, and these conditions are more conducive to fishing. These seasons are believed to influence effort expended by fisherfolk as well as hauls per soaking of the seine and per fishing trip.

During the data collection period, the onboard supervisor spent an average of 310 hours per month fishing, but there were variations in the effort expended per fishing trip on a monthly basis as seen on Figure U-3. The greatest effort was observed in July 2019 when 456 hours were spent fishing. Although 72 hours were expended in April 2019, data collection did not begin until April 27 and as such, there is no comparable full monthly data pool for this month. In July, the onboard supervisor indicated that conditions were favorable and allowed fishing trips to last for longer periods. High levels of effort were also observed during the hard season months of October 2019 and January or February 2020. Increasing effort during the hard season is a common practice among fisherfolk to increase total hauls when hauls per soaking are relatively low. As seen on Figure U-4, the greatest total hauls were recorded in October 2019 with 873 kilograms (1,925 pounds). As seen on Figure U-5, the highest average weight of hauls per soaking was recorded in May 2019 with 73 kilograms (160 pounds).

Seasonal variations in effort and productivity were observed as follows:

- In the May to September 2019 good season, the total weight of hauls was 3,034 kilograms (6,689 pounds) with 1,656 hours spent at sea. On average, soaking of the seine during this period yielded 46 kilograms (101 pounds). This season saw the highest average weight of hauls per soaking and greatest effort over the data collection period. The most productive hauls were recorded in May 2019 and the greatest effort was expended in July 2019.

- In the October 2019 to February 2020 hard season, the total weight of hauls was 2,442 kilograms (5,384 pounds) with 1,368 hours spent at sea. On average, soaking of the seine during this period yielded 44 kilograms (97 pounds). During this season, the greatest total haul of the data collection period was recorded in October 2019 with 873 kilograms (1,925 pounds). In addition, October 2019 also saw the second highest average weight of hauls per soaking and the second greatest total effort expended. Data are not considered for April 2019 in this season because the data pool is too small.

By comparison, seasonal trends in the wet and dry season were as follows:

- In August to October 2019, which falls within the primary dry season, the total weight of hauls was 1,869 kilograms (4,120 pounds) with 1,104 hours spent at sea. On average, soaking of the seine during this period yielded 40 kilograms (88 pounds).

- In May to July 2019, which falls within the primary wet season, the total weight of hauls was 2,039 kilograms (4,495 pounds) with 960 hours spent at sea. On average, soaking of the seine in this period yielded 53 kilograms (117 pounds).

- In February 2020 and April 2019, two months of the secondary dry season, the total weight of hauls was 685 kilograms (1,510 pounds) with 504 hours spent at sea. On average, soaking of the seine during this period yielded 34 kilograms (75 pounds). Data were not retrieved for March 2020 to complete this season.

- In November 2019 and January 2020, two months of the secondary wet season, the total weight of hauls was 995 kilograms (2,194 pounds) with 528 hours spent at sea. On average, soaking of the

seine in this period yielded 46 kilograms (101 pounds). The onboard supervisor did not participate in the fishing trips in December 2019 so no data were collected.

Overall, greater productivity was observed in the May to September 2019 season. Similar to the Albion (Region 6) landing site, greater productivity was also accompanied by an increase in effort, but this may have been partially attributed to using fishing grounds located farther from the landing site thereby requiring additional travel time. Indeed, at Complex 66, total effort and total haul were both approximately 20 percent greater in May to September 2019 as compared with October 2019 to February 2020. This is similar to fishing practices at the Albion landing site where greater effort was also observed in the season with the greatest productivity. Despite higher total productivity in the May to September good season, productivity on a monthly basis was highly varied. The onboard supervisor indicated that there is typically a large variation in hauls over the good season. The owner of the vessel on which the onboard supervisor operates has suggested that downturns in other economic sectors, particularly in agriculture, has led to more persons becoming involved in fishing. Increased competition for the same shared fishing resources has caused many fisherfolk to use larger seines (seines with greater surface areas) with the intention of increasing total hauls. This fisherfolk believes that these practices have changed seasonal dynamics of productivity leading to significant seasonal variability in particular during the peak seasons when more persons are engaged in fishing activity.

Productivity was higher in the primary wet and dry seasons than during the short wet and dry seasons, with the largest hauls occurring in the wet season when fishing effort is concentrated primarily around the mouths of rivers. According to Lowe-McConnel (1962), nutrient flows are increased during the wet season and fishes are expected to be more abundant at river mouths during this season.

Based on the supervisor’s experience and the total-haul to total-effort ratio in October 2019 to February 2020, it can be concluded that there is no clearly defined good and hard season for the onboard supervisor’s fishing practice. This may signal yet another shortened peak season similar to that experienced by fisherfolk in Rosignol. Additional data are required to ascertain if this trend of productivity is typical for this onboard supervisor and to determine whether the experience is similar for other fisherfolk at this landing site.

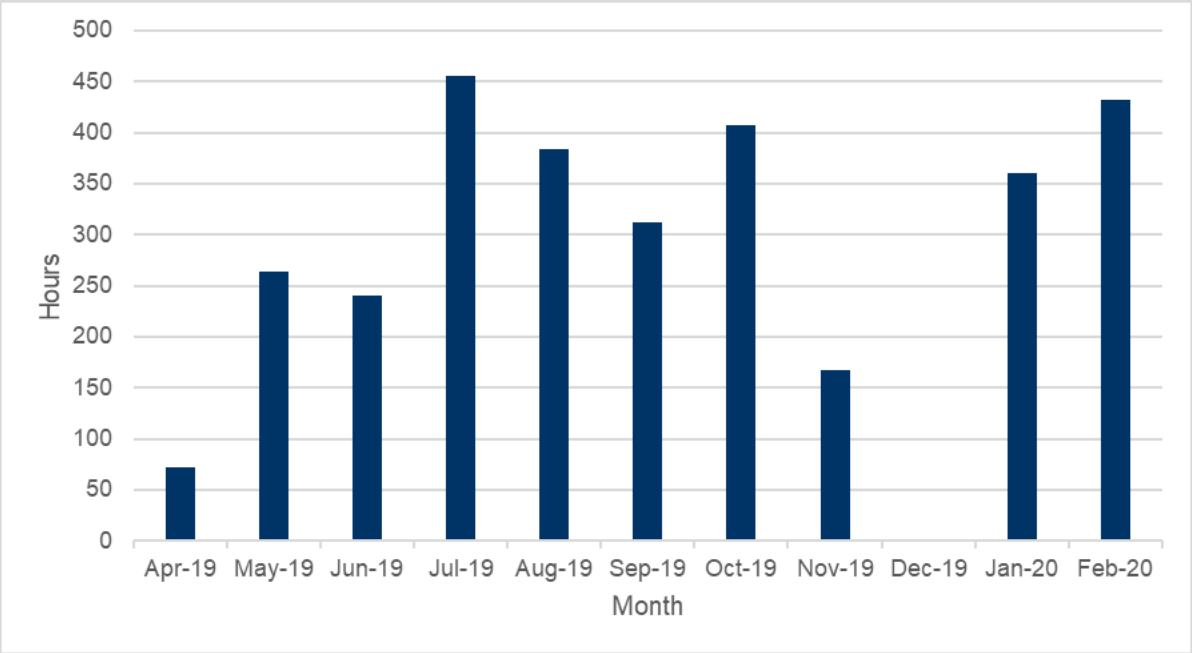

Figure U-3: Total Monthly Fishing Effort Recorded by the Complex 66 Onboard Supervisor

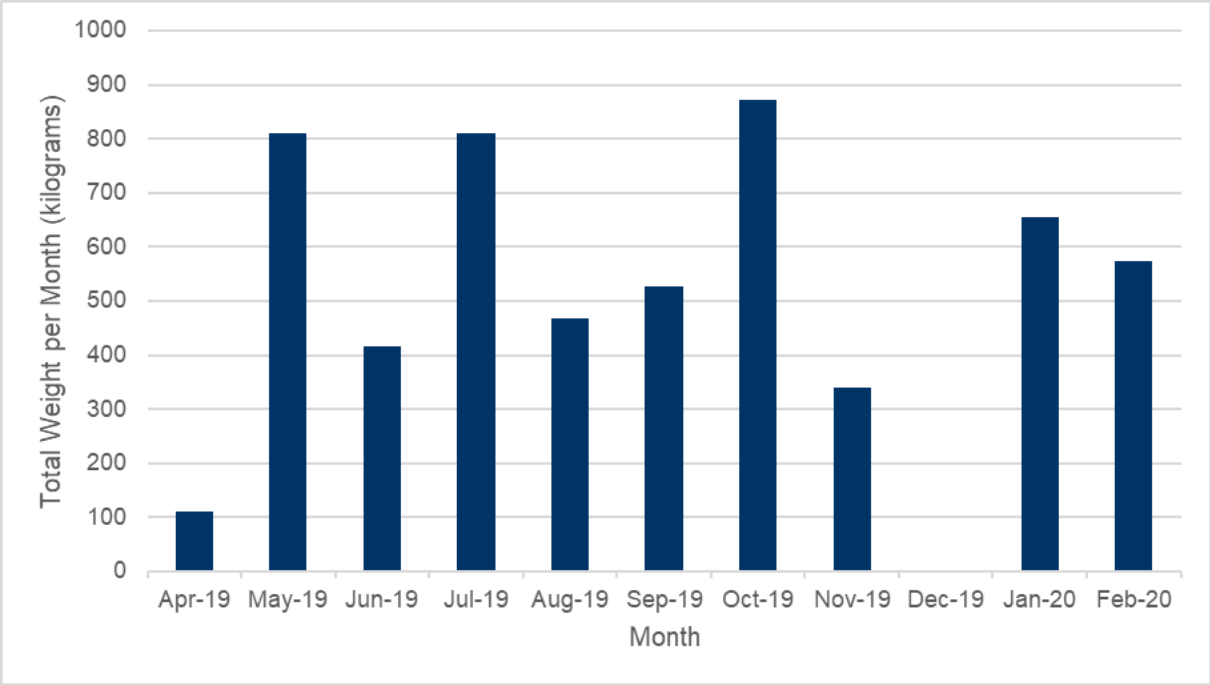

Figure U-4: Total Monthly Weight Recorded by the Complex 66 Onboard Supervisor

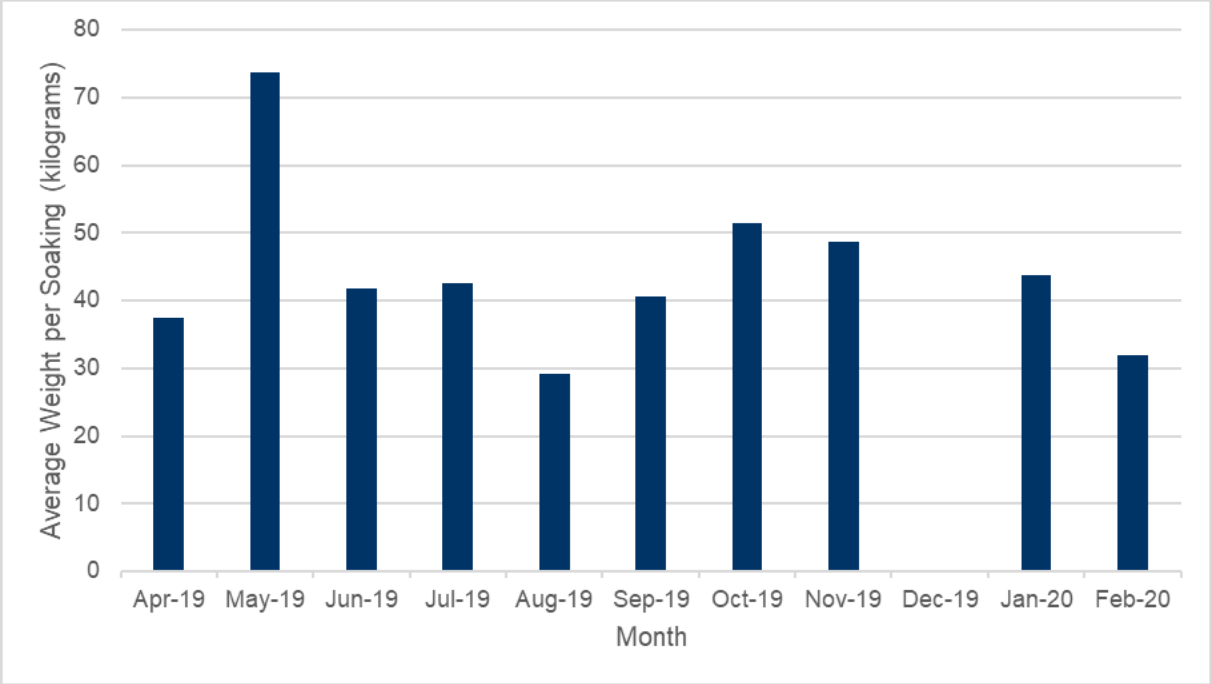

Figure U-5: Average Weight per Soaking Recorded by the Complex 66 Onboard Supervisor

2.4 Biometrics

The onboard supervisor measured the lengths and weights of representative fishes for each haul; the annual average lengths and weights of these fishes are shown on Figure U-6. Based on the measurements taken by the onboard supervisor, most of the fishes caught were sexually mature. The target species of snapper and trout had reached annual average lengths of 69 and 61 centimeters, respectively, and would be considered mature. Snook was the only species caught that did not achieve sexual maturity.

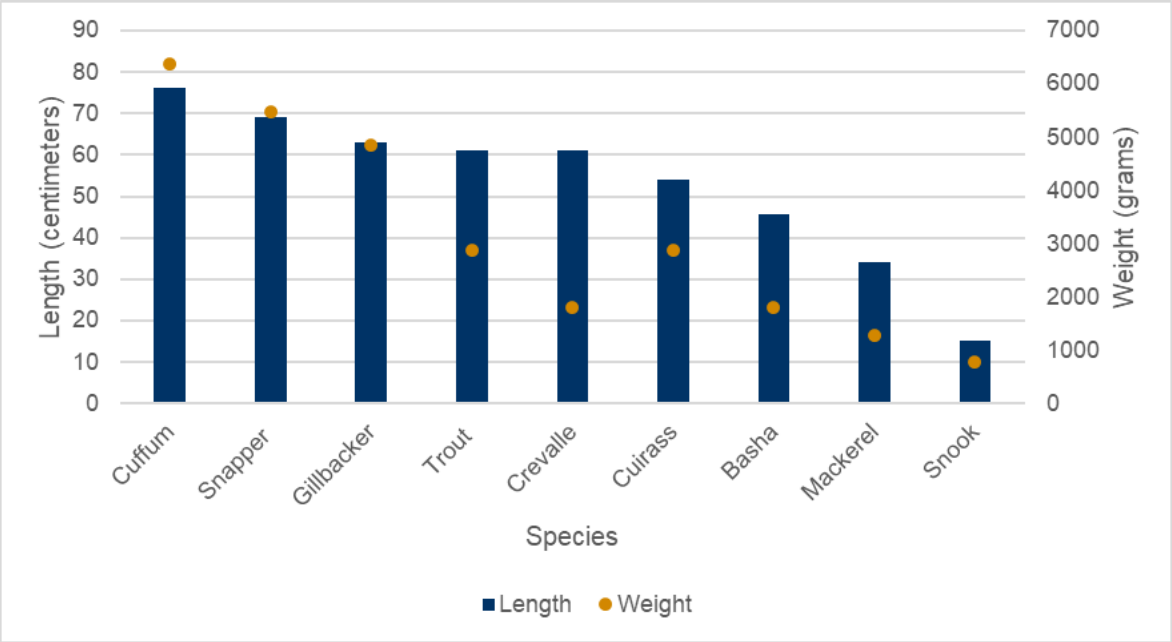

Figure U-6: Total Monthly Weight and Average Weight per Soaking of Hauls Recorded by the Complex 66 Onboard Supervisor

The monthly average lengths and weights of the two most abundant species caught are presented on Figure U-7. All of the fishes measured have reached maturity. The largest snapper and trout were caught in June and July 2019, respectively, after which there was a decline in sizes. This may have been due to more mature females with eggs coming closer to the shoreline to spawn in lagoons, estuaries, and mangroves. This trend is also seen in the data recorded at several other landing sites, like Smith's Creek, Charity, etc., where smaller fishes are caught when the spawning season ends.

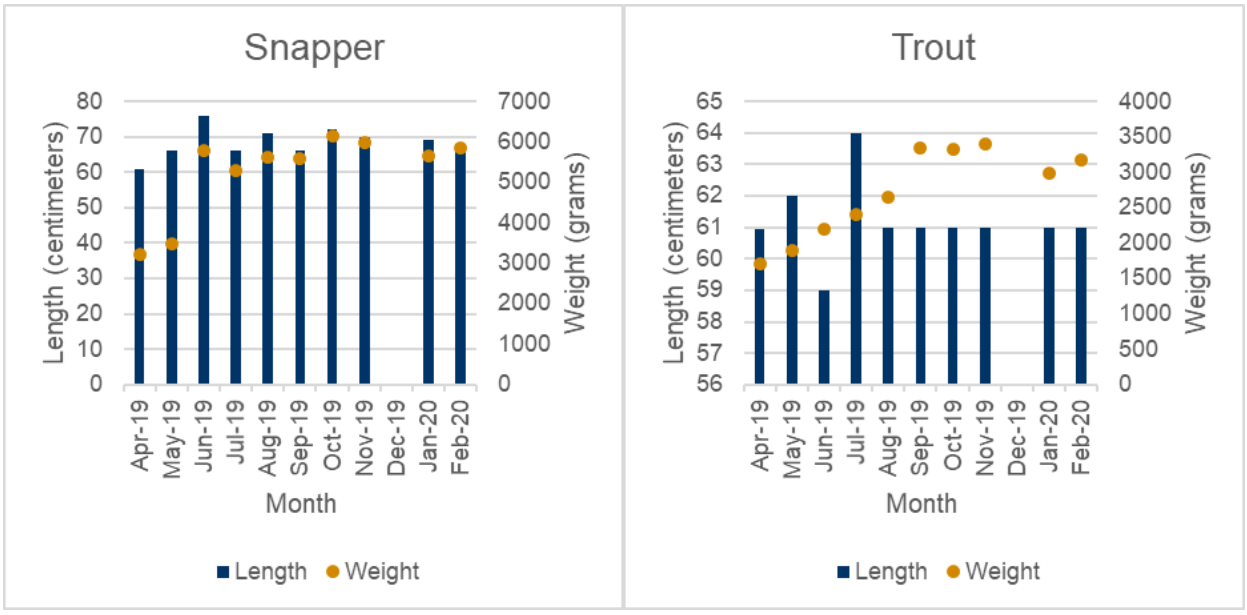

Figure U-7: Average Lengths and Weights of the Most Abundant Species Caught

3 QA/QC DATA

In October 2019, the team conducted the QA/QC exercise for one of the fishing trips conducted by the onboard supervisor. During this trip, the onboard supervisor used a drift seine with mesh sizes of 18 centimeters (7 inches). The trip lasted for 11 days and the seine was soaked 12 times. Fishing activity occurred along the Surinamese coast and the vessel was powered by a 60 hp outboard engine. The supervisor reported that the waters were rough during the fishing trip. The data collected by the study team matched the trends observed during the July to September period in terms of species diversity and composition. As expected, based on the mesh sizes of the seines used, snapper was the most abundant species caught (see Figure U-8). Species diversity was also similar to the trends reported by the onboard supervisor during the reporting period. The biometric data collected showed similar trends to those observed by the supervisor (see Figure U-8). The study coordinator also took biometric measurements of the same fishes that were measured by the onboard supervisor, and no data deviations were observed. Overall, the study coordinator was satisfied that the onboard supervisor was accurately recording the commercial species caught and following the guidance provided in taking biometric measurements.

During the QA/QC exercise in January 2020, the onboard supervisor's vessel had not landed at the site. Another vessel was assessed that also used drift seines with mesh sizes of 19 centimeters (7.5 inches) that conducted its fishing activities in 6 days with 12 soakings of the seine. The vessel, however, stayed in relatively shallow waters of 5 fathoms (9 meters/29.5 feet). This resulted in a large percentage of cuirass being caught by the fisherfolk. Due to this, it is difficult to compare hauls from these two vessels. For example, the size of a representative cuirass from the QA/QC vessel was 55 centimeters, but average monthly length based on data collected by the onboard supervisor was 61 centimeters. Similarly, the size of a representative snapper from the QA/QC vessel was 75 centimeters, but the average monthly length based on data collected by the onboard supervisor was 69 centimeters.

Acronyms and Abbreviations

Name	Description
µg/m^3	micrograms per cubic meter
BTEX	benzene, toluene, ethylbenzene, and xylenes
CO	carbon monoxide
EEPGL	Esso Exploration and Production Guyana Limited
ERM	Environmental Resources Management
H_2S	hydrogen sulfide
NA	not applicable
ND	not detected (below laboratory minimum reporting level)
NO_2	nitrogen dioxide
$PM_{2.5}$	fine particulate matter (with aerodynamic diameter of less than 2.5 micrometers)
PM_{10}	inhalable particulate matter (with aerodynamic diameter of less than 10 micrometers)
ppb	parts per billion
ppb(v)	parts per billion by volume
ppm	parts per million
SO_2	sulfur dioxide
USEPA	U.S. Environmental Protection Agency
VOC	volatile organic compound
WHO	World Health Organization

EXECUTIVE SUMMARY

Environmental Resources Management (ERM) conducted an onshore ambient air quality monitoring program at three sites in Guyana over the period of 15 August 2018 through 25 August 2019. The monitoring program was designed to characterize existing ambient air quality conditions at selected onshore locations. In the absence of applicable Guyana regulatory guidance, ERM used standard methods for selecting air pollutants to monitor, selecting monitoring sites, and establishing other program parameters. Resulting measurements have been compared to the World Health Organization's (WHO) Air Quality Guideline Values and criteria from the U.S. Environmental Protection Agency (USEPA) (guidelines).

At least 6 weeks of monitoring data were collected at each of three sites: Rose Hall Estate in New Amsterdam, Berbice; Carifesta, just off the sea wall in Georgetown; and New Guyana School, in Georgetown near the east bank of the Demerara River. Monitoring occurred during two different periods at the Carifesta site. The first took place over the period of 15 August 2018 through 4 October 2018, and the second took place over the period of 11 December 2018 through 19 March 2019. Figure 1 illustrates the locations of the three monitoring sites.

Monitored air quality parameters included inhalable and fine particulate matter (PM_{10}[1] and $PM_{2.5}$[2], respectively), sulfur dioxide (SO_2), hydrogen sulfide (H_2S), nitrogen dioxide (NO_2), carbon monoxide (CO), and selected volatile organic compounds.

At the Carifesta and New Amsterdam sites, local meteorological conditions were monitored by a third-party using equipment co-located with the air quality monitoring equipment. The meteorological data were made available to ERM for use in data validation and interpretation. At the New Guyana School site, ERM operated a tripod-mounted instrument to monitor local wind speed and wind direction.

In general, measured gaseous pollutant concentrations were quite low in absolute terms, as well as in comparison to applicable guidelines. Particulate matter concentrations (both PM_{10} and $PM_{2.5}$) were near or exceeded applicable guidelines at all three monitoring sites. The only measured exceedance of a gaseous pollutant criterion was for 24-hour average benzene levels at the Carifesta monitoring site.

Tables 1 through 4 summarize the ambient air quality measurements during both monitoring periods at Carifesta (designated as "Carifesta #1" and "Carifesta #2"), the monitoring period at New Amsterdam, and the monitoring period at New Guyana School, and compares them to applicable guidelines. The tables summarize the measured concentrations for each of the pollutants / averaging periods for which a guideline value is provided by the WHO or USEPA. Note that some of the guidelines are meant to be compared to a statistical value (e.g., the 98th percentile value for 1-hour NO_2, the 99th percentile value for 1-hour SO_2). For the purpose of Tables 1 through 4, the maximum value from the appropriate averaging period is presented. These values are directly comparable to the guidelines that are intended to be compared to maximum values (e.g., 1-hour WHO value for NO_2, 1-hour and 8-hour WHO values for CO), but are higher than the values that are intended to be compared to other guidelines that have a statistical basis.

[1] Particulate matter with aerodynamic diameter of less than 10 micrometers

[2] Particulate matter with aerodynamic diameter of less than 2.5 micrometers

PM_{10}, and to a lesser extent $PM_{2.5}$, is generated by physical operations. It is likely that the elevated concentrations measured at all three sites were influenced by vehicle traffic (engine emissions, rubber tire dust, resuspended road dust) and open burning. The Carifesta site may have also received sea salt inputs due to its proximity to the coast. The sources of New Amsterdam PM_{10} ambient air impacts likely included agricultural emission sources (tilling, harvesting, and residue burning). At New Guyana School, the sources of PM_{10} ambient air impacts likely included agricultural emission sources, as well as vehicle emissions.

In most cases, the primary source of $PM_{2.5}$ is atmospheric chemical reaction of precursor gases that forms fine particles. Common precursor gases are SO_2 and NO_2 from fuel combustion, as well as ammonia from livestock operations. Combustion emissions from vehicle engines and open burning are probably also $PM_{2.5}$ emission sources impacting the three monitoring sites.

With respect to PM_{10} and $PM_{2.5}$, the comparison between the full monitoring period averages and the WHO and USEPA annual average guideline values should be considered indicative, rather than directly comparable, as the monitoring durations at each of the three sites were less than 365 days (between 50 and 141 days). The nature of atmospheric dispersion is such that average values generally decrease as the averaging period increases. Additionally, the measured maximum 24-hour average PM_{10} and $PM_{2.5}$ values cannot be directly compared with the USEPA and WHO guideline values since those guidelines are intended for comparison to statistical values (i.e., not the single highest average values), which would be lower than the highest average values.

The monitoring results for CO, NO_2, H_2S, and SO_2 were all below the WHO and USEPA guideline values. The low concentrations limit the extent to which NO_2 or SO_2 would be likely to promote ozone or secondary $PM_{2.5}$ formation.

The only measured exceedance of a gaseous pollutant criterion was the 24-hour average benzene levels at the Carifesta monitoring site. At Carifesta, the maximum 24-hour average was significantly higher than the 24-hour USEPA guideline value. The measured maximum 24-hour average value includes a single 6-minute sample that registered well above the calibration range of the analyzer. While this anomalous measurement is considered to be an outlier, it was not invalidated since all quality control parameters were within tolerance. Even if the outlier value is excluded, the maximum 24-hour average would still have exceeded the guideline value by more than 50 percent at the Carifesta site. Motor vehicle emissions may have been responsible for the measured values, since there are no obvious nearby stationary benzene emission sources upwind of the Carifesta site. The Carifesta site is situated between two roadways that are often busy and sometimes congested. The sample inlet was located 34 meters (111.5 feet) from Carifesta Road and 69 meters (226.4 feet) from Seawall Public Road—making vehicle emissions a likely source. At the New Amsterdam and the New Guyana School monitoring sites, the maximum 24-hour average benzene measurements were significantly lower than the USEPA guideline value.

1. AIR MONITORING PROGRAM DESCRIPTION

Environmental Resources Management (ERM) conducted an onshore ambient air quality monitoring program on behalf of Esso Exploration and Production Guyana Limited (EEPGL) over the period of 15 August 2018 through 25 August 2019 at three sites in Guyana: Rose Hall Estate in New Amsterdam, Berbice (the "New Amsterdam" site); Carifesta, just off the sea wall in Georgetown (the "Carifesta" site); and New Guyana School, also in Georgetown, near the east bank of the Demerara River (the "New Guyana School" site).

1.1. Monitored Air Quality Parameters

The monitored air pollutants included in the program were:

- Particulate matter—two size ranges:
  - PM_{10} (inhalable particulate matter with aerodynamic diameter of less than 10 micrometers)
  - $PM_{2.5}$ (fine particulate matter with aerodynamic diameter of less than 2.5 micrometers)
- Carbon monoxide (CO)
- Sulfur dioxide (SO_2)
- Hydrogen sulfide (H_2S)
- Nitrogen dioxide (NO_2)
- Selected volatile organic compounds (VOCs)[3]:
  - Benzene
  - Toluene
  - Ethylbenzene
  - Xylenes

Guyana has not established specific ambient air quality standards; therefore, the guidelines used for reference in this assessment were those established by the World Health Organization (WHO) in *WHO Global Air Quality Guidelines: Particulate Matter (PM2.5 and PM10), Ozone, Nitrogen Dioxide, Sulfur Dioxide and Carbon Monoxide* (WHO 2021), except for toluene, CO, and H_2S, for which WHO guidelines were published in WHO's *Air Quality Guidelines for Europe, 2nd edition, 2000* (WHO 2000). Since ozone is a secondary pollutant not directly emitted by industrial sources, it was not included in the suite of monitored parameters. While no WHO guidelines have been published for benzene, ethylbenzene, or xylenes, criteria for these species have been established by the U.S. Environmental Protection Agency (USEPA) and these were used for the assessment of results (USEPA 2019c).

1.2. Monitoring Sites

The monitoring sites were selected by EEPGL and ERM based on the sites' ability to characterize existing ambient air quality in areas upwind and downwind of urban Georgetown (where urban emission levels are anticipated to be highest).

Historical climatological data (such as prevailing wind patterns) and USEPA siting criteria were also considered in selecting specific sites. Finally, site accessibility and availability of power supply were factored into the final site selection.

[3] As noted in the report, during the 12 April through 27 June 2019 monitoring period, an electrochemical sensor was employed at the New Guyana School site to measure total VOCs when the gas chromatograph that normally measures speciated BTEX was out of service. While this sensor does not speciate VOCs, the total VOC measurements represent a maximum limit on the sum of the BTEX compounds' concentrations. The sensor data was supplemented by several evacuated canister ("Summa") samples that collected whole air for subsequent laboratory analysis. These analyses provided speciated BTEX values.

The Carifesta monitoring site was established adjacent to Guyana Telephone & Telegraph's Carifesta Avenue location. See Figure 2 for a map of the Carifesta monitoring site. The New Amsterdam monitoring site was established at Rose Hall Estate, adjacent to the Rose Hall Sugar Factory in New Amsterdam, Berbice, as shown on Figure 3.

The New Guyana School monitoring site was established in Georgetown, on the school's property, near the east bank of the Demerara River. Figure 4 illustrates the location of this site.

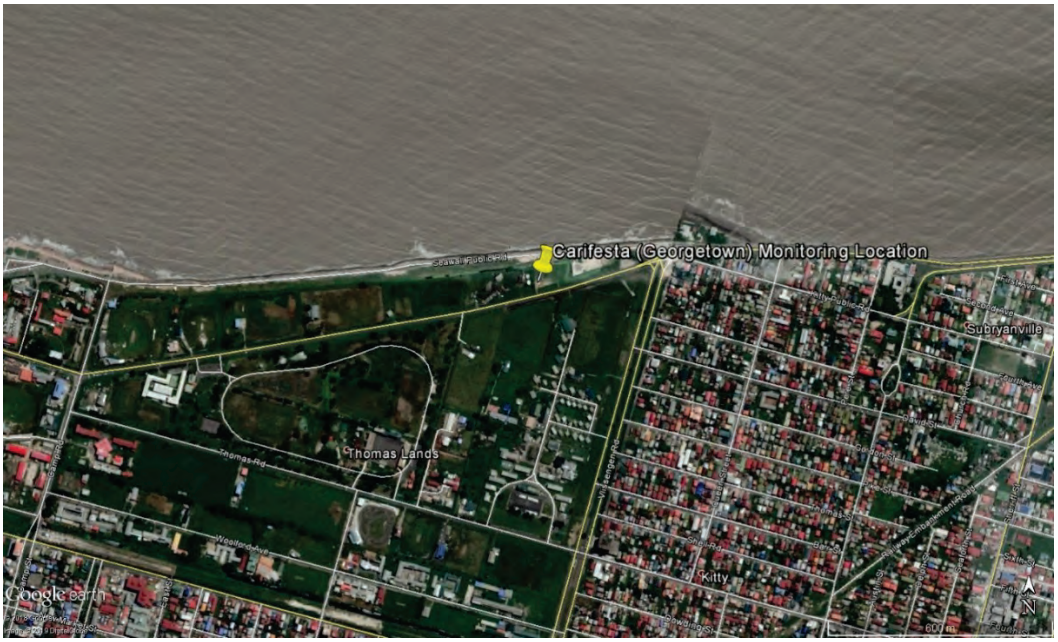

Figure 2: Carifesta (Georgetown) Monitoring Site Location

Figure 3: New Amsterdam (Berbice) Monitoring Site Location

Figure 4: New Guyana School (Georgetown) Monitoring Site Location

At each location, the air quality analyzers were housed in a climate-controlled shelter, with ambient air drawn in for analysis through sample inlets. For PM_{10}, $PM_{2.5}$, CO, NO_2, SO_2, and H_2S measurements, ambient air was analyzed using continuous analyzers. Data from these continuous analyzers were reduced to 1-minute averages for storage and use in averaged concentration calculations. The VOC analyzer operated semi-continuously, with measurements recorded once every 6 minutes. The 6-minute data were then reduced to hourly averages.

An electrochemical total VOC sensor was used at the New Guyana School site, as the VOC analyzer was out of service during the New Guyana School site monitoring period (as described in Section 3). The sensor provided continuous output data. In conjunction with use of the total VOC sensor, eight passivated, evacuated Summa® canisters[4] were used to sequentially collect 24-hour integrated whole air samples for subsequent laboratory analysis via USEPA Method TO-15 (gas chromatography/mass spectrometry). These samples were analyzed for a suite of 75 organic compounds, including benzene, toluene, ethylbenzene, and xylenes (BTEX).

Carifesta site monitoring began on 15 August 2018 and concluded on 3 October 2018. Monitoring at the New Amsterdam location began on 15 October 2018 and concluded on 3 December 2018. A second Carifesta monitoring period was conducted from 11 December 2018 through 21 March 2019. New Guyana School site monitoring commenced on 12 April 2019 and concluded on 25 August 2019.

ERM considers 6 weeks (approximately 1,000 hours) of ambient air quality monitoring to be adequate to characterize baseline air quality in environments where there are relatively few major emission sources, the topography is simple, and climate conditions lack significant seasonality. The quantity of data exceeded this objective by more than 10 percent at each of the monitoring sites. Monitoring at New Guyana School was extended beyond 6 weeks to provide a dataset representative of the wet season.

[4] Summa canisters are specially treated to make them chemically non-reactive with specific air pollutants so that collected whole air samples do not degrade significantly during the interval between sampling and analysis.

2. AMBIENT AIR MONITORING RESULTS

2.1. PM_{10} Monitoring Results

Ambient concentrations of PM_{10} were measured continuously by a Teledyne API T640X, optical aerosol spectrometer. PM_{10} valid data recovery[5] was 91 percent during the first Carifesta monitoring period, 99 percent during the New Amsterdam monitoring, 97 percent during the second Carifesta monitoring period, and 97 percent during the monitoring at the New Guyana School site. Valid data recovery is a convenient metric on which to judge a monitoring program's technical performance. Valid data loss can result from power outage, instrument malfunction, or calibration/maintenance work that detracts from the time an instrument is measuring ambient air.

Since there are particulate matter guideline criteria for 24-hour average values, only those days for which sufficient hours of data were collected are appropriate for comparison to the 24-hour average particulate matter criterion. ERM used a threshold of at least 75 percent of possible hours (i.e., 18 hours) to be valid for the daily average to be considered valid. During the first Carifesta monitoring period, 45 days were designated as valid[6] for use in comparison with criteria. At New Amsterdam, 50 monitoring days were designated as valid for use in comparison with criteria. During the second Carifesta monitoring period, 93 days were designated as valid for use in comparison with criteria. At The New Guyana School, 132 days were designated as valid for use in comparison with criteria. The proportion of valid monitoring days provides context with which to assess whether the data are adequate for comparison with an ambient air quality criterion.

Table 5 presents a summary of the results of PM_{10} monitoring for all four monitoring periods. ERM's ambient air quality data recovery goal is 80 percent—consistent with international standard practice. All four monitoring periods exceeded this goal. Measured concentrations at the monitoring locations were compared to the 24-hour and annual WHO Guideline Values for PM_{10} (WHO 2021). 24-hour values were also compared with the USEPA PM_{10} guideline value.

Table 5: Summary of PM_{10} Monitoring Results

Site	Maximum 1-Hour Average ($\mu g/m^3$)	Maximum 24-Hour Average ($\mu g/m^3$)	Monitoring Period Average [a] ($\mu g/m^3$)	Data Recovery	Valid Monitoring Days
Carifesta #1 (dry season)	61.9	37.3	17.3	91%	45
Carifesta #2 (rainy season)	266.8	154.3	33.3	97%	93
Carifesta (combined)	266.8	154.3	28.3	95%	138
New Amsterdam	110.7	39.8	20.6	99%	50
New Guyana School	103.3	60.0	25.5	97%	132
Guideline(s)	—	45 (WHO) 150 (USEPA)	15 (WHO Annual)		

$\mu g/m^3$ = micrograms per cubic meter
[a] While the monitoring period data averages are compared to the annual criterion, if monitoring were performed for a full year, the resulting average data values would likely be lower than that for just the monitoring period. This is because air quality data tend to be log-normally distributed—having many very small values, with only intermittent high impacts.

[5] Valid data recovery percentage is the number of valid hourly measurements divided by total number of hours monitored, multiplied by 100.
[6] A valid monitoring day is one that obtained data for at least 18 of the 24 monitoring hours in the day.

At Carifesta during the first monitoring period, the maximum 24-hour average concentration was about 25 percent below the 24-hour WHO Guideline Value, while the average over the 45-day monitoring period was slightly above the WHO annual average criterion. The New Amsterdam monitoring yielded a maximum 24-hour average concentration that was about 20 percent below the 24-hour WHO Guideline Value, while the full monitoring period average of measured concentrations was slightly above the WHO annual average criterion. At Carifesta during the second monitoring period, the maximum 24-hour average concentration was approximately three times the corresponding WHO criterion, while the average over the 93-day monitoring period was about two times the annual average criterion. At New Guyana School, the maximum 24-hour average was about 33 percent above the criterion, while the full monitoring period average was approximately 70 percent over the annual WHO Guideline Value.

PM_{10} is generated primarily by physical operations. It is likely that the elevated concentrations monitored at all three sites were influenced by vehicle traffic (engine emissions, rubber tire dust, resuspended road dust) and open burning. Carifesta may have also received sea salt inputs due to its proximity to the coast. The New Amsterdam PM_{10} sources likely included impacts from agricultural emission sources (tilling, harvesting, and residue burning). At New Guyana School, the sources of PM_{10} ambient air impacts likely included agricultural, as well as vehicle emissions.

It should be noted that the comparison between the full monitoring period averages and the annual WHO Guideline Value should be considered indicative rather than directly comparable, as the guideline is an annual average, and the monitoring durations at all three sites were each less than 365 days. The nature of atmospheric dispersion is such that average values generally decrease as the averaging period increases.

The daily monitoring statistics for all three sites are presented in Attachment A and the hourly data record is presented in Attachment B.

2.2. $PM_{2.5}$ Monitoring Results

Ambient concentrations of $PM_{2.5}$ were measured continuously by a Teledyne API T640X, optical aerosol spectrometer. $PM_{2.5}$ valid data recovery was 91 percent during the first Carifesta monitoring period, 99 percent during the New Amsterdam monitoring, 97 percent during the second Carifesta monitoring period, and 97 percent during the monitoring at the New Guyana School site. During the first Carifesta period, 45 monitoring days were designated as valid for use in comparison with criteria. At New Amsterdam, 50 monitoring days were designated as valid for use in comparison with criteria. During the second Carifesta period, 93 days were designated as valid for use in comparison with criteria. At the New Guyana School, 132 days were designated as valid for comparison to criteria. Table 6 presents a summary of the results of $PM_{2.5}$ monitoring at the three monitoring site locations. Measured concentrations at all three monitoring locations were compared to the 24-hour and annual WHO Guideline Values for $PM_{2.5}$.

At Carifesta during the first monitoring period, the maximum 24-hour average measurement was slightly below the corresponding WHO standard, and the monitoring period average concentration was approximately 50 percent above the WHO annual Guideline Value. The New Amsterdam maximum 24-hour average concentration was slightly below the corresponding WHO Guideline Value, and the monitoring period average was approximately 50 percent above the annual criterion. At Carifesta during the second monitoring period, the maximum 24-hour average measurement was approximately three times the corresponding WHO standard, and the monitoring period average concentration was approximately two and a half times the WHO annual Guideline Value. The New Guyana School maximum 24-hour average concentration was slightly above the WHO Guideline Value, and the monitoring period average was about two times the WHO annual Guideline Value.

Table 6: Summary of $PM_{2.5}$ Monitoring Results

Location	Maximum 1-Hour Average ($\mu g/m^3$)	Maximum 24-Hour Average ($\mu g/m^3$)	Monitoring Period Average [a] ($\mu g/m^3$)	Data Recovery	Valid Monitoring Days
Carifesta #1 (dry season)	31.8	13.1	7.1	91%	45
Carifesta #2 (rain season)	92.7	53.1	12.7	97%	93
Carifesta (combined)	92.7	53.1	11.0	95%	138
New Amsterdam	38.3	13.5	6.8	99%	50
New Guyana School	45.8	18.2	9.3	97%	132
Guideline(s)	—	15 (WHO) 35 (USEPA)	5 (WHO Annual) 12 (USEPA Annual)		

$\mu g/m^3$ = micrograms per cubic meter
[a] While the monitoring period data averages are compared to the annual criterion, if monitoring were performed for a full year, the resulting average data values would likely be lower than that for just the monitoring period. This is because air quality data tend to be log-normally distributed—having many very small values, with only intermittent high impacts.

It should be noted that the comparison between the full monitoring period averages and the annual Guideline Values should be considered indicative rather than directly comparable, as the WHO Guideline Value is an annual average, and the duration of monitoring at each of the three locations was less than a full year. The nature of atmospheric dispersion is such that average values generally decrease as the averaging period increases. In addition, the USEPA guideline is stated as the average of 3 years of annual averages. The USEPA 24-hour guideline is meant to be compared to the 98th percentile maximum 24-hour average values.

In most cases, the primary source of $PM_{2.5}$ is atmospheric chemical reaction of precursor gases that forms fine particles. Common precursor gases are SO_2 and NO_2 from fuel combustion, as well as ammonia from livestock operations. Combustion emissions from vehicle engines and open burning are probably also $PM_{2.5}$ emission sources impacting the three monitoring sites.

The daily monitoring statistics for all three sites are presented in Attachment A and the hourly data record is presented in Attachment B.

2.3. Carbon Monoxide Monitoring Results

Ambient concentrations of CO were measured continuously by a Thermofisher Scientific Model 48i gas filter correlation analyzer. Monitored concentrations were adjusted, as needed, in post-processing based on the automated zero test of the analyzer. CO valid data recovery was 99 percent at the Carifesta location during the first monitoring period, 98 percent at the New Amsterdam location, 99 percent at Carifesta during the second monitoring period, and 95 percent at New Guyana School.

At the Carifesta site during the first monitoring period, 50 monitoring days were designated as valid for use in comparison with criteria; at the New Amsterdam site, 50 monitoring days were designated as valid for use in comparison with criteria; at Carifesta during the second monitoring period, 98 days were designated as valid for use in comparison with criteria; at the New Guyana School site, 131 monitoring days were designated as valid for comparison with criteria. Table 7 presents a summary of the results of CO monitoring at all three monitoring sites.

Measured concentrations at the Carifesta site during the first monitoring period were adjusted in post-processing based on the automated zero tests of the analyzer, as necessary, to account for instrument drift. Measured concentrations at all three monitoring locations were compared to the 1-hour and 8-hour average WHO and USEPA Guideline Values for CO. The maximum 1-hour and 8-hour average measured concentrations for all three sites are well below the Guideline Values.

The daily monitoring statistics for all the sites are presented in Attachment A and the hourly data record is presented in Attachment B.

Table 7: Summary of Carbon Monoxide Monitoring Results

Location	Maximum 1-Hour Average (ppm)	Maximum 8-Hour Average (ppm)	Monitoring Period Average (ppm)	Data Recovery	Valid Monitoring Days
Carifesta #1 (dry season)	1.36	1.01	0.43	99%	50
Carifesta #2 (rainy season)	1.45	1.15	0.51	99%	98
Carifesta (combined)	1.45	1.15	0.48	99%	148
New Amsterdam	1.05	0.66	0.35	98%	50
New Guyana School	1.20	0.86	0.49	95%	131
Guidelines	30.5 (WHO) 35 (USEPA)	8.7 (WHO) 8.7 (USEPA)	—		

ppm = parts per million

2.4. Nitrogen Dioxide Monitoring Results

Ambient concentrations of NO_2 were measured continuously by a Thermofisher Scientific Model 42i chemiluminescent analyzer. Measured concentrations at New Amsterdam were adjusted, as necessary, in post-processing based on the automated zero and span tests of the analyzer. NO_2 valid data recovery was 96 percent at the Carifesta location during the first monitoring period, 79 percent at the New Amsterdam location, 95 percent during the second monitoring period at Carifesta, and 93 percent at the New Guyana School site.

The New Amsterdam data recovery was slightly below the data recovery goal of 80 percent. While not ideal, 79 percent data recovery is generally adequate for characterizing ambient air quality. Many governmental agencies use 75 percent as their data recovery objective.

At Carifesta during the first monitoring period, 50 monitoring days were designated as valid for use in comparison to criteria; at the New Amsterdam site, 50 monitoring days were designated as valid for use in comparison to criteria; during the second monitoring period at Carifesta, 98 monitoring days were designated as valid for use in comparison to criteria; at the New Guyana School, 130 monitoring days were designated as valid for use in comparison to criteria. Table 8 presents a summary of the results of NO_2 monitoring at all three monitoring locations.

Table 8: Summary of Nitrogen Dioxide Monitoring Results

Location	Maximum 1-Hour Average (ppb)	Monitoring Period Average [a] (ppb)	Data Recovery	Valid Monitoring Days
Carifesta #1 (dry season)	15.0	3.1	96%	50
Carifesta #2 (rainy season)	12.5	-0.7 [b]	95%	98
Carifesta (combined)	15.0	0.6	95%	148
New Amsterdam	21.7	-1.4 [b]	79%	40
New Guyana School	15.8	1.3	93%	130
Guideline	106.4 (WHO) 100 (USEPA)	5.3 (WHO Annual) 53 (USEPA Annual)		

ppb = parts per billion
[a] While the monitoring period data averages are compared to the annual criterion, if monitoring were performed for a full year, the resulting average data values would likely be lower than that for just the monitoring period. This is because air quality data tend to be log-normally distributed—having many very small values, with only intermittent high impacts.
[b] Negative values result when ambient concentrations are very low and normal instrument drift results in a negative value. This is consistent with accepted reporting convention. If drift is excessive—usually due to instrument malfunction—negative values are invalidated.

Data recovery at the New Amsterdam location was adversely affected by the failure of the analyzer's internal pump and several instances of significant bleed-over of the automated challenge concentration. The bleed-over occurred when the air compressor that is used to supply zero gas was off or did not supply enough pressure to allow for the proper dilution of the calibration gas.

The maximum 1-hour average and the full monitoring period average of the measured concentrations were compared to the 1-hour and annual WHO and USEPA Guideline Values, respectively, for NO_2. At all three monitoring sites, the averages are well below the applicable Guideline Values.

It should be noted that the comparison between the full monitoring period averages and the annual Guideline Values should be considered indicative rather than directly comparable, as the Guideline Values are annual averages, and the duration of monitoring at each of the three sites was less than a full year. The nature of atmospheric dispersion is such that average values generally decrease as the averaging period increases. Therefore, it is expected that actual annual average values at the sites would be even further below the guideline value.

The daily monitoring statistics for both sites are presented in Attachment A and the hourly data record is presented in Attachment B.

2.5. Sulfur Dioxide Monitoring Results

Ambient concentrations of SO_2 were measured continuously by a Thermofisher Scientific Model 450i pulsed fluorescence analyzer. SO_2 valid data recovery was 96 percent at the Carifesta location during the first monitoring period, 95 percent at the New Amsterdam location, 95 percent during the second monitoring period at Carifesta, and 93 percent at the New Guyana School site. At the Carifesta site during the first monitoring period, 50 monitoring days were designated as valid for use in comparison to criteria; New Amsterdam had 50 days designated as valid for use in comparison to criteria; the second monitoring period at Carifesta had 98 days designated as valid for use in comparison to criteria; New Guyana School had 132 days designated as valid for use in comparison to criteria. Table 9 presents a summary of the results of SO_2 monitoring at all three locations.

Table 9: Summary of Sulfur Dioxide Monitoring Results

Location	Maximum Daily 1-hour Average (ppb)	Maximum 24-Hour Average (ppb)	Monitoring Period Average (ppb)	Data Recovery	Valid Monitoring Days
Carifesta #1 (dry season)	7.2	0.3	-1.0 [a]	96%	50
Carifesta #2 (rainy season)	2.9	0.3	-0.1 [a]	95%	98
Carifesta (combined)	7.2	0.3	-0.4 [a]	95%	148
New Amsterdam	-0.1 [a]	-1.0 [a]	-1.3 [a]	95%	50
New Guyana School	11.7	3.3	0.9	93%	132
Guideline	75 (USEPA)	15 (WHO)	—		

ppb = parts per billion
[a] Negative values result when ambient concentrations are very low and normal instrument drift results in a negative value. This is consistent with accepted reporting convention. If drift is excessive—usually due to instrument malfunction—negative values are invalidated.

The maximum 1-hour average and the maximum 24-hour average of the measured SO_2 concentrations at all three monitoring sites were compared to the 1-hour USEPA standard and the 24-hour WHO Guideline Value, respectively. At all three monitoring sites, the averages are well below the SO_2 criteria.

The daily monitoring statistics for both sites are presented in Attachment A and the hourly data record is presented in Attachment B.

2.6. Hydrogen Sulfide Monitoring Results

Ambient concentrations of H_2S were measured continuously by a Thermofisher Scientific Model 450i pulsed fluorescence analyzer. H_2S valid data recovery was 96 percent at the Carifesta location during the first monitoring period, 95 percent at the New Amsterdam location, 95 percent during the second monitoring period at Carifesta, and 93 percent at the New Guyana School site.

At Carifesta during the first monitoring period, 50 monitoring days were designated as valid for use in comparison to criteria; at the New Amsterdam site, 50 days were designated as valid for use in comparison to criteria; during the second monitoring period at Carifesta, 98 days were designated as valid for use in comparison to criteria; at New Guyana School 132 days were designated as valid for use in comparison to criteria. Table 10 presents a summary of the results of H_2S monitoring at all three locations.

The maximum 24-hour average of the measured concentrations at all three monitoring sites was compared to the 24-hour WHO Guideline Value for H_2S. The averages at all three sites are well below the WHO Guideline Value.

The daily monitoring statistics for all three sites are presented in Attachment A and the hourly data record is presented in Attachment B.

Table 10: Summary of Hydrogen Sulfide Monitoring Results

Location	Maximum 30-Minute Average (ppb)	Maximum 24-Hour Average (ppb)	Monitoring Period Average (ppb)	Data Recovery	Valid Monitoring Days
Carifesta #1 (dry season)	14.2	1.9	0.4	96%	50
Carifesta #2 (rainy season)	32.4	1.3	0.1	95%	98
Carifesta (combined)	32.4	1.9	0.2	95%	148
New Amsterdam	5.8	0.4	-0.1 [a]	95%	50
New Guyana School	110.6	16.0	2.8	93%	132
Guideline		107.6 (WHO 24-hour)	—		

ppb = parts per billion
[a] Negative values result when ambient concentrations are very low and normal instrument drift results in a negative value. This is consistent with accepted reporting convention. If drift is excessive—usually due to instrument malfunction—negative values are invalidated.

2.7. Benzene Monitoring Results

Ambient concentrations of benzene were measured semi-continuously by a Mocon Baseline Series 9100 gas chromatograph at the Carifesta site (Carifesta #1 only), at the New Amsterdam site, and for a portion of the monitoring period at the New Guyana School site. The gas chromatograph failed subsequent to the New Amsterdam deployment and was sent back to the manufacturer to be serviced before being reinstalled at New Guyana School on 27 June. In the place of the Mocon, eight Summa air samples were collected at New Guyana School and analyzed for benzene in addition to other VOCs.

Benzene valid data recovery was 95 percent at the Carifesta location, 99 percent at the New Amsterdam location, and 74 percent at New Guyana School.

At Carifesta, 47 monitoring days were designated as valid for use in comparison to criteria; at New Amsterdam, 50 monitoring days were designated as valid for use in comparison to criteria; and at New Guyana School, 21 monitoring days were designated as valid for use in comparison to criteria. Analyses of all eight New Guyana School Summa samplers were valid. Table 11 presents a summary of the results of benzene monitoring at each location.

Table 11: Summary of Benzene Monitoring Results

Location	Maximum 1-Hour Average (ppb)	Maximum 24-Hour Average (ppb)	Monitoring Period Average (ppb)	Data Recovery	Valid Monitoring Days
Carifesta #1 (dry season)	1,272.6	131.9	18.4	95%	47
Carifesta #2 (rainy season)	NA	NA	NA	NA	NA
Carifesta (combined)	NA	NA	NA	NA	NA
New Amsterdam	7.9	0.4	0.0	99%	50
New Guyana School [a]	NA	0.7	NA	NA	8
New Guyana School [b]	16.1	0.8	0.0	74%	21
Guideline	—	9.4 (USEPA)	—		

NA = not applicable; ppb = parts per billion
[a] Data from integrated 24-hour Summa samples
[b] Data from Mocon installed on 27 June and operated until 22 August

The maximum 24-hour average of the measured concentrations at each of the three monitoring locations was compared to the 24-hour USEPA Reference Concentration. At Carifesta, the maximum 24-hour average was significantly higher than the Reference Concentration. The maximum 24-hour average value includes a single 6-minute sample that registered well above the calibration range of the analyzer. While this anomalous measurement is considered to be an outlier, it was not invalidated since all quality control parameters were within tolerance.

Even if the outlier value is excluded, the maximum 24-hour average would still have exceeded the Reference Concentration by more than 50 percent at the Carifesta site. Motor vehicle emissions may have been responsible for the measured values, since there are no obvious nearby stationary benzene emission sources upwind of the Carifesta site.

At the New Amsterdam and the New Guyana School monitoring sites, the maximum 24-hour average benzene measurements were significantly lower than the Reference Concentration.

The daily monitoring statistics for the Carifesta and New Amsterdam sites are presented in Attachment A and the hourly data record is presented in Attachment B. The New Guyana School measurements were limited to eight values from Summa samples. The benzene results for all eight samples are discussed in Section 2.11.

2.8. Toluene Monitoring Results—Carifesta and New Amsterdam

Ambient concentrations of toluene were measured semi-continuously by a Mocon Baseline Series 9100 gas chromatograph at the Carifesta site (Carifesta #1 only), the New Amsterdam site, and for a portion of the monitoring period at the New Guyana School site. The eight Summa air samples collected at New Guyana School were analyzed for toluene in addition to other VOCs. Toluene valid data recovery was 94 percent at the Carifesta location, 99 percent at the New Amsterdam location, and 74 percent at the New Guyana School location. Analyses of all eight New Guyana School Summa samples were valid.

At Carifesta, 47 monitoring days were designated as valid for comparison to criteria; at New Amsterdam, 50 monitoring days were designated as valid for comparison to criteria; at New Guyana School, 21 monitoring days were designated as valid for comparison to criteria. Table 12 presents a summary of the results of toluene monitoring at each location.

Table 12: Summary of Toluene Monitoring Results

Location	Maximum 1-Hour Average (ppb)	Maximum 24-Hour Average (ppb)	Maximum Weekly Average (ppb)	Data Recovery	Valid Monitoring Days
Carifesta #1 (dry season)	1,134.6	169.5	20.7	94%	47
Carifesta #2 (rainy season)	NA	NA	NA	NA	NA
Carifesta (combined)	NA	NA	NA	NA	NA
New Amsterdam	6.7	5.4	5.0	99%	50
New Guyana School [a]	NA	6.0	NA	100%	8
New Guyana School [b]	2,396.7	99.9	0.0	74%	21
Guideline	—	—	69 (WHO)		

NA = not applicable; ppb = parts per billion
[a] Data from integrated 24-hour Summa samples
[b] Data from Mocon installed on 27 June and operated until 22 August

The maximum weekly averages at the Carifesta, New Amsterdam, and New Guyana School sites were compared to the WHO 1-week Guideline Value. At all three sites, the weekly averages are below the WHO Guideline Value.

The daily monitoring statistics for all sites are presented in Attachment A and the hourly data record is presented in Attachment B. The toluene results for all eight Summa samples are discussed in Section 2.11.

2.9. Ethylbenzene Monitoring Statistics—Carifesta and New Amsterdam

Ambient concentrations of ethylbenzene were measured semi-continuously by a Mocon Baseline Series 9100 gas chromatograph at the Carifesta site (Carifesta #1 only), at the New Amsterdam site, and for a portion of the monitoring period at the New Guyana School site. The eight Summa air samples collected at New Guyana School were analyzed for ethylbenzene in addition to other VOCs. Ethylbenzene valid data recovery was 94 percent at the Carifesta location, 99 percent at the New Amsterdam location, and 74 percent at New Guyana School. Analyses of all eight Summa samples collected at the New Guyana School site were valid.

At Carifesta, 47 monitoring days were designated as valid for comparison to criteria; at New Amsterdam, 50 monitoring days were designated as valid for comparison to criteria; at New Guyana School, 21 monitoring days were designated as valid for comparison to criteria. Table 13 presents a summary of the results of ethylbenzene monitoring at the three monitoring sites.

The full monitoring period average concentrations at all three sites were compared to the USEPA annual average Reference Concentration for ethylbenzene. The monitoring period averages are well below the USEPA Reference Concentration at all three sites.

It should be noted that the comparison between the full monitoring period average and the annual USEPA Reference Concentration should be considered indicative rather than directly comparable, as the USEPA Reference Concentration is an annual average and the duration of monitoring at each site was considerably less than 365 days. The nature of atmospheric dispersion is such that average values generally decrease as the averaging period increases. Therefore, it is expected that actual annual average values at all three sites would be even further below the USEPA annual Reference Concentration.

Table 13: Summary of Ethylbenzene Monitoring Results

Location	Maximum 1-Hour Average (ppb)	Maximum 24-Hour Average (ppb)	Monitoring Period Average (ppb)	Data Recovery	Valid Monitoring Days
Carifesta #1 (dry season)	31.6	3.3	0.08	94%	47
Carifesta #2 (rainy season)	NA	NA	NA	NA	NA
Carifesta (combined)	NA	NA	NA	NA	NA
New Amsterdam	0.6	0.1	0.0	99%	50
New Guyana School [a]	NA	0.2	ND	100%	8
New Guyana School [b]	18.4	0.0	0.0	74%	21
Guideline	—	—	0.23 [c] (USEPA Annual)		

NA = not applicable; ND = below minimum laboratory reporting level of 0.14 ppb by volume; ppb = parts per billion
[a] Data from integrated 24-hour Summa samples
[b] Data from Mocon installed on 27 June and operated until 22 August
[c] While the monitoring period data averages are compared to the annual criterion, if monitoring were performed for a full year, the resulting average data values would likely be lower than that for just the monitoring period. This is because air quality data tend to be log-normally distributed—having many very small values, with only intermittent high impacts.

The Carifesta and New Amsterdam daily monitoring statistics for all sites are presented in Attachment A and the hourly data record is presented in Attachment B. The New Guyana School ethylbenzene Summa results for all eight samples are discussed in Section 2.11.

2.10. Xylenes Monitoring Statistics—Carifesta and New Amsterdam

Ambient concentrations of xylenes were measured semi-continuously by a Mocon Baseline Series 9100 gas chromatograph at the Carifesta site (Carifesta #1 only), at the New Amsterdam site, and for a portion of the monitoring period at the New Guyana School site. The eight Summa air samples collected at New Guyana School were analyzed for xylenes in addition to other VOCs. Xylenes valid data recovery was 94 percent at the Carifesta location, 99 percent at the New Amsterdam location, and 74 percent at the New Guyana School location. Xylenes analyses of all eight New Guyana School Summa samples were valid. At Carifesta, 47 monitoring days were designated as valid for comparison to criteria; at New Amsterdam, 50 monitoring days were designated as valid for comparison to criteria; at New Guyana School, 21 days were designated as valid for comparison to criteria. Table 14 presents a summary of the results of xylenes monitoring at all three locations.

Table 14: Summary of Xylenes Monitoring Results

Location	Maximum 1-Hour Average (ppb)	Maximum 24-Hour Average (ppb)	Monitoring Period Average (ppb)	Data Recovery	Valid Monitoring Days
Carifesta #1 (dry season)	137.1	12.3	0.4	94%	47
Carifesta #2 (rainy season)	NA	NA	NA	NA	NA
Carifesta (combined)	NA	NA	NA	NA	NA
New Amsterdam	14.4	0.9	0.1	99%	50
New Guyana School [a]	NA	0.6	NA	100%	8
New Guyana School [b]	0.0	0.0	0.0	74%	21
Guideline	—	100 (USEPA)	—		

NA = not applicable; ppb = parts per billion
[a] Data from integrated 24-hour Summa samples
[b] Data from Mocon installed on 27 June and operated until 22 August

The maximum 24-hour averages of the measured concentrations at all three monitoring locations were compared to the 24-hour USEPA Reference Concentration. At Carifesta, New Amsterdam, and New Guyana School, the 24-hour averages are well below the USEPA Reference Concentration.

The Carifesta and New Amsterdam daily monitoring statistics for both sites are presented in Attachment A and the hourly data record is presented in Attachment B. The New Guyana School xylenes Summa results for all eight samples are discussed in Section 2.11.

2.11. Total Volatile Organic Compound Sensor Monitoring and Summa Canister Analysis Statistics—New Guyana School

Quality control checks revealed that the Mocon Baseline Series 9100 gas chromatograph failed at the beginning of the monitoring system's second Carifesta deployment. Upon installation at the New Guyana School site, the gas chromatograph was replaced by an electrochemical total VOC sensor until the Mocon could be serviced by the manufacturer and returned for operation. While the VOC sensor was not capable of discerning between VOC species, total VOC constitutes an upper limit on the concentration of a single or combination of VOC components. The sensor provided continuous data output until 27 June 2019 when the Mocon was successfully reinstalled and verified.

In conjunction with the use of the total VOC sensor, eight passivated, evacuated Summa canisters were used to sequentially collect 24-hour integrated whole air samples for subsequent laboratory analysis via USEPA Method TO-15 (gas chromatography/mass spectrometry). These samples were analyzed for a suite of 75 organic compounds, including the BTEX compounds. The Summa results, presented in Table 15, were used to directly compare ambient air quality to the BTEX compound criteria.

Data recovery from the total VOC sensor at the New Guyana School site was 90 percent through 27 June 2019. Table 16 presents a summary of the results of the total VOC concentrations measured at New Guyana School.

Table 15: Summary of New Guyana School Summa BTEX Monitoring Results

Sample Date	24-Hour Average Concentration [ppb(v)]			
	Benzene	Toluene	Ethylbenzene	Xylenes
16 April 2019	0.69	6.00	ND	0.42
17 April 2019	ND	3.80	ND	ND
26 April 2019	ND	0.81	ND	ND
27 April 2019	0.24	0.68	ND	ND
16 May 2019	0.52	2.1	0.21	0.62
27 May 2019	0.24	4.8	0.19	0.64
29 May 2019	0.43	3.0	0.17	0.47
3 June 2019	0.36	0.26	ND	ND
Maximum	**0.69**	**6.00**	**0.21**	**0.64**
WHO 1-Week Average Criterion	—	59	—	—
USEPA 24-Hour Average Criterion	9.4	—	—	100
USEPA Annual Average Criterion	—	—	0.23	—

ND = below laboratory minimum reporting level; ppb(v) = parts per billion by volume
Note: Summa results are only available as 24-hour average values. Caution must be exercised in comparing these data with criteria that are stated in terms of different averaging times.

There are no generally accepted ambient air quality criteria for total VOCs. Therefore, the maximum total VOC measurements were compared to the WHO/USEPA criteria for each of the BTEX compounds. Since total VOC represents the maximum potential concentration of any single VOC compound, this assessment is conservative. The daily total VOC monitoring statistics are presented in Attachment A and the hourly data record is presented in Attachment B.

Table 16: Summary of New Guyana School Total VOC Sensor Monitoring Results

		Maximum 1-Hour Average (ppb)	Maximum 24-Hour Average (ppb)	Maximum Weekly Average (ppb)	Monitoring Period Average (ppb)
Monitoring Results		39.0	14.8	7.90	4.93
Compound	**Source**	**Criteria**			
Benzene	USEPA	—	9.4	—	—
Toluene	WHO	—	—	59	
Ethylbenzene	USEPA	—	—	—	0.23 (annual average [a])
Xylenes	USEPA	—	100	—	—

ppb = parts per billion
[a] While the monitoring period data average is compared to the annual criterion, if monitoring were performed for a full year, the resulting average data values would likely be lower than that for just the monitoring period. This is because air quality data tend to be log-normally distributed—having many very small values, with only intermittent high impacts.

Table 17 compares the Summa canister total VOC results with the corresponding VOC sensor measurements. The sensor concentrations are uniformly lower than the Summa laboratory values. While most sensor values agree with the Summa concentrations within a factor of ten, in one case the sensor result is more than two orders of magnitude less than the Summa measurement over the same time period.

Table 17: New Guyana School VOC Sensor vs VOC Summa Canister Results

Sample Date	24-Hour Average Concentration [ppb(v)]	
	Summa Canisters	VOC Sensor
16 April 2019	148.3	1.3
17 April 2019	80.5	1.7
26 April 2019	103.1	4.0
27 April 2019	88.0	4.4
16 May 2019	21.4	4.9
27 May 2019	45.3	4.1
29 May 2019	35.2	4.8
3 June 2019	93.0	10.3
Maximum	**148.3**	**10.3**

Criteria				
	Benzene	**Toluene**	**Ethylbenzene**	**Xylene**
WHO 1-Week Average Criterion	—	59	—	—
USEPA 24-Hour Average Criterion	9.4	—	—	100
USEPA Annual Average Criterion	—	—	0.23	—

ppb(v) = parts per billion by volume

These results are consistent with other studies comparing reference methods with low-cost sensor measurements. Based on comparison with the Summa results, the sensor data should only be used on a qualitative basis (i.e., to assess variability concentrations) and the Mocon gas chromatograph and Summa canister results should be relied upon for quantifying concentrations.

3. NEW GUYANA SCHOOL: DRY VS. WET SEASON COMPARISON

EEPGL extended monitoring at New Guyana School past the initially-planned 6-week monitoring period, to explore possible inter-seasonal differences. Guyana's climate is such that ambient temperatures are fairly constant year-round. The only significant seasonal variation is in the amount of rainfall. This section presents the results of our analysis of ambient air quality variation as a function of "wet" versus "dry" season.

The expanded monitoring period ran from 12 April until 25 August 2019, which encompassed the entire main wet season that occurs from May to mid-July. Since the wet season occurred in the middle of the monitoring period, the statistics are broken down into three sub-periods: the first being 19 days before the start of the wet season ("Dry #1"), the second being the 72 days during the wet season ("Wet"), and the third being the 41 days after the wet season, until the end of the monitoring period ("Dry #2").

In some cases, air contaminant concentrations have been found to have a seasonal dependence due to either seasonal variation in emission patterns or meteorological factors. It is common to see a negative correlation between ground-level contaminant concentrations and rain intensity due to scavenging of pollutants by the rain. The actual mechanism by which precipitation scavenges a pollutant depends on the target pollutant. Rainout, washout, dissolution, and heterogeneous chemical reaction are all potential mechanisms. This section provides an initial assessment as to whether Georgetown air quality, of which the New Guyana School is representative, showed a seasonal variation during the monitoring period. The relatively short monitoring period does not support definitive conclusions—just observational descriptions.

Tables 18 through 23 present summaries of the New Guyana School monitoring results during the three sub-periods. Measured concentrations during all three sub-periods were compared to their respective WHO Guideline Values. Figures 5 through 10 are time series graphs of each parameter, differentiated by each of the three sub-periods. The vertical green line on each graph represents the beginning of the wet season (1 May) and the vertical red line represents the end of the wet season (15 July).

The horizontal black line represents the WHO Guideline for each respective parameter. Visual inspection does not illustrate an obvious season-dependent concentration difference for any of the monitored air contaminants. The lack of any clear relationships between rainfall and concentrations may be due to the relatively low measured concentrations of most parameters.

3.1. PM_{10} Dry Season vs. Wet Season Analysis

At New Guyana School, the wet season sub-period average for PM_{10} was 26.4 micrograms per cubic meter (µg/m^3)—in between Dry #1's and Dry #2's 33.2 and 20.5 µg/m^3 period averages, respectively. Reviewing the time series graph (Figure 5) does not indicate a strong seasonal difference.

Table 18: Summary of New Guyana School Wet vs. Dry Season PM_{10} Statistics

PM_{10} Concentration (µg/m³)					
New Guyana School Dry Season #1 (12/04/2019–30/04/2019)					
New Guyana School Wet Season (01/05/19–15/07/19)					
New Guyana School Dry Season #2 (16/07/19–25/08/19)					
Season	Maximum 1-Hour Average	Maximum 24-Hour Average	Period Average	Data Recovery	Valid Data Days
Dry #1	84.9	47.7	33.2	100%	19
Wet	82.2	60.0	26.4	95%	72
Dry #2	103.3	35.8	20.5	99%	41
Air Quality Guideline Values		45 (WHO) 150 (USEPA)	15 (WHO Annual)		

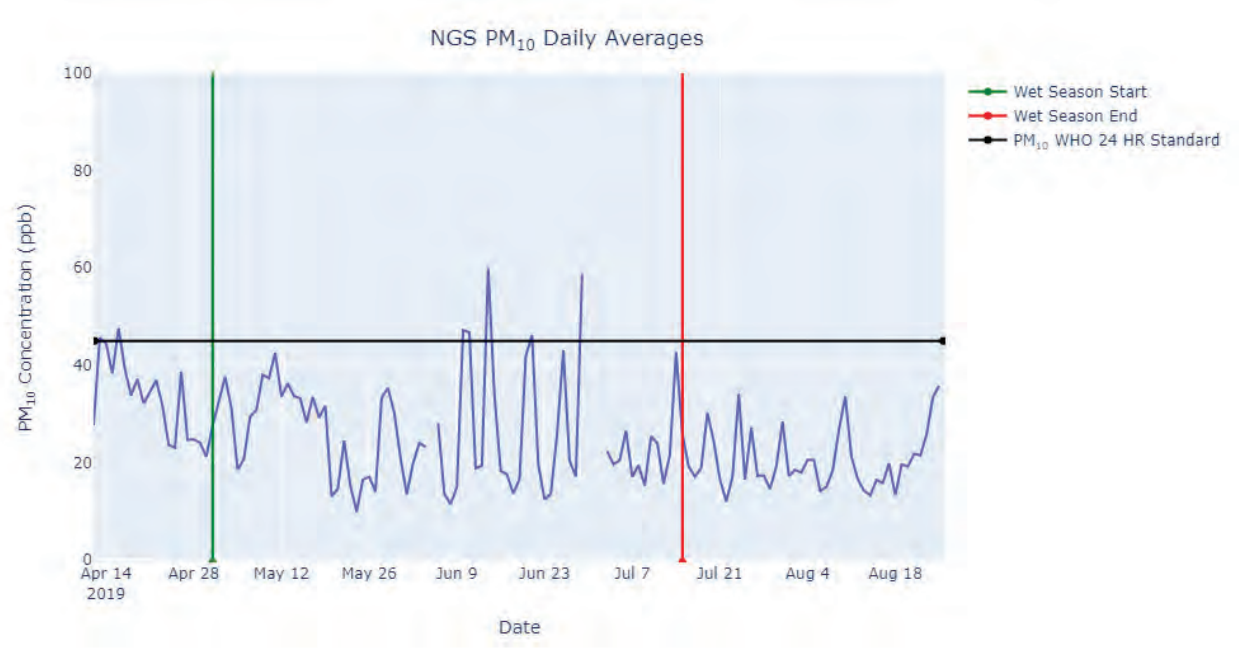

Figure 5: New Guyana School PM_{10} Time Series

3.2. $PM_{2.5}$ Dry Season vs. Wet Season Analysis

At New Guyana School, the wet season sub-period average for $PM_{2.5}$ was 9.3 µg/m³—in between Dry #1's and Dry #2's 12.3 and 7.9 µg/m³ period averages, respectively. Reviewing the time series graph (Figure 6) does not indicate a strong seasonal difference.

Table 19: Summary of New Guyana School Wet vs. Dry Season $PM_{2.5}$ Statistics

$PM_{2.5}$ Concentration ($\mu g/m^3$)					
New Guyana School Dry Season #1 (12/04/2019–30/04/2019)					
New Guyana School Wet Season (01/05/19–15/07/19)					
New Guyana School Dry Season #2 (16/07/19–25/08/19)					
Season	Maximum 1-Hour Average	Maximum 24-Hour Average	Period Average	Data Recovery	Valid Data Days
Dry #1	45.8	16.4	12.3	100%	19
Wet	32.1	18.2	9.3	95%	72
Dry #2	40.5	14.0	7.9	99%	41
Air Quality Guideline Values		15 (WHO) 35 (USEPA)	5 (WHO Annual) 12 (USEPA Annual)		

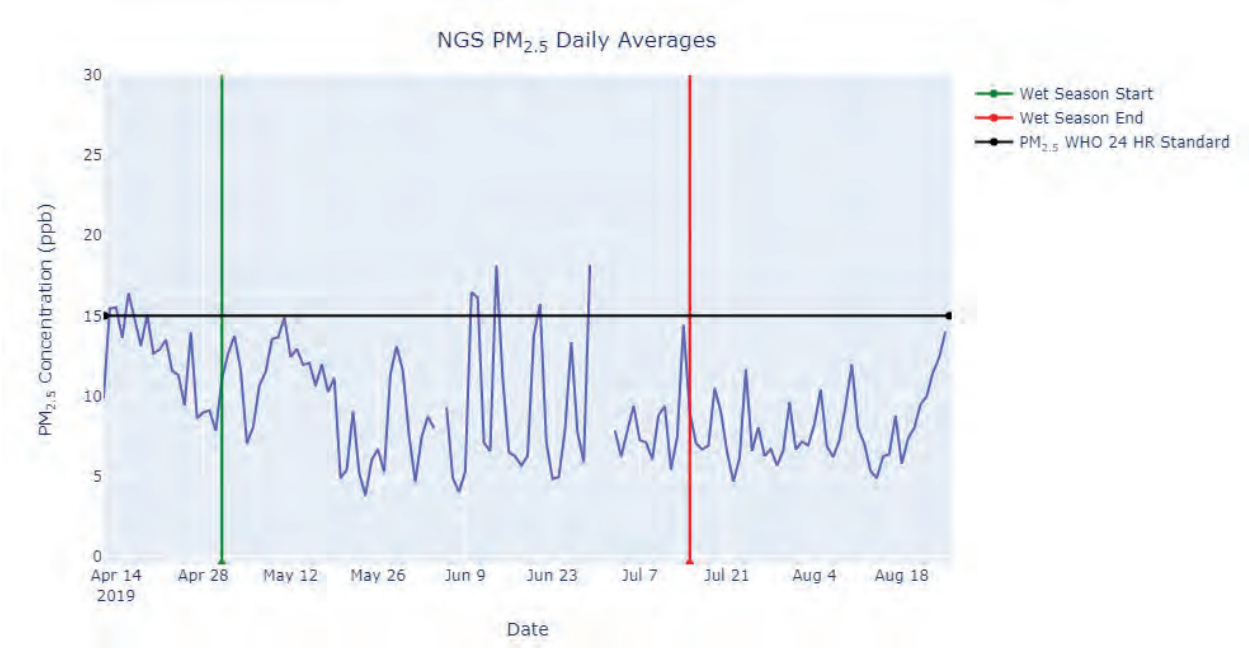

Figure 6: New Guyana School $PM_{2.5}$ Time Series

3.3. CO Dry Season vs. Wet Season Analysis

At New Guyana School, the wet season sub-period average for CO was 0.52 parts per million (ppm)—in between Dry #1's and Dry #2's 0.11 and 0.63 ppm period averages, respectively. Reviewing the time series graph (Figure 7) does not indicate a strong seasonal difference.

Table 20: Summary of New Guyana School Wet vs. Dry Season CO Statistics

CO Concentration (ppm)					
New Guyana School Dry Season #1 (12/04/2019–30/04/2019)					
New Guyana School Wet Season (01/05/19–15/07/19)					
New Guyana School Dry Season #2 (16/07/19–25/08/19)					
Season	Maximum 1-Hour Average	Maximum 8-Hour Average	Period Average	Data Recovery	Valid Data Days
Dry #1	0.76	0.34	0.11	99%	19
Wet	1.20	0.86	0.52	94%	72
Dry #2	1.09	0.86	0.63	96%	40
Air Quality Guideline Values	30.5 (WHO) 35 (USEPA)	8.7 (WHO) 8.7 (USEPA)			

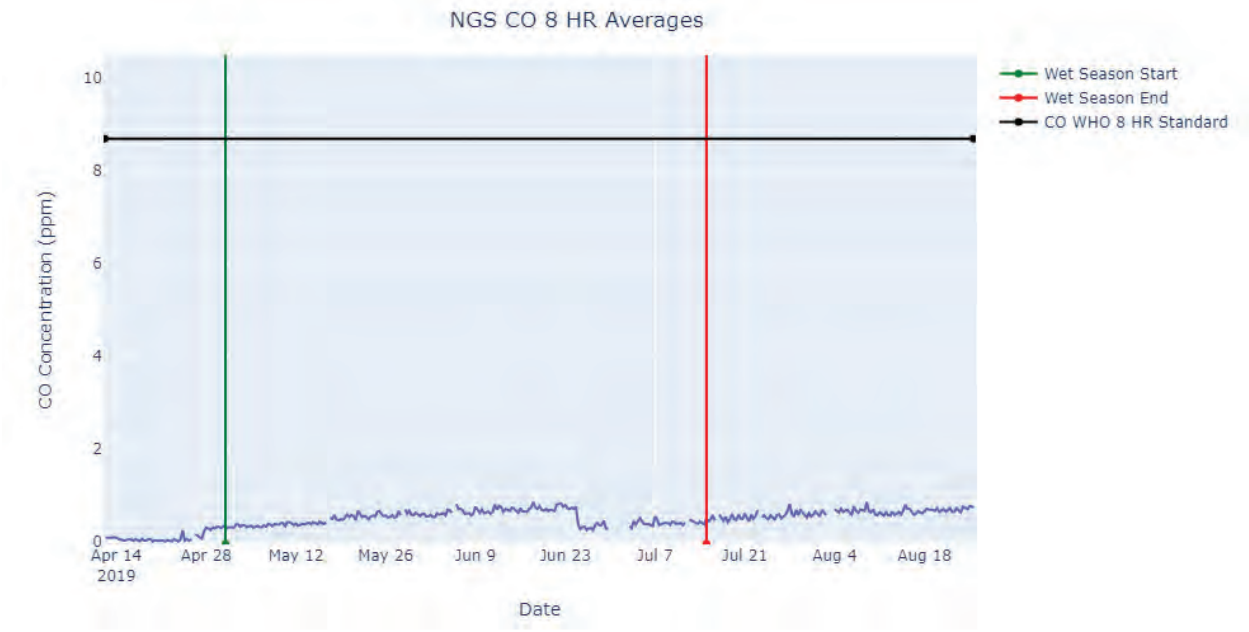

Figure 7: New Guyana School CO Time Series

3.4. NO_2 Dry Season vs. Wet Season Analysis

At New Guyana School, the wet season sub-period average for NO_2 was 1.1 parts per billion (ppb)—slightly below Dry #1's and Dry #2's 1.2 and 1.6 ppb period averages, respectively. Reviewing the time series graph (Figure 8) does not indicate a strong seasonal difference.

Table 21: Summary of New Guyana School Wet vs. Dry Season NO_2 Statistics

NO_2 Concentration (ppb)				
New Guyana School Dry Season #1 (12/04/2019–30/04/2019)				
New Guyana School Wet Season (01/05/19–15/07/19)				
New Guyana School Dry Season #2 (16/07/19–25/08/19)				
Season	Maximum 1-Hour Average	Period Average	Data Recovery	Valid Data Days
Dry #1	7.7	1.2	95%	19
Wet	12.2	1.1	92%	71
Dry #2	15.8	1.6	93%	40
Air Quality Guideline Values	106.4 (WHO) 100 (USEPA)	5.3 (WHO Annual) 53 (USEPA Annual)		

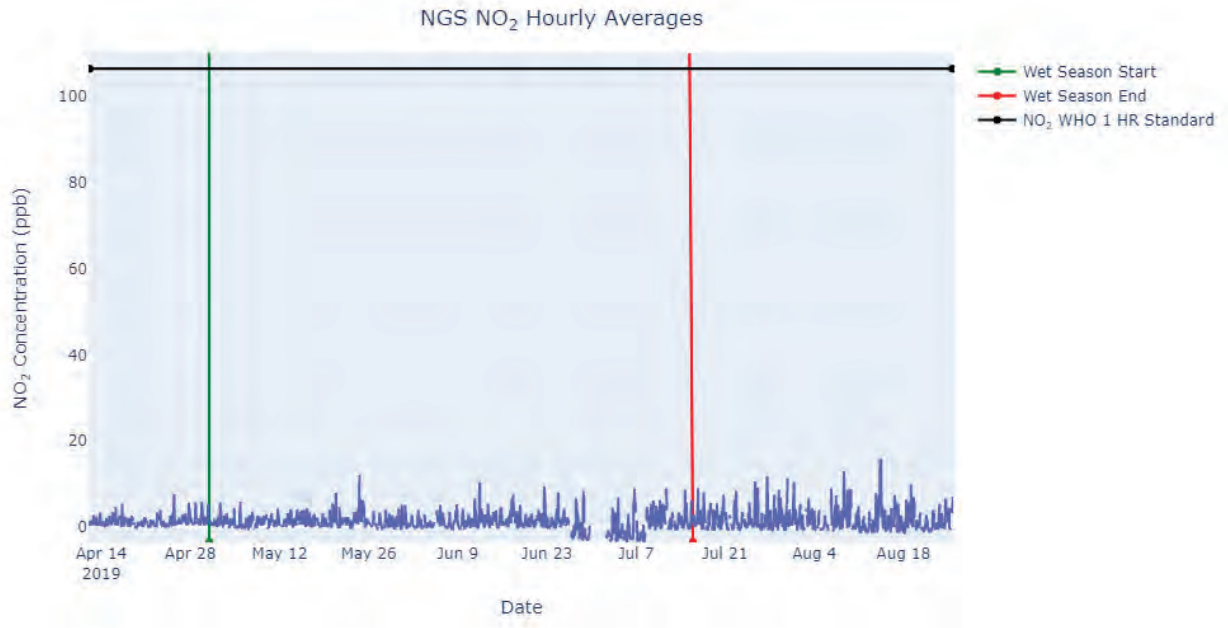

Figure 8: New Guyana School NO_2 Time Series

3.5. SO_2 Dry Season vs. Wet Season Analysis

At New Guyana School, the wet season sub-period average for SO_2 was 0.9 ppb—the same as for Dry #1 and slightly below Dry #2's 1.1 ppb period average. Reviewing the time series graph (Figure 9) does not indicate a strong seasonal difference.

Table 22: Summary of New Guyana School Wet vs. Dry Season SO_2 Statistics

SO_2 Concentration (ppb)					
New Guyana School Dry Season #1 (12/04/2019–30/04/2019)					
New Guyana School Wet Season (01/05/19–15/07/19)					
New Guyana School Dry Season #2 (16/07/19–25/08/19)					
Season	Maximum Daily 1-hour Average	Maximum 24-Hour Average	Period Average	Data Recovery	Valid Data Days
Dry #1	3.6	1.1	0.9	95%	19
Wet	11.7	1.7	0.9	92%	72
Dry #2	7.9	3.3	1.1	94%	41
Air Quality Guideline Values	75 (USEPA)	15 (WHO)			

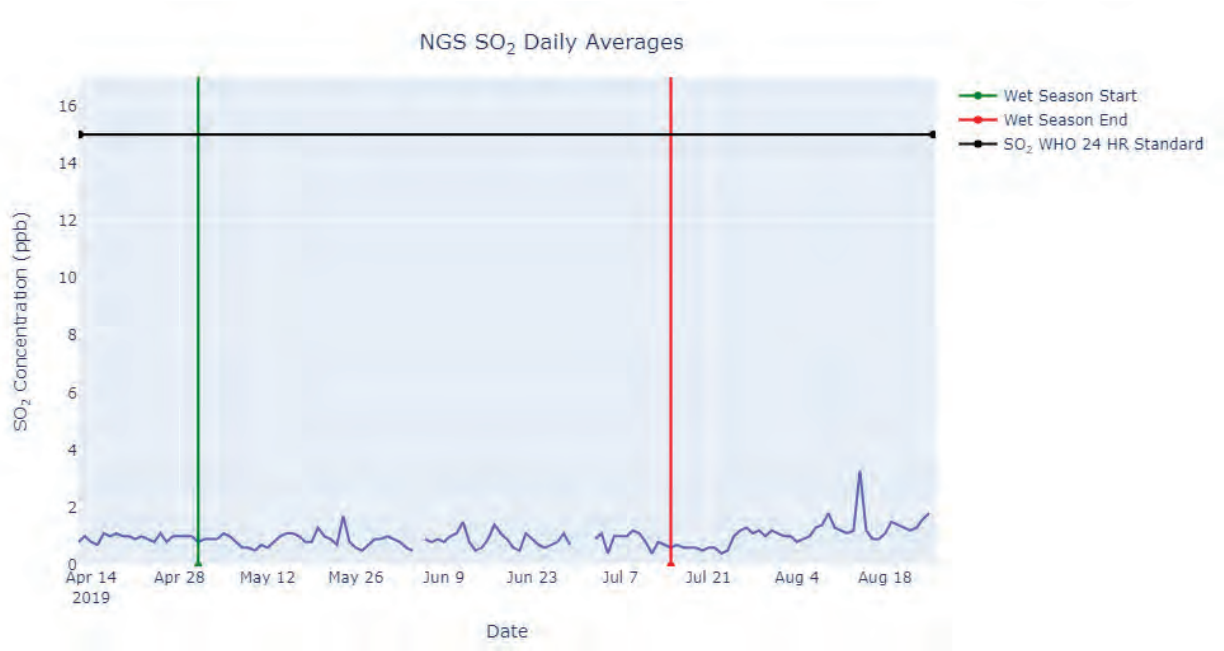

Figure 9: New Guyana School SO_2 Time Series

3.6. H_2S Dry Season vs. Wet Season Analysis

At New Guyana School, the wet season sub-period average for H_2S was 3.0 ppb—in between Dry #1's and Dry #2's 6.0 and 0.8 ppb period averages, respectively. Reviewing the time series graph (Figure 10) does not indicate a strong seasonal difference.

Table 23: Summary of New Guyana School Wet vs. Dry Season H_2S Statistics

H_2S Concentration (ppb)					
New Guyana School Dry Season #1 (12/04/2019–30/04/2019)					
New Guyana School Wet Season (01/05/19–15/07/19)					
New Guyana School Dry Season #2 (16/07/19–25/08/19)					
Season	Maximum 1-Hour Average	Maximum 24-Hour Average	Period Average	Data Recovery	Valid Data Days
Dry #1	71.8	14.5	6.0	95%	19
Wet	69.6	16.0	3.0	92%	72
Dry #2	75.9	5.7	0.8	94%	41
Air Quality Guideline Values	—	107.6 (WHO 24-hour)			

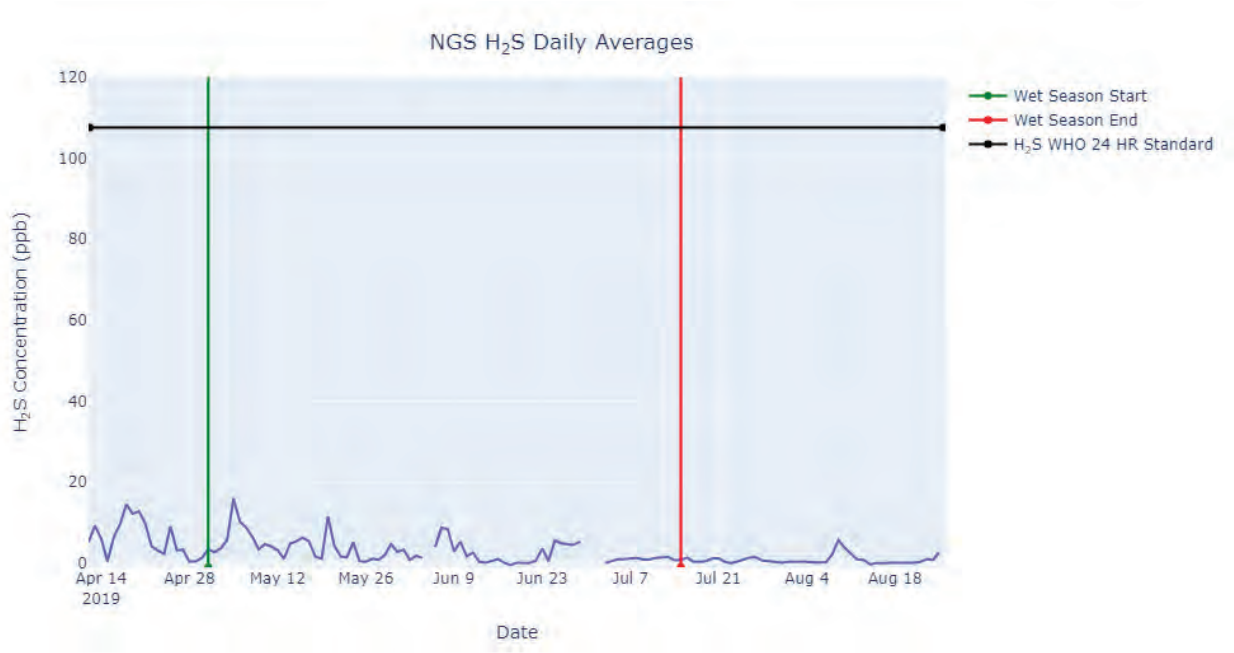

Figure 10: New Guyana School H_2S Time Series

4. WIND SPEED AND DIRECTION

Ambient wind speed and direction were continuously monitored by an RM Young Model 05305-5 mechanical anemometer, which was tripod-mounted on top of the monitoring shelter. The monitoring program statistics for wind speed are presented in Table 24; statistics for standard deviation of wind direction ("sigma theta"—an indicator of turbulence) are presented in Table 25. Data recovery goals were met for all meteorological parameters.

Table 24: Wind Speed Summary Statistics

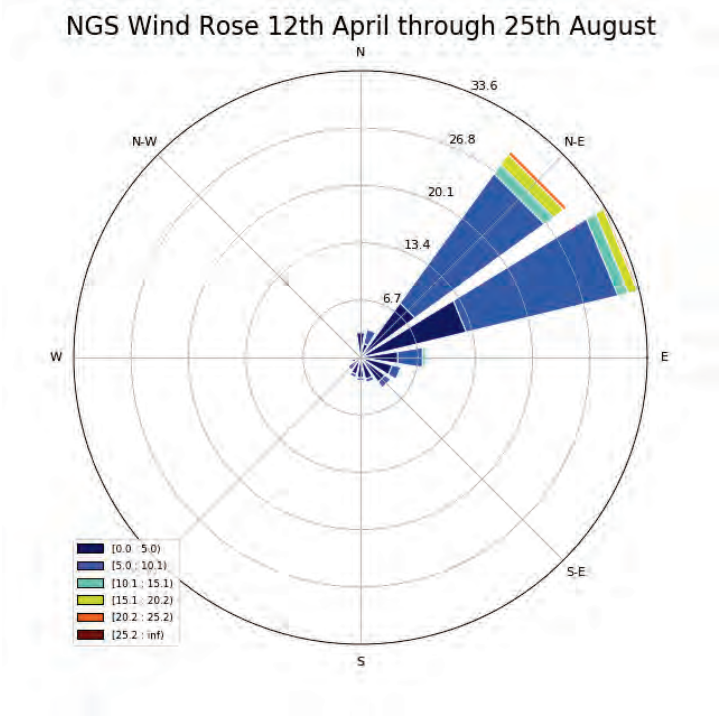
New Guyana School: 12/04/2019–25/08/2019			
Wind Speed (miles per hour)			
Minimum	Maximum	Average	Recovery
0.0	25.2	5.5	99%

Table 25: Sigma Theta Summary Statistics

New Guyana School: 12/04/2019–25/08/2019			
Sigma Theta (deg.)			
Minimum	Maximum	Average	Recovery
0.0	51.23	18.14	99%

Sigma theta measurements, with an average of 18.14 degrees, are representative of relatively steady wind direction measurements—consistent with the climate of Guyana's coastal region, with its persistent east northeast winds. Such low sigma theta values are indicative of moderate turbulence—a limiting factor in atmospheric dispersion.

Figure 11 presents the wind rose for New Guyana School during the period of 12 April to 25 August 2019. The predominant wind direction during the monitoring period was from the east-northeast, which was observed approximately 31 percent of the monitoring period. Figures 12 through 14 present the wind roses for the New Guyana School broken down into the Dry #1 monitoring sub-period, the Wet monitoring sub-period, and the Dry #2 monitoring sub-period. The predominant wind directions during the monitoring periods were all from the east-northeast, and were observed 42 percent, 33 percent, and 20 percent of the time for the Dry #1, Wet, and Dry #2 monitoring periods, respectively.



(Wind speed ranges presented in terms of miles per hour)

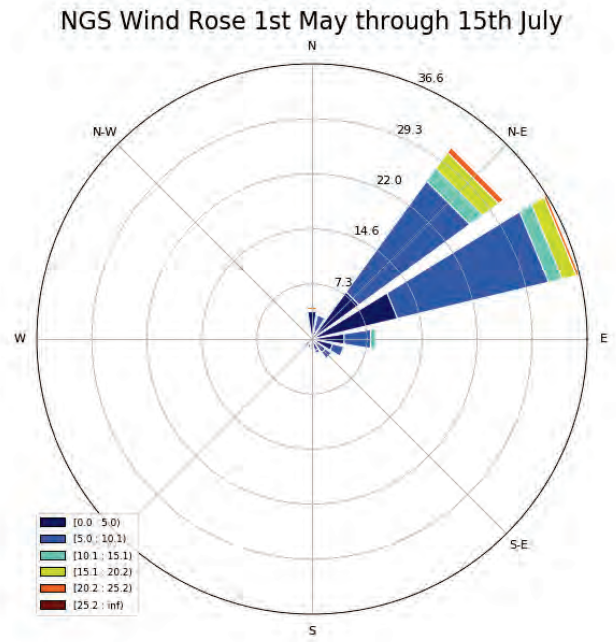
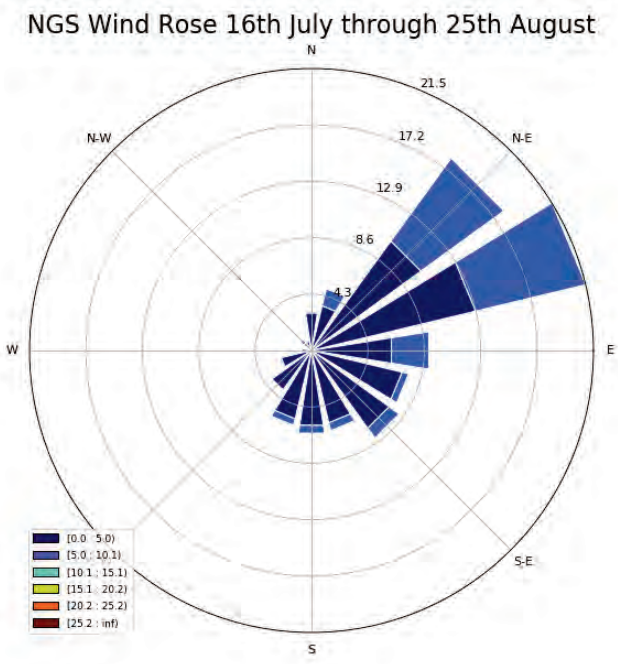
(Wind speed ranges presented in terms of miles per hour)

Figure 12: New Guyana School Wind Rose (Dry #1)



(Wind speed ranges presented in terms of miles per hour)

Figure 13: New Guyana School Wind Rose (Wet)



(Wind speed ranges presented in terms of miles per hour)

Figure 14: New Guyana School Wind Rose (Dry #2)

5. QUALITY CONTROL AND QUALITY ASSURANCE

Various quality assurance and quality control activities were performed during the monitoring periods to evaluate the performance of the monitoring analyzers and to demonstrate conformance to established criteria for data quality. These activities were performed either through automated means or manually, or were inherent to the design of the monitoring system. With the exception of NO_2 at the New Amsterdam monitoring location (discussed below), all measurements demonstrated general compliance with the established quality assurance and quality control criteria.

5.1. Quality Control Results

Automated quality control checks were initiated by the monitoring station's data logger on a weekly basis to assess the performance of the analyzers measuring CO, NO_2, SO_2, and H_2S. These precision checks assess the performance of the analyzer at or below an established air quality standard or near the expected ambient concentration. The precision value is a representation of the repeatability of the analyzer to respond accurately to the control concentration. The bias value is a representation of the analyzer's tendency to respond higher or lower than the control concentration.

Table 26 presents the precision and bias calculations for the four gaseous parameters at the Carifesta monitoring location during the first monitoring period. The results demonstrate that the analyzers were operating well within the acceptance criteria, indicating high quality, reliable data.

Table 26: Carifesta #1 Quality Control Results

Parameter	Valid Challenges	Precision (%)	Bias (%)	Acceptance Criterion (%)
CO	8	8.7	+6.5	± 10%
NO_2	8	1.8	-2.3	± 15%
SO_2	8	3.3	-4.9	± 10%
H_2S	8	4.4	+6.5	± 10%

Table 27 presents the precision and bias calculations for the four gaseous parameters at the New Amsterdam monitoring location. The results of these precision checks demonstrate that the CO and SO_2 analyzers were operating well within the acceptance criteria.

For H_2S, the analyzer passed the precision criterion but exceeded the bias criterion, suggesting that the measured ambient concentrations may be biased high, but the analyzer responded consistently to the changes in ambient concentration. For NO_2, the precision and bias calculations demonstrate that the analyzer was not performing within the acceptance criteria. The degradation in the analyzer's internal pump, which eventually resulted in its failure, significantly affected the analyzer's ability to respond accurately to challenge and ambient concentrations. The NO_2 data collected at the New Amsterdam location, therefore, are of lesser quality and should only be used when qualified as such.

Table 28 presents the precision and bias calculations for the four gaseous parameters at the Carifesta monitoring location during the second monitoring period. The results demonstrate that the analyzers were operating well within the acceptance criteria, indicating high quality, reliable data.

Table 29 presents the precision and bias calculations for the four gaseous parameters at the New Guyana School monitoring location. The results demonstrate that the analyzers were operating well within the acceptance criteria, indicating high quality, reliable data.

Table 27: New Amsterdam Quality Control Results

Parameter	Valid Challenges	Precision (%)	Bias (%)	Acceptance Criterion (%)
CO	6	1.7	+2.8	± 10%
NO_2	6	20.9	-32.5	± 15%
SO_2	6	2.1	+2.9	± 10%
H_2S	6	5.2	+11.2	± 10%

Table 28: Carifesta #2 Quality Control Results

Parameter	Valid Challenges	Precision (%)	Bias (%)	Acceptance Criterion (%)
CO	14	4.3	±4.3	± 10%
NO_2	14	1.5	+5.6	± 15%
SO_2	14	1.6	-2.6	± 10%
H_2S	14	1.7	+4.2	± 10%

Table 29: New Guyana School Quality Control Results

Parameter	Valid Challenges	Precision (%)	Bias (%)	Acceptance Criteria (%)
CO	14	7.6	±6.7	± 10%
NO_2	14	3.7	-5.3	± 15%
SO_2	14	2.0	+3.0	± 10%
H_2S	14	2.9	± 2.4	± 10%

5.2. Quality Assurance

The analyzers measuring PM_{10}, $PM_{2.5}$, CO, NO_2, SO_2, and H_2S are certified by the USEPA for use in assessing ambient air quality. All challenges of the analyzers' performance, manual or automated, were performed in general conformance to accepted quality assurance procedures. The monitoring shelter temperature was maintained within the operational assurance range.

All analyzers were calibrated prior to the start of monitoring at each location. A multipoint quality assurance verification of the analyzers immediately following calibration demonstrated that the analyzers were operating well within the acceptance criteria. With one exception, the multipoint quality assurance verifications were repeated at the conclusion of the monitoring at each location, as long as the analyzer was operational.

At Carifesta during the first monitoring period, these multipoint quality assurance verifications demonstrated that the analyzers were operating within the acceptance criteria.

At New Amsterdam, with the exception of NO_2, these multipoint quality assurance verifications demonstrated that the analyzers were operating within the acceptance criteria. The failure of the NO_2 analyzer prior to the conclusion of the monitoring period did not allow for a multipoint evaluation of the analyzer's performance. A final calibration of the VOC analyzer was not possible following its New Amsterdam deployment due to expected contamination of the calibration gas standard.[7] Nevertheless, data have been validated on the basis of its initial calibration and other quality control checks.

At Carifesta during the second monitoring period, these multipoint quality assurance verifications demonstrated that the analyzers were operating within the acceptance criteria.

The final multipoint quality assurance verifications at the New Guyana School monitoring location demonstrated that the analyzers were operating within the quality assurance criteria. Further quality assurance measures included frequent manual data review (at least twice per week), and monitoring and documenting instrument diagnostic parameters (column temperature, sample flow rate, etc.).

[7] Substantial SO_2 artifact was found in this tank while calibrating the H_2S analyzer. Subsequent challenge of the VOC analyzer showed apparent response shift. Based on these results, it was concluded that the tank had been contaminated with air. Rather than calibrate the VOC analyzer with a standard of uncertain quality, it was decided to rely on the installation calibration for its validation.

µg/m³ = microgram per cubic meter; CO = carbon monoxide; H_2S = hydrogen sulfide; ID = insufficient data; IO = Instrument offline; MM = maintenance mode; NO_2 = nitrogen dioxide; PF = pump failure; $PM_{2.5}$ = fine particulate matter (with aerodynamic diameter of less than 2.5 micrometers); PM_{10} = inhalable particulate matter (with aerodynamic diameter of less than 10 micrometers); PO = power outage; ppb = parts per billion; ppm = parts per million; SO_2 = sulfur dioxide; UM = unknown malfunction; ZS = nightly zero and span

[a] Normal analyzer drift may result in reported negative concentrations where ambient levels are low. In conformance to standard quality assurance practice, these are reported without adjustment.

Acronyms and Abbreviations

Name	Description
$\mu g/m^3$	micrograms per cubic meter
am^3/hr	actual cubic meters per hour
Btu/scf	British thermal units per standard cubic foot
cal/sec	calories per second
CALPUFF	California PUFF model
CFL	Courant–Friedrichs–Lewy
CO	carbon monoxide
CO_2	carbon dioxide
FPSO	Floating Production, Storage, and Offloading (vessel)
EEPGL	Esso Exploration and Production Guyana Limited
ERM	Environmental Resources Management
FDDA	four-dimensional data assimilation
FNL	final analysis
GDAS	Global Forecast System Data Assimilation System
GHG	greenhouse gas
H_2S	hydrogen sulfide
HHV	higher heating value
HP	high pressure
K	degrees Kelvin
LP	low pressure
LSBC	land-sea breeze circulation
LSM	land surface model
mb	millibar
m/s	meters per second
MMBtu/hr	million British thermal units per hour
MMscf/hr	million standard cubic feet per hour
NA	not applicable
NCAR	National Center for Atmospheric Research
NO_2	nitrogen dioxide
NOx	nitrogen oxides
PBL	planetary boundary layer
PM	particulate matter
PM_{10}	particulate matter (aerodynamic diameter less than 10 microns)
$PM_{2.5}$	particulate matter (aerodynamic diameter less than 2.5 microns)
RTG	Real-Time Gridded
SO_2	sulfur dioxide
UTM	Universal Transverse Mercator (East or North)
VOC	volatile organic compound
WHO	World Health Organization
WRF	Weather Research and Forecasting (meteorological model)

1. INTRODUCTION

In support of the Yellowtail Development Project (Project) Environmental Impact Assessment, Esso Exploration and Production Guyana Limited (EEPGL) commissioned Environmental Resources Management (ERM) to perform modeling of air emissions from planned Project activities. The purpose of this modeling was to estimate maximum Project-generated ground-level concentrations at onshore locations where community receptors could be exposed to these concentrations. Additionally, in support of the cumulative impact analysis for the Project, combined emissions from the Project and other reasonably foreseeable EEPGL offshore activities potentially coinciding with the Project were also modeled.

This report provides a description of the modeling methodology—including source characteristics and emissions, receptor locations, model selection, and meteorological data development—and a summary of modeling results. Figure 1-1 displays the modeling domain used in this analysis, showing the locations of the main Project point sources (the Floating Production, Storage, and Offloading vessel [FPSO] and the drill ships supporting the Project), and the boundary of Project-related area sources (including support vessels, construction vessels, and other sources without a fixed location), as configured for the modeling. A single drill ship location was used for modeling all Project drilling activities to provide a conservative estimate of onshore ground-level concentrations (i.e., closest Project drill center to shore). Onshore terrain elevations used in the modeling, as well as other EEPGL offshore activity point sources modeled in support of the cumulative impact assessment, are also depicted.

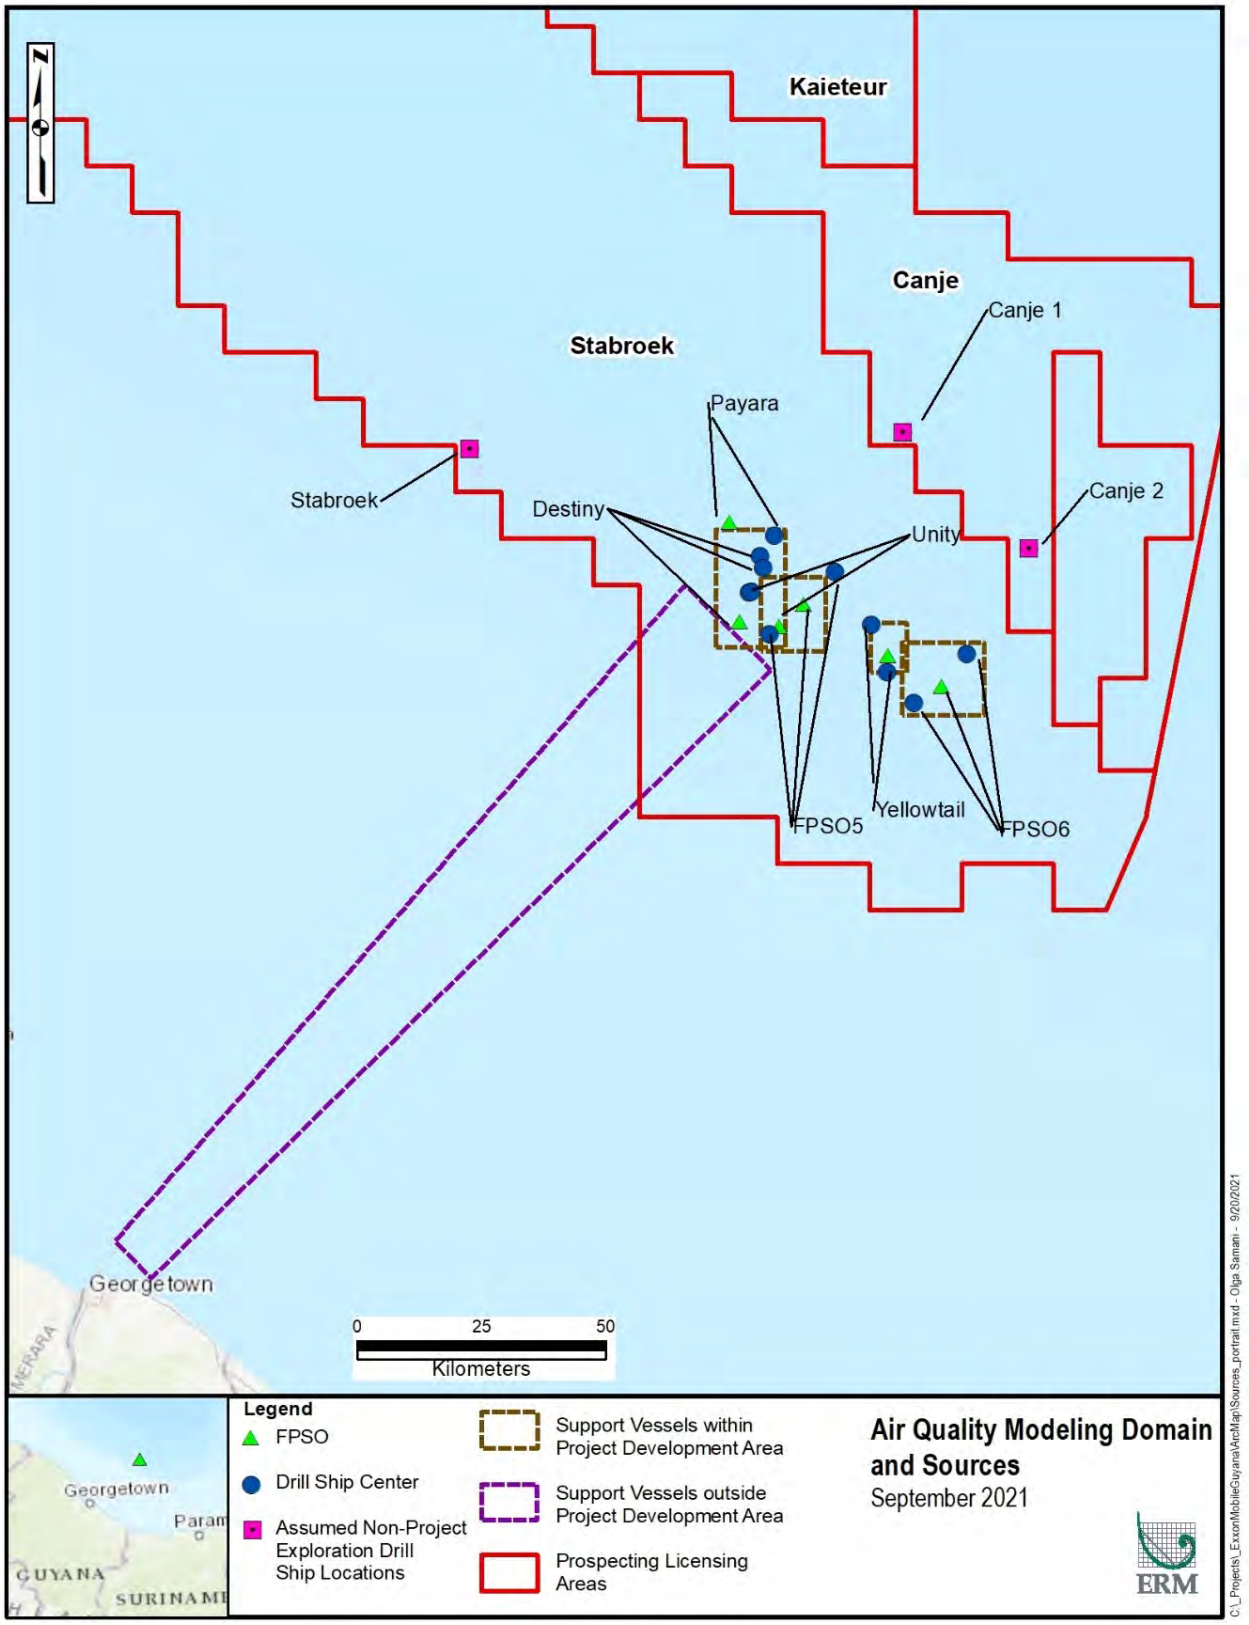

Figure 1-1: Air Quality Modeling Domain

2. AIR QUALITY MODELING METHODOLOGY

2.1 Modeled Activities

Emissions generated by the Project generally emanate from two source categories: (1) specific point sources such as the power-generating units and diesel engines on drill ships and on the FPSO, and flares used (non-routinely) to combust associated gas that is not consumed as fuel gas on the FPSO or re-injected; and (2) general area sources such as support vessels, construction vessels, tug boats, and helicopters.

For the cumulative impact assessment modeling, the following EEPGL offshore activities (in addition to the activities of Yellowtail) were modeled:

- Exploration drilling through end of 2028;
- Liza Phase 1 Development Project (FPSO operation);
- Liza Phase 2 Development Project (FPSO operation);
- Payara Development Project (development well drilling; installation, commissioning, and start-up; and FPSO operation);
- A fifth development project (referred to herein as “FPSO #5”; development well drilling; installation, commissioning, and start-up; and FPSO operation); and
- A sixth development project (referred to herein as “FPSO #6”; development well drilling; installation, commissioning, and start-up; and FPSO operation).

The specific source emissions modeled for these other EEPGL offshore activities were selected based on their currently forecasted timing (and assumed locations, in the case of exploration drilling) relative to that of the Project. Figure 2-1 presents the cumulative impact assessment basis used for this purpose.

With respect to other EEPGL activities assessed as part of the cumulative impact assessment, the cumulative impact assessment modeling excluded emissions from the Guyana Fiber Optic Enablement Project and Guyana Office Complex Project because the anticipated emissions from these projects are expected to be *de minimis* in comparison to those from the EEPGL development projects. The cumulative impact assessment modeling excluded emissions from the Gas to Energy (GTE) Project because the specific equipment for the GTE Project has not yet been determined. Emissions associated with the GTE Project will be modeled (together with cumulative emissions from other EEPGL activities, as appropriate) as part of the EIA that will be prepared separately for that project.

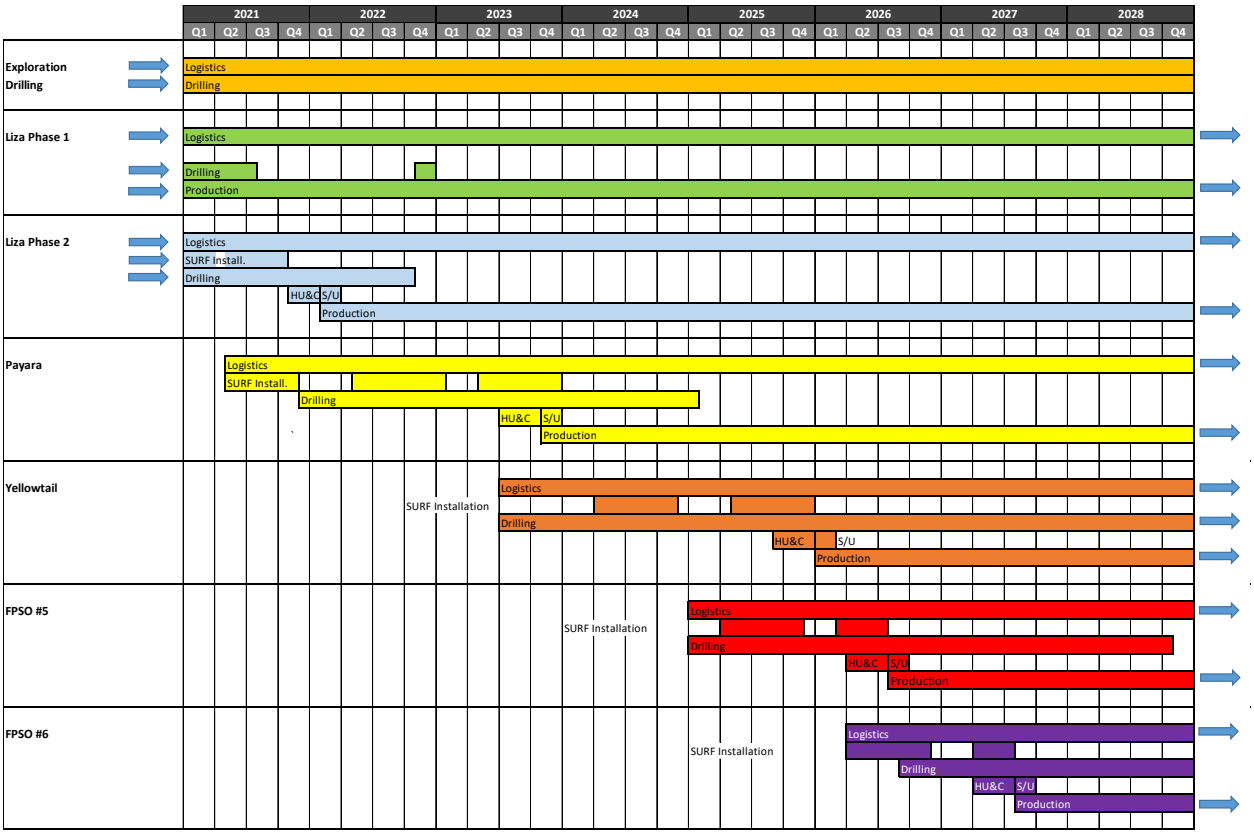

Figure 2-1: Cumulative Impact Assessment Basis for EEPGL Offshore Activities

2.2 Model Inputs: Source Characteristics and Emissions

Modeling “stack” sources involves first calculating plume rise (i.e., how high the plume rises due to momentum and buoyancy of the release). Plume rise is added to the physical stack height to determine final plume height, and the plume is tracked as it is transported downwind and dispersed by atmospheric turbulence. Stack parameters needed for model input include the physical stack height, internal diameter, exhaust velocity, elevation of the base of the stack, and exhaust temperature.

Table 2-1 displays the values for the Project parameters used in this analysis, along with the stack locations in Universal Transverse Mercator (UTM) coordinates. Table 2-1 also displays Project area source characteristics used for the modeling. These values are based on current knowledge of the Project design. It is noted that, due to the distance from Project sources to potential onshore receptors, modeled concentrations are not very sensitive to changes in stack parameters.

Table 2-1 also represents the parameters used for modeling the other five offshore EEPGL activities included in the cumulative impact assessment modeling, adjusted for locations as appropriate. Modeled locations for EEPGL activities are displayed on Figure 1-1.

Flares associated with the Project were modeled as point sources, with adjustments made to account for and maintain buoyancy of the hot plume. Table 2-2 displays the inputs and results of the calculations that were conducted to estimate an effective diameter and an effective stack height that accomplishes this goal. These parameters were used for all modeling that was conducted for non-routine flaring associated with the Project and for other EEPGL activities included in the cumulative impact assessment modeling, adjusted for locations as appropriate.

Table 2-1: Stack Parameters for Model Input

Name	UTM-E [a]	UTM-N [a]	Base Elevation	Height Above Base Elevation	Exhaust Flow	Exhaust Temp	Diameter	Exhaust Velocity
	meters	meters	meters	meters	am^3/hr	K	meters	m/s
FPSO Sources

Helicopters between Shore and Project Development Area	Note c		0	300.00	NA	NA	NA	NA
General Project Development Area (Installation)	Note d Note e		0	10.00	NA	NA	NA	NA

am^3/hr = actual cubic meters per hour; HP = high pressure; K = degrees Kelvin; LP = low pressure; m/s = meters per second; NA = not applicable; UTM-E = Universal Transverse Mercator East; UTM-N = Universal Transverse Mercator North, Zone 21N, WGS84.
[a] Coordinates listed are for Yellowtail Project sources.

[b] Effective height/diameter calculated based on heat release to maintain buoyancy flux; physical height above base elevation is 134 meters.

[c] Area sources assumed to distribute emissions evenly between shore and Project Development Area.
[d] General area source in Project Development Area.
[e] Includes planned Project installation activities in the PDA.

Table 2-2: Flare Calculations

Description	Gas Usage	Gas HHV	Total Heat Release	Total Heat Release	Sensible Heat Release	Effective Stack Diameter [a]	Physical Stack Height	Effective Stack Height [a]
	MMscf/hr	Btu/scf	MMBtu/hr	cal/sec	cal/sec	meters	meters	meters
Non-Routine Flaring								
Flare	0.30	1,707.4	519.6	3.64E+07	1.64E+07	4.0	134	153.0

Btu/scf = British thermal units per standard cubic foot; cal/sec = calories per second; HHV = higher heating value; MMBtu/hr = million British thermal units per hour; MMscf/hr = million standard cubic feet per hour
[a] Effective diameter and effective stack height calculated based on U.S. Environmental Protection Agency guidance, using 20 meters per second exit velocity and 1,273 K exhaust temperature.

Emissions to air from the Project have been estimated based on a number of factors including activity levels, fuel types, equipment capacities, and standard emission factors that are published by the U.S. Environmental Protection Agency in the publication *AP-42: Compilation of Air Pollutant Emission Factors* (AP-42; USEPA Undated). As described in AP-42, an emission factor is a representative value that relates the quantity of a pollutant released to the atmosphere with an activity associated with the release of that pollutant. These factors are usually expressed as the weight of pollutant divided by a unit weight, volume, distance, or duration of the activity emitting the pollutant (e.g., milligrams of nitrogen oxides [NO_x] emitted per cubic meter of natural gas combusted). In most cases, these factors are averages of available data of an acceptable quality, and are generally assumed to be representative of long-term averages for a particular type of source (AP-42; USEPA Undated).

Table 2-3 provides a summary of expected annual emissions from various planned Project activities for three time periods: 2023–2024 (development well drilling; Subsea, Umbilicals, Risers, and Flowlines [SURF] installation and commissioning; FPSO installation; and operation of related support vessels); 2025–2027 (continued development well drilling; operation of related support vessels; FPSO start-up and associated temporary, non-routine flaring; beginning of production operations; and tanker loading); and 2028–2044 (production operations following start-up, including temporary, non-routine flaring; potential continued development well drilling; operation of related support vessels; and tanker loading). For each of the time periods, the annual emissions presented in Table 2-3 for each pollutant other than non-methane volatile organic compounds (VOCs) and greenhouse gases (GHGs) represent the maximum anticipated annual emissions for each source during the time period. These source-specific maximum values are not necessarily all from the same year in the time period. While there are some differences in pollutant emissions for different years within the time periods, they are relatively minor and the use of maximum emissions for the impact assessment provides a degree of conservatism in the results. In the case of non-methane VOCs, the source-specific emissions for each time period are all from the same year (i.e., 2024, 2026, and 2029). In the case of GHGs, the source-specific emissions for the first two time periods are all from the same year within the time period (i.e., 2024 and 2026). These are the years with the maximum anticipated annual GHG emissions for any of the years during the respective time periods. For the third time period, the GHG emissions are the average annual emissions across the time period.

The Project emissions estimates account for an assumed quantity of emissions from low-level continuous flaring of pilot gas, purge gas, and other *de minimis* streams described in Chapter 2, Description of the Project, as well as temporary, non-routine flaring associated in part with upsets and maintenance, and other non-routine and/or unplanned events during the Project life cycle. Estimated emissions from non-routine flaring are included together with estimated emissions from planned activities. These estimated emissions account for a reduced duration of flaring during these non-routine events as a result of the additional compression sparing that has been included in the Project design. With respect to start-up, the Project is targeting 60 cumulative days for start-up flaring, recognizing that this would represent industry-leading performance. For the purpose of modeling, the estimated emissions are based on the conservative assumption that start-up flaring for the Project will be temporary and may require flaring for 90 cumulative days at the rate of 120 million standard cubic feet per day (MMscfd). In the United States offshore, flaring may occur for up to 1 year with regulatory approval (30 Code of Federal Regulations §250.1161): “[An operator] must request and receive approval from the Regional Supervisor to flare or vent gas for an extended period of time. The Regional Supervisor will specify the approved period of time, which will not exceed 1 year.”

Table 2-3: Annual Air Emissions Summary—Yellowtail Project

Pollutant	Source Category	Design Case			Modeled Case		
		Maximum Annual Emissions (tonnes) [a,c]			Maximum Annual Emissions (tonnes) [a,c]		
		2023–2024	2025–2027	2028–2044 [f]	2023–2024	2025–2027	2028–2044 [f]

	Total	1,055	3,505	2,050	1,055	3,565	2,775
Hydrogen Sulfide	FPSO Flaring (temporary, non-routine)	NA (no emissions)	<5	<1	NA (no emissions)	<5	<1

Pollutant	Source Category	Design Case			Modeled Case		
		Maximum Annual Emissions (tonnes) [a,c]			Maximum Annual Emissions (tonnes) [a,c]		
		2023–2024	2025–2027	2028–2044 [f]	2023–2024	2025–2027	2028–2044 [f]
Non-methane Volatile Organic Compounds (VOCs) [e]	All Sources	30	3,500	2,370	30	3,555	2,955
Greenhouse Gases (GHGs) (kilotonnes carbon dioxide-equivalents) [e,g]	All Sources	240	1,730	1,110	240	1,760	1,395

NA = not applicable
[a] The annual estimated totals generally reflect the current preliminary Project schedule and production profile and remain subject to adjustment. Source category-specific sub-totals are rounded up to the next 5 tonnes and the totals reflect the sum of the rounded sub-totals.
[b] PM emissions represent total PM; for the purpose of the impact assessment, the results from modeling of total PM values were used for comparison to both PM_{10} standards and $PM_{2.5}$ standards (a conservative assumption).
[c] The emission rates in this table reflect annual totals. In some cases, the activities generating the emissions are not continuous during the year, or do not operate at full capacity throughout the year. For these sources, the annual emissions reflect this non-continuous operation over the year. However, for the purpose of modeling conducted to compare with short-term (up to 24-hour) guidelines, activities were assumed to be operating at full capacity for the simulated period to reflect maximum possible short-term emission rates.
[d] Area Sources are mobile equipment such as aviation and marine support vessels (besides the FPSO and drill ships) used during drilling; installation, commissioning, and start-up; production operations; and decommissioning.
[e] Total non-methane VOC and GHG emissions are shown in this table but were not modeled, as there are no ambient air quality criteria for total non-methane VOC emissions.
[f] Development well drilling could occur for up to 5 years into the period.
[g] Estimated GHG emissions for 2028-2044 period represent average of estimated annual emissions for years 2028 to 2044.

Table 2-4: Annual Air Emissions Summary—Cumulative EEPGL Offshore Activities (Including Yellowtail Emissions)

Pollutant	Source Category	Design Case [a,c]			Modeled Case [a,c]		
		Annual Emissions (Tonnes)			Annual Emissions (Tonnes)		
		2023-2024	2025-2027	2028-2044 [e]	2023-2024	2025-2027	2028-2044 [e]
Nitrogen Oxides (NOx)	All Sources	22,020	22,880	24,505	22,020	22,895	24,770
Sulfur Dioxide (SO_2)	All Sources	1,540	1,380	1,285	2,235	1,385	1,330
Particulate Matter (PM) [b]	All Sources	1,040	1,395	1,205	1,115	1,400	1,235
Carbon Monoxide (CO)	All Sources	6,555	13,185	12,105	6,690	13,190	13,065
Hydrogen Sulfide (H_2S)	All Sources	10	10	5	3,170	10	5
Total Non-methane VOCs [d]	All Sources	20,955	19,325	18,860	20,955	19,380	19,545
Greenhouse Gases (kilotonnes CO_2-equivalents)	All Sources	5,635	5,905	7,815	5,635	5,935	8,710

CO_2 = carbon dioxide
[a] The annual estimated totals generally reflect the current preliminary Project schedule and production profile and remain subject to adjustment. Source category-specific sub-totals are rounded up to the next 5 tonnes and the totals reflect the sum of the rounded sub-totals.
[b] PM emissions represent total PM; for the purpose of the impact assessment, the results from modeling of total PM values were used for comparison to both PM_{10} standards and $PM_{2.5}$ standards (a conservative assumption).
[c] The emission rates in this table reflect annual totals. In some cases, the activities generating the emissions are not continuous during the year, or do not operate at full capacity throughout the year. For these sources, the annual emissions reflect this non-continuous operation over the year. However, for the purpose of modeling conducted to compare with short-term (up to 24-hour) guidelines, activities were assumed to be operating at full capacity for the simulated period to reflect maximum possible short-term emission rates.
[d] Total non-methane VOC and GHG emissions are shown in this table but were not modeled, as there are no ambient air quality criteria for total non-methane VOC emissions.
[e] Development well drilling could occur for up to 5 years into the period.

Emissions estimates are provided for two cases designated as the “Design Case” and “Modeled Case.” The Design Case emissions are based on estimated annual flaring, including an estimate of non-routine flaring in accordance with design basis assumptions for the Project. The Modeled Case emissions include an additional contingency for non-routine flaring volumes and are considered to reflect a credible worst case for non-routine flaring. Operational reliability performance is best described as a range of experience. Recognizing that range, a “low side” and “high side” estimation has been included to demonstrate the potential range for experience. For the purposes of modeling, only the High Case emissions estimates are assessed – reflecting the reasonable worst-case resulting ambient onshore concentrations of pollutants.

2.3 Receptors

A grid of potential receptor points was established for onshore areas, with a denser grid used in coastal areas (closer to the sources) and a coarser grid used in inland regions. For each pollutant, dispersion modeling was used to predict the maximum ground-level concentration at any time at any one of the onshore grid points; these maximum predicted concentrations were then compared to ambient air quality guidelines. Under this conservative approach, if the maximum predicted concentrations are determined to be less than the respective ambient air quality guidelines, it follows that ambient air quality guidelines would be met at any specific onshore receptor location. For this reason, specific locations of sensitive receptors were not identified at the onset of modeling. Figure 2-2 illustrates the potential receptor location grid used. At each potential receptor grid node, terrain elevations were specified and used by the California PUFF model (CALPUFF) to model plume interaction with onshore terrain.

2.4 Model Selection

The CALPUFF model (Version 7.3.2, level 200113) used in the assessment is a non-steady-state model used in the United States and around the globe for long-range transport and complex wind modeling. CALPUFF is a Lagrangian “puff” model that treats a plume as a series of puffs that it tracks as the wind carries the plume toward potential receptor locations. The selection of CALPUFF was based on the relatively large distance between the Project Development Area and the potential onshore receptors. The distance from the Project Development Area to the coastline of Georgetown is approximately 203 kilometers (126 miles). At this distance, emission plumes released from the point sources modeled would travel for approximately 10 hours before reaching the Guyana shoreline, assuming an average wind speed of 5 meters (16.4 feet) per second (typical for the area). During this transport time, winds can change direction and speed. Accordingly, prediction of plume dispersion is most appropriately accomplished with a non-steady state model. Additionally, due to the vast differences in surface characteristics between open water and land, coastal areas frequently experience a classic meteorological phenomenon known as the land-sea breeze circulation (LSBC). This phenomenon is due to the diurnal surface temperature differences that develop between the land and the open water. LSBC effects can play an important role in the dispersion modeling analysis of emission sources as plumes interact with onshore receptors. CALPUFF, combined with gridded meteorological data, is capable of accounting for the LSBC phenomenon. CALPUFF was run for each source individually and post-processing was used to calculate pollutant-specific totals for applicable averaging periods.

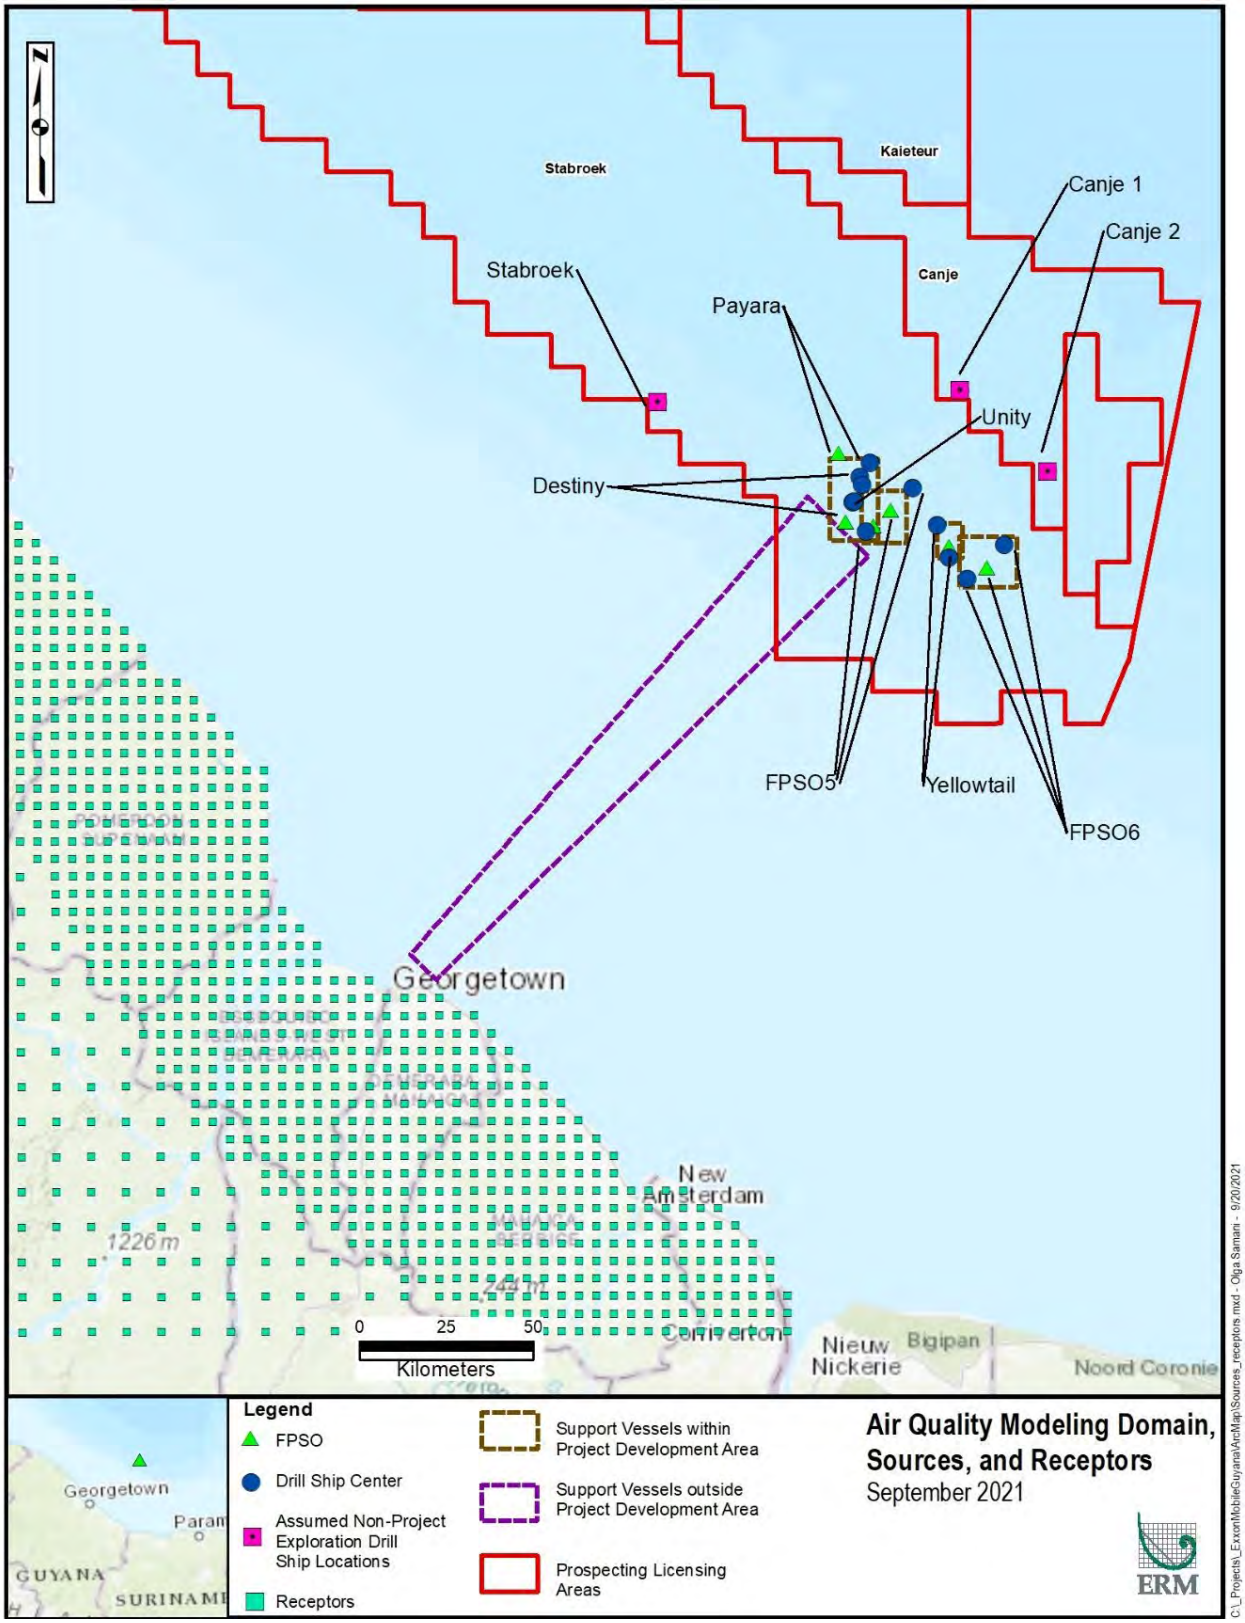

Figure 2-2: Receptor Grid Used for Air Quality Modeling

2.5 Meteorological Data

2.5.1 WRF Model Configuration

The Weather Research and Forecasting (WRF) model (WRF-ARW, Version 4.0; Skamarock 2019) was used to develop a simulated meteorological data set for the air quality modeling because there is limited suitable observational data available for the region. A full three-dimensional grid of WRF-simulated meteorological data was used for the CALPUFF simulations. These data include simulated meteorological conditions across the modeling domain at a resolution of 9 kilometers (5.6 miles). Observational data from 2017 through 2019 were used as input for the WRF model. This period was simulated to identify the worst-case dispersion conditions (i.e., leading to the maximum predicted onshore concentrations) that would be expected during the Project lifecycle. The WRF model is a state-of-the-science numerical meteorological model that is designed to simulate atmospheric systems on a wide range of spatial and temporal scales.

WRF is a widely used three-dimensional numerical meteorological model with a terrain following, hydrostatic pressure vertical coordinate. The model contains non-hydrostatic dynamics, and a variety of physics options for parameterizing moist convection, cloud microphysics, the planetary boundary layer (PBL) turbulence physics, atmospheric radiation, and land surface models (LSMs). The model is designed for simulating atmospheric phenomena across scales ranging from large eddies (~100 meters [328.1 feet]) to mesoscale circulations and waves (from ~100 meters [328.1 feet] to 1,000 kilometers [621.4 miles]) to synoptic-scale weather systems (>1,000 kilometers [>621.4 miles]). It is also used to generate three-dimensional gridded meteorological data (such as hourly wind and temperature fields) in the modeling domain through the treatment and assimilation of available surface and upper air observations. The methodology that was followed for the WRF modeling is described below.

WRF static geophysical data are available from the National Center for Atmospheric Research (NCAR) for terrain, vegetation/land use, land mask, soil moisture, and soil type. NCAR distributes various resolutions of global terrain and land-use databases to support WRF simulations. The databases are:

- 5-minute (about 9.25 kilometers [5.75 miles) in mid-latitudes)
- 2-minute (about 4.00 kilometers [2.5 miles] in mid-latitudes)
- 30-sec (about 0.900 kilometers [0.6 miles] in mid-latitudes)

These data are assigned to WRF simulations based on the resolution of the simulation domain. These data were used to develop the GEOGRID files on static terrain and land use data for the model simulations.

The WRF-ARW model was configured with multiple nested grids to achieve a grid resolution capable of resolving the land use and terrain characteristics of the Guyana region, as well as the meteorology over the ocean. A Mercator projection was used, which is suitable for simulations in the low-latitude tropics. The Mercator projection uses a reference latitude/longitude of 6.71 degrees north and 55.00 degrees west. Figure 2-3 shows the complete domain configuration used in the WRF simulations. The model used a large outer domain (Domain 1) at a grid resolution of 27 kilometers (16.8 miles) spanning the central and eastern portions of northern South America and over the Atlantic Ocean. This domain extent is necessary to properly simulate the evolution of larger-scale atmospheric features. Domain 2 consists of a smaller domain with a grid resolution of 9 kilometers (5.6 miles). This domain extends over the northeast portion of South America and east over the tropical Atlantic Ocean, encompassing the offshore Guyana area in which modeled activities occur.

Figure 2-3: WRF Model Domain Configuration

To properly depict the vertical structure of the atmosphere, WRF uses a mass-based terrain-following vertical coordinate system referred to as the eta (ŋ) coordinate system. This coordinate system is essentially the same as the sigma terrain-following coordinate used in WRF's predecessor model (MM5). The WRF simulations employed 40 eta vertical levels from the surface up to 50 millibars (mb). The vertical levels used in the WRF modeling are also shown in Table 2-5. Table 2-5 shows the WRF eta layer values and the layer and mid-layer heights.

Table 2-5: Vertical Layers Used in the WRF Simulations

Level No.	ETA Level	Layer Height (m)	ETA Half-Level	Mid Layer Height (m)		Level No.	ETA Level	Layer Height (m)	ETA Half-Level	Mid Layer Height (m)

Initial and lateral meteorological boundary conditions are provided to the WRF Preprocessing System as the initial data, both spatially and temporally, at the start of the WRF simulation. In general, initialization data sets are assimilated with a great deal of observational data, which include surface pressure, sea level pressure, geopotential height, temperature, sea surface temperature, soil values, ice cover, relative humidity, u and v wind components, vertical motion, vorticity, winds and in-situ data such as moisture from radiosondes and pressure from surface observations. Also included in these data sets are precipitation data, profiler data, dropsondes, pibals, aircraft temperatures and winds, land surface and moisture data, and cloud drift winds from geostationary satellites. There are numerous analysis datasets available to use with WRF at various spatial and temporal resolutions.

The WRF simulations for the modeling used the National Oceanic and Atmospheric Administration Global Forecast System Data Assimilation System (GDAS) 6-hourly final analysis (FNL) files at 0.25-degree resolution. The 1/12th degree resolution sea surface temperature data used were sourced from the Real-Time Gridded (RTG) data archive. Because the RTG data archive was terminated in late November 2019, the remainder of the 2019 WRF simulation period uses the skin temperature data from the GDAS analysis files.

2.5.2 Selected WRF Physics Suite

The WRF model was run using the Thompson microphysics scheme to account for cloud microphysical processes. The Thompson scheme accounts for snow, ice and graupel processes and it is suitable for high-resolution simulations. Atmospheric radiation processes for both short-wave and long-wave radiation are handled with the Rapid Radiative Transfer Model for Global Climate Models scheme. Land surface processes were presented using the MM5 Monin-Obhukov surface layer physics, the Noah unified LSM, and the Yonsie University PBL scheme physics. Both the outer 27-kilometer (16.8-mile) and 9-kilometer (5.6-mile) resolution domains (Domains 1 and 2) used the Tiedtke cumulus physics scheme to parameterize moist convection. The Tiedtke scheme was chosen since modeling studies using this scheme have shown good overall performance over the tropical latitude belt globally. The surface

physics, LSM, and PBL schemes chosen are generally well tested over many simulations in different geographical regions.

The WRF simulations initially showed problems with Courant–Friedrichs–Lewy (CFL) violations suggesting the vertical velocities were too large. Often this is caused by steep terrain slopes. However, an examination of the locations of the CFL violations[1] at specific grid cells showed a concentration of these in the upper layers of the model domain even over relatively flat terrain. This suggested that gravity wave activity at the top of the model domain may be responsible. Thus, the option to implement vertical velocity damping coupled with gravity wave damping was implemented. These settings resolved the CFL problems.

2.5.3 Four Dimensional Data Assimilation

The WRF modeling system also has four-dimensional data assimilation (FDDA) capabilities. FDDA is a method of performing WRF simulations with the full-physics model while blending local observations. By doing so, model equations maintain dynamic consistency while at the same time restraining the model's solutions from deviating too strongly from observations or a gridded analysis and make up for errors and gaps in the initial analysis and deficiencies in model physics. There are two types of what is known as "FDDA nudging" in WRF:

- ***Analysis nudging***—which gently forces the model solution toward gridded fields and also makes use of three-dimensional analyses and surface analyses.
- ***Observation nudging ("obs nudging")***—which gently forces the model solution toward individual observations, with the influence of the observations spread in space and time.

Meteorological observations from both upper air and the surface were included in the WRF FDDA simulation. Upper Air Observational Weather Data are composed of weather reports from radiosondes, pibals, and aircraft reports from the Global Telecommunications System and satellite data from the National Environmental Satellite Data and Information Service[2]. This dataset includes pressure, geopotential height, air temperature, dew point temperature, wind direction, and speed. Data may be available at up to 20 mandatory levels ranging from 1,000 mb to 1 mb, plus a few significant levels. Report intervals range from hourly to every 12 hours. Surface meteorological data[3] include variables such as pressure, air temperature, dew point temperature, and wind direction and speed at the ground level. Report intervals range from hourly to every three hours.

The WRF simulations implemented both analysis nudging and observation nudging on the outer largest domain (Domain 1) and observation nudging only on Domain 2. The analysis nudging was performed using the FNL 0.25-degree analysis data. Additionally, nudging moisture and temperature in the PBL was not performed. This is a common practice to prevent the nudging process from eroding important simulated temperature and moisture profiles within the PBL.

2.5.4 WRF Analysis

Inspection of the WRF 10-meter (32.8-foot) wind fields was performed at various points during the WRF simulations to ensure reasonable representation of the meteorology by the model. Overall, the WRF model represented the meteorology and the diurnal cycle reasonably well.

[1] A CFL condition is a necessary condition for convergence while solving certain partial differential equations numerically by the method of finite differences. WRF develops numerical instability, CFL errors, that cause high-resolution runs (not always necessary) to fail occasionally.

[2] http://rda.ucar.edu/datasets/ds351.0/index.html

[3] http://rda.ucar.edu/datasets/ds461.0/index.html

To develop more specific climate information regarding onshore climate conditions, EEPGL commissioned deployment of a meteorological station at a site in Carifesta where ambient onshore monitoring air quality data were being collected. The meteorological station collected hourly meteorological data from February 2018 through April 2019. This site was situated on the immediate shoreline but was surrounded by built-up and urban land used adjacent to the station and extending inland for some distance. The initial wind roses showed that the WRF model had a negative wind bias at the station location (i.e., simulated winds speeds were lower than observed). However, the wind directions are dominated by northeast flow, characteristic of the northeast trade winds. As a result, a grid cell slightly offshore was selected and this showed simulated wind speeds more similar to the observed data at the Georgetown station. Figure 2-4 shows two wind roses showing a comparison of the WRF-predicted and observed data. Figure 2-4 shows that for the WRF-predicted wind rose, there are somewhat higher wind speeds than observed. This appears to be due to the lower surface roughness in the offshore grid cell selected. The actual meteorological station sits on land adjacent to the coastline. These discrepancies are related to how well the coastal boundary and associated surface roughness is represented in the WRF grid resolution used. The wind roses show a relatively small wind direction bias such that WRF has a bit more northeast and east-northeast winds than observed. Overall, this wind rose shows that the WRF simulations are representing the overall wind distribution reasonably well.

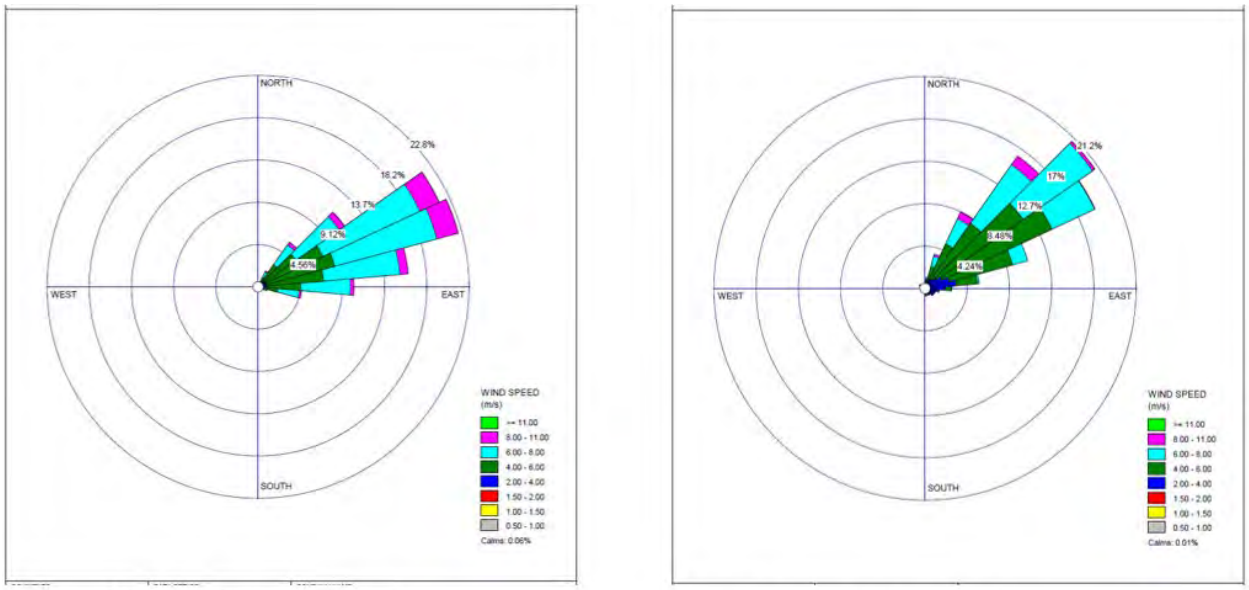

Figure 2-4: WRF-Predicted and Observed Wind Roses at Georgetown

Figure 2-5 shows two wind field plots on the 9-kilometer (5.6-mile) domain at two different dates. These plots show an example of the WRF-simulated 10-meter (32.8-foot) wind field. The northeast trade wind flow is clearly shown, with speeds on the order of 6 to 10 meters per second (19.7 to 32.8 feet per second) over the ocean. This is consistent with trade wind climatology. Also, note the reduction of wind speed as the flow crosses the coastline due to increased surface roughness and associated surface drag.

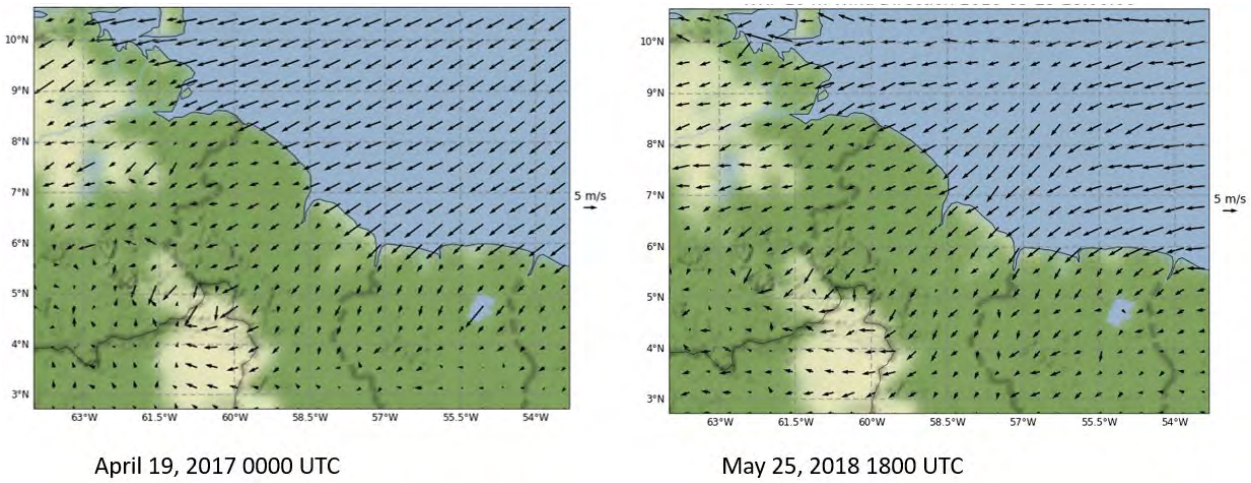

Figure 2-5: WRF-simulated 10-Meter (32.8-Foot) Wind Fields for 19 April 2017 and 25 May 2018

3. RESULTS

3.1 Ambient Air Quality Guidelines

Ambient air quality guidelines are concentration levels in air that are established to protect human health in locations where exposure can potentially occur. These generally include a margin of safety to ensure that vulnerable individuals are also protected. Guyana has not established specific ambient air quality standards; therefore, the guidelines used for reference in this assessment are those established by the World Health Organization (WHO) and the U.S. Environmental Protection Agency (USEPA). WHO guidelines can be found in the WHO Air Quality Guidelines for Particulate Matter, Ozone, Nitrogen Dioxide and Sulfur Dioxide—Global Update 2005 (WHO 2005) and the more recent WHO Global Air Quality Guidelines (WHO 2021), except for hydrogen sulfide (H_2S) for which WHO guidelines were published in the WHO Air Quality Guidelines for Europe, 2nd edition (WHO 2000). The current USEPA National Ambient Air Quality Standards (NAAQS) as of 1 October 2021 are summarized in USEPA 2021. The ambient air quality guidelines considered for assessment of existing conditions and the cumulative impact assessment are summarized in Table 3-1.

The WHO 2000 and WHO 2005 guidelines do not specify a “ranking” for values to be compared to short-term (10-minute to 8-hour) guidelines (e.g., the highest value, the second highest value, etc.); accordingly, the maximum observed or modeled concentration is used for comparison to WHO 2000 and WHO 2005 guidelines. Modeling for 1-hour standards involves predicting concentrations for every hour of the year; this means that out of 8,760 concentration predictions per modeled year, the single highest value is used for comparison to a WHO 2005 1-hour guideline. By contrast, the WHO 2021 and USEPA NAAQS guidelines employ a statistically based metric for comparison to some guidelines (e.g., the 98th percentile value for 1-hour NO_2; the 99th percentile value for 24-hour NO_2; the 99th percentile value for 1-hour SO_2). For the air quality modeling presented herein, the WHO 2005 guideline and the USEPA

NAAQS guideline for 1-hour NO_2 are both used for comparison purposes; the USEPA NAAQS guideline provides a more robust comparison that does not assess the single highest hourly value, while the WHO 2005 guideline considers the single highest hourly value—effectively representing an extreme upper bound estimate. Similarly, the WHO guideline and the USEPA NAAQS guideline for 24-hour PM_{10} and $PM_{2.5}$ are both used for comparison purposes. For each pollutant and averaging time, if more than one guideline for a given averaging period is listed in the table above (e.g., annual average $PM_{2.5}$), the lowest was used in the assessment.

Table 3-1: Ambient Air Quality Guidelines Considered in the Assessment

Pollutant	Averaging Period	Guideline Concentration (µg/m³ except as noted)			
		WHO 2000	WHO 2005	WHO 2021	USEPA 2021
NO_2	1-hour[j]	-	200	-	-
	1-hour (98th percentile)[a]	-	-	-	188 (100 ppb)
	24-hour (99th percentile)[b]	-	-	25	-
	Annual [f]	-	-	10	100 (53 ppb)
SO_2	10-minute[h]	-	500	-	-
	1-hour (99th percentile)[c]	-	-	-	196 (75 ppb)
	24-hour (99th percentile)[b]	-	-	40	-
PM_{10}	24-hour (99th percentile)[b]	-	-	45	-
	24-hour (second high)[g]	-	-	-	150
	Annual [f]	-	-	15	-
$PM_{2.5}$	24-hour (99th percentile)[b]	-	-	15	-
	24-hour (98th percentile)[d]	-	-	-	35
	Annual	-	-	5[f]	12[e]
CO	15-minute[i]	-	100,000	-	-
	1-hour	-	35,000[j]	-	40,000 (35 ppm)[l]
	8-hour	-	10,000[k]	-	10,000 (9 ppm)[m]
	24-hour (99th percentile)[b]	-	-	4,000	
H_2S	24-hour[n]	150	-	-	-

µg/m³ = micrograms per cubic meter; CO = carbon monoxide NO_2 = nitrogen dioxide; PM_{10} = particulate matter (aerodynamic diameter less than 10 microns); $PM_{2.5}$ = particulate matter (aerodynamic diameter less than 2.5 microns); ppb: parts per billion; ppm: parts per million; SO_2 = sulfur dioxide
[a] Average of the 98th percentile 1-hour average concentrations for each of the modeled years.
[b] Maximum of the 99th percentile 24-hour average concentrations across all modeled years.
[c] Average of the 99th percentile 1-hour average concentrations for each of the modeled years.
[d] Average of the 98th percentile 24-hour average concentrations for each of the modeled years.
[e] Average of the annual average concentrations for each of the modeled years.
[f] Maximum of the annual average concentrations across all modeled years.
[g] Maximum of the second-highest 24-hour average concentrations across all modeled years.
[h] Maximum of the 10-minute average concentrations across all modeled years.
[i] Maximum of the 15-minute average concentrations across all modeled years.
[j] Maximum of the 1-hour average concentrations across all modeled years.
[k] Maximum of the 8-hour average concentrations across all modeled years.
[l] Maximum of the second-highest 1-hour average concentrations across all modeled years.
[m] Maximum of the second-highest 8-hour average concentrations across all modeled years.
[n] Maximum of the 24-hour average concentrations across all modeled years.

3.2 Assessment of Existing Airshed

To support interpretation of the result of air dispersion modeling, the guidelines shown in Table 3-1 were used to characterize existing conditions in the ambient airshed. As part of a prior study, EEPGL facilitated measurement of ambient onshore air concentrations of various pollutants at three locations in Guyana (Carifesta, New Amsterdam, and New Guyana School). For each of the parameters subjected to modeling and each of the averaging periods for which a guideline is provided in Table 3-1, Table 3-2 shows the maximum measured concentrations for the same averaging periods. These measured concentrations were developed based on combining the separate monitoring campaigns into a single data set (i.e., combining data from the three ambient air quality monitoring sites). These maximum measured concentrations were used to represent the existing ambient air concentrations where an onshore receptor could potentially be located.

Table 3-2: Summary of Maximum Measured Baseline Ambient Air Concentrations

Pollutant	Averaging Period	Maximum Concentration ($\mu g/m^3$)	Applicable Guideline ($\mu g/m^3$)
Nitrogen dioxide (NO_2)	1-hour	40.8[j] / 24.1[a]	200[j] / 188[a]
	24-hour	9.4	25[b]
	Full Period (318 days)	1.1	10[f]
Sulfur dioxide (SO_2)	10-minute	38.7	500[h]
	1-hour	18.9	196[c]
	24-hour	4.7	40[b]
Particulate matter (PM_{10})	24-Hour	154.3[b] / 140.4[g]	45[b] / 150[g]
	Full Period (320 days)	25.9	15[f]
Particulate matter ($PM_{2.5}$)	24-Hour	53.1[b] / 21.6[d]	15[b] / 35[d]
	Full Period (320 days)	9.6	5[f]
Carbon monoxide (CO)	15-minute	2,767	100,000[i]
	1-hour	1,660[n]/1,562[k]	35,000[j]/40,000[k]
	8-hour	1,316[n]/1,156[m]	10,000[l]/10,000[m]
	24-hour	905	4,000[b]
Hydrogen sulfide (H_2S)	24-hour	22.3	150[o]

[a] Average of the 98th percentile 1-hour average concentrations for each of the modeled years.
[b] Maximum of the 99th percentile 24-hour average concentrations across all modeled years.
[c] Average of the 99th percentile 1-hour average concentrations for each of the modeled years.
[d] Average of the 98th percentile 24-hour average concentrations for each of the modeled years.
[e] Average of the annual average concentrations for each of the modeled years.
[f] Maximum of the annual average concentrations across all modeled years.
[g] Maximum of the second-highest 24-hour average concentrations across all modeled years.
[h] Maximum of the 10-minute average concentrations across all modeled years.
[i] Maximum of the 15-minute average concentrations across all modeled years.
[j] Maximum of the highest 1-hour average concentrations across all modeled years.
[k] Maximum of the second-highest 1-hour average concentrations across all modeled years.
[l] Maximum of the highest 1-hour average concentrations across all modeled years.
[m] Maximum of the second-highest 1-hour average concentrations across all modeled years.
[n] First highest was used as the background concentration for 1-hour and 8-hour CO.
[o] Maximum of the 24-hour average concentrations across all modeled years.

The method used herein to consider existing background concentrations along with the results of modeling is based on the approach followed under the USEPA's New Source Review Prevention of Significant Deterioration (PSD) program. Under the PSD program, the USEPA establishes a screening level (referred to in the program as the Significant Impact Level or SIL) to determine whether a source's modeled ambient impact is "significant" such that it warrants what the USEPA refers to as a "cumulative air quality analysis" to demonstrate compliance with guidelines. Where a proposed source's modeled impact is deemed "insignificant or *de minimis*" using the SIL as a threshold for significance, the proponent is not required to model anything besides its own proposed emissions increase to show that the proposed source will not result in an exceedance of a guideline. If the source's modeled impact is found to be "significant" (i.e., exceeding a SIL), the proponent is required to complete a comprehensive, cumulative air quality impact analysis to demonstrate that the source's emissions will not cause or contribute to an exceedance of a guideline. The cumulative air quality impact analysis in this use includes modeling impacts of other sources to account for the cumulative air quality impacts that are predicted to occur, as well as potential inclusion of ambient monitoring data. This approach is based on the USEPA's position that when a proposed source's impact by itself is not considered "significant," any further effort on the part of the proponent to complete a cumulative source impact analysis involving other source impacts would only yield information of trivial or no value with respect to the required evaluation of the proposed source.

Consistent with the approach described above, a value equal to 10 percent of the applicable guideline for each averaging period was adopted as the screening criterion (i.e., the equivalent of the USEPA's "SIL"). The EIA already models from the outset both a Project-only and a "cumulative" case (involving modeling of Project emissions and other EEPGL project emission). Therefore, the screening criterion was used solely to determine whether existing background concentrations were added to the modeled concentrations for each scenario (i.e., Project-only and cumulative). Accordingly, for any pollutant with modeled impacts (not considering existing background concentrations) greater than 10 percent of an applicable guideline for an averaging period, this report provides the predicted concentration (without background) as well as the predicted concentration including background.

3.3 Predicted Concentrations and Comparison to Guidelines

Using the methodology described above, modeling was conducted with CALPUFF to predict maximum onshore ground-level concentrations of each pollutant as a result of emissions from Project sources. Model results were developed for each modeled pollutant, for each averaging period with an associated guideline concentration (Table 3-1). Additionally, the cumulative impact analysis modeling scenario combined the results from the Project with modeled emissions from the other EEPGL offshore activities identified above. Note that the "Modeled Case" emissions identified in Tables 23 and 2-4 were considered in both the Project only and cumulative modeling.

All results are summarized in Table 3-3 (Project-only) and Table 3-4 (Cumulative Scenario). For the Project-only modeling, maximum predicted concentrations (without background) at any potential onshore receptor location are no more than 6.3 percent of the applicable guideline for all pollutants and averaging periods.

For the cumulative scenario, maximum predicted concentrations (without background) at any potential onshore receptor location are no more than 28.4 percent of the applicable guideline for all pollutants and averaging periods.

Table 3-3: Summary of Modeling Results—Maximum Predicted Concentrations at Potential Onshore Receptor Locations (Project Only)

Pollutant	Averaging Period	Ranking	Guideline Concentration (µg/m³) [a]	Maximum Predicted Onshore Concentration (µg/m³) [b]			Percent of Guideline		
				2023–2024	2025–2027	2028–2044	2023–2024	2025–2027	2028–2044

µg/m³ = micrograms per cubic meter; CO = carbon monoxide; NA = not applicable; NO_2 = nitrogen dioxide; $PM_{2.5}$ = particulate matter (aerodynamic diameter less than 2.5 microns); PM_{10} = particulate matter (aerodynamic diameter less than 10 microns); SO_2 = sulfur dioxide

[a] WHO 2000; WHO 2005; WHO 2021; USEPA 2021

[b] Concentrations are the maximum predicted onshore concentrations across the modeled meteorological conditions.

[c] NOx to NO_2 conversion for model-predicted concentrations was based on the Tier 2 Ambient Ratio Method, which uses a 0.8 scaling factor for short-term averaging period and 0.75 for annual averaging.

All predicted concentration contributions for the Project-only scenario (Table 3-3) are less than 10 percent of the applicable guidelines. Accordingly, as per the methodology described above, background concentrations were not added to the predicted Project-only concentrations. For the cumulative scenario, predicted concentration contributions for the NO_2 1-hour (maximum), 24-hour (fourth highest), and annual (maximum) averaging periods exceeded 10 percent of the applicable guidelines. Accordingly, the maximum measured baseline concentrations from Table 3.2 for NO_2 (40.8 µg/m³ for the 1-hour averaging period, 24.07 µg/m³ for the 1-hour 98th percentile averaging period, 9.4 µg/m³ for the 24-hour averaging period, and 5.8 µg/m³ for the annual averaging period) were added to the predicted cumulative scenario concentrations, with the resulting total (with background) cumulative scenario concentrations summarized in Table 3-5.

Table 3-5: Summary of Modeling Results—Maximum Predicted Concentrations at Potential Onshore Receptor Locations (Cumulative Scenario) for NO_2 Including Background Concentrations

Pollutant	Averaging Period	Ranking	Guideline Concentration (µg/m³) [a]	Ambient Background Concentration (µg/m³)	Maximum Predicted Onshore Concentration (µg/m³) [b]			Percent of Guideline		
					2023–2024	2025–2027	2028–2044	2023–2024	2025–2027	2028–2044
NO_2 [c]	1-hour	Max	200	40.8	83.60	78.59	65.32	41.8%	39.3%	32.7%
	1-hour	98th Percentile	188	24.1	36.68	38.50	35.30	19.5%	20.5%	18.8%

Underwater Sound Assessment for Yellowtail Development Project; Offshore Guyana; Stabroek Block

Submitted to: Jason Willey, ERM.

Request: Asses the Applicability of the previously modelled underwater sound levels associated with the Liza Phases 1 and 2 and Payara Development Projects for the Yellowtail Development Project.

In December 2016, JASCO Applied Sciences (JASCO) carried out a modeling study for Esso Exploration and Production Guyana Limited (EEPGL) to predict underwater sound levels associated with the Liza Phase 1 Development Project located within the Stabroek Block (Matthews et al. 2016). This analysis was also applied to the Liza Phase 2 Development Project in 2018, due to the two projects being virtually identical at adjacent sites and with very similar environmental conditions. The recently proposed Yellowtail development project will be a new sound source in the region, centered about the FPSO 30 km ESE of the Liza Phase 1 FPSO. Seabed infrastructure will be installed at depths between 1,690 and 1,910 m, with pilling occurring between 1,690 and 1,780 m (Figure 1).

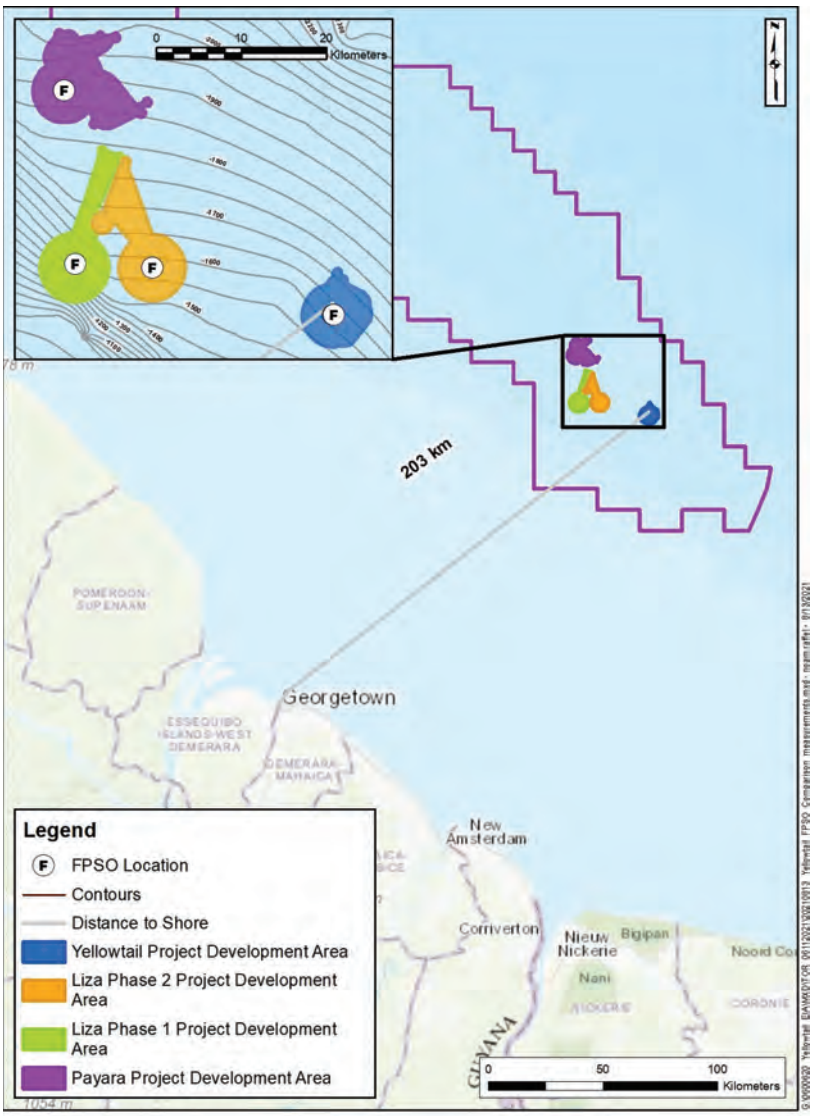

Figure 1. Locations of EEPGL sites in the Starbroek Block.

The sound footprints for the Liza Phase 1 scenarios were modeled to estimate distances to sound level threshold criteria for marine mammals based on:

- Injury, as defined by Southall et al. (2007), Wood et al. (2012), and Finneran (2015). These sound footprints were calculated as frequency-weighted (M-weighted) sound exposure levels (SEL) for 24 hours of operation.
- Behavioral disturbance, as defined by the U.S. National Marine Fisheries Service (HESS 1999, NMFS 2013). These sound footprints were calculated as unweighted sound pressure level (SPL) thresholds of 120 dB re 1 µPa (nonimpulsive sources) and 160 dB re 1 µPa (impulsive sources).

We assume that the same criteria would be used for the Yellowtail project to assess the effects on marine mammals.

EEPGL advised JASCO that the planned Yellowtail infrastructure and work activities would be comparable to those previously modelled for Liza phase 1. As such, we assume the source levels and scenarios would remain applicable for the Yellowtail development.

In 2016, we modeled sound propagation with JASCO's Marine Operations Noise Model (MONM) and JASCO's Full Waveform Range-dependent Acoustic Model (FWRAM). These models produce depth-, range- and azimuth-dependent sound fields associated with environmental parameters (including bathymetry, geoacoustic properties, and underwater sound speed profiles) that are specific to the Stabroek Block area. At the time, no site-specific information was available for developing geoacoustic properties or sound speed profiles. Thus, generic profiles for the modeled region were developed based on publicly available data (Rucker 1967, Hamilton 1980, Teague et al. 1990, Carnes 2009, Maxon Consulting Inc. 2014). These profile estimates provided conservative sound propagation results within the modeled area, which extended up to 100 km from the Liza Phase 1 FPSO vessel. No updated geoacoustic information is available.

As the original modelling for Liza Phase 1 occurred five years ago, more recent water-column sound speed profiles are now available to quantify the environment, but they do not affect the conclusions from the previous modeling. Sound speed profiles were extracted from the Global Ice Ocean Prediction System (GIOPS ECCC) for 2020 (Figure *2*) for the Yellowtail development region. These compare favorably to the profiles employed during the original modelling from 2016 for the Liza Phase 1 and 2 locations, Payara, and in the deep ocean off the continental shelf (Figure *3*). The differences in the sound speed profiles for the new data vs the older data were distributed about zero m/s and thus unlikely to affect overall sound propagation as the refraction of sound is determined by the shape of the profile which remains the same. The seabed development and operations at the Yellowtail project will be slightly deeper than the Liza P1 development. However, as the main source of sound for the pile driving operations is near the seabed, the similarity in sound speed profile at the seabed re-enforces our conclusion that the profiles are sufficiently equivalent, and that no new modelling is required.

Therefore, based on the bathymetric relationship between the Liza Phase 1 and Yellowtail sound source locations, the homogeneous environmental properties over a large area that encompasses both the Liza and Yellowtail projects development areas, and the similarity in noise-producing activities for the two projects, we estimate that model results for the Yellowtail scenarios would present little changes in the distances to marine mammal injury thresholds provided for Liza Phase 1. Indeed, due to the deeper waters at Yellowtail, sounds emitted there will attenuate spherically for greater distances than in shallower waters so that the effects distances are likely to be shorter than at Liza Phase 1. A new assessment of effects distances would be recommended if updated criteria to assess the effect on marine life are used (e.g. the guidance for US water contained in NMFS (2018)), new (more site-specific) geoacoustic information is available, or the nature of the Yellowtail operations differ from Liza Phase 1.

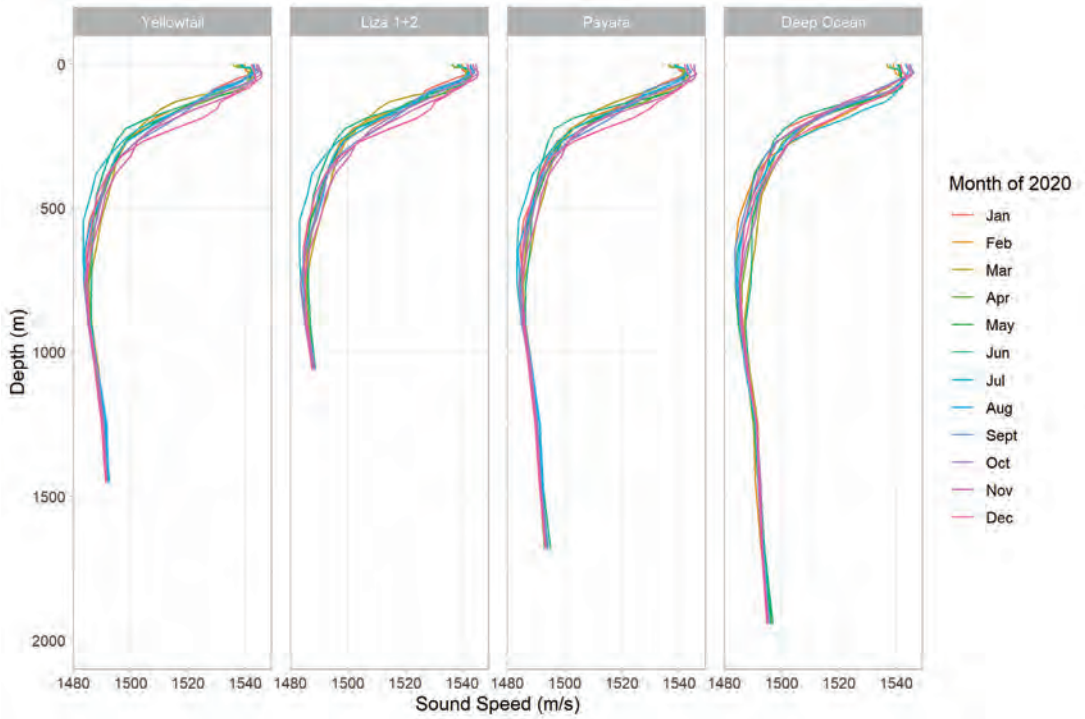

Figure 2. Modelled local and regional sound speed profiles (from GIOPS) used in the similarity assessment for the proposed yellowtail development from 2020.

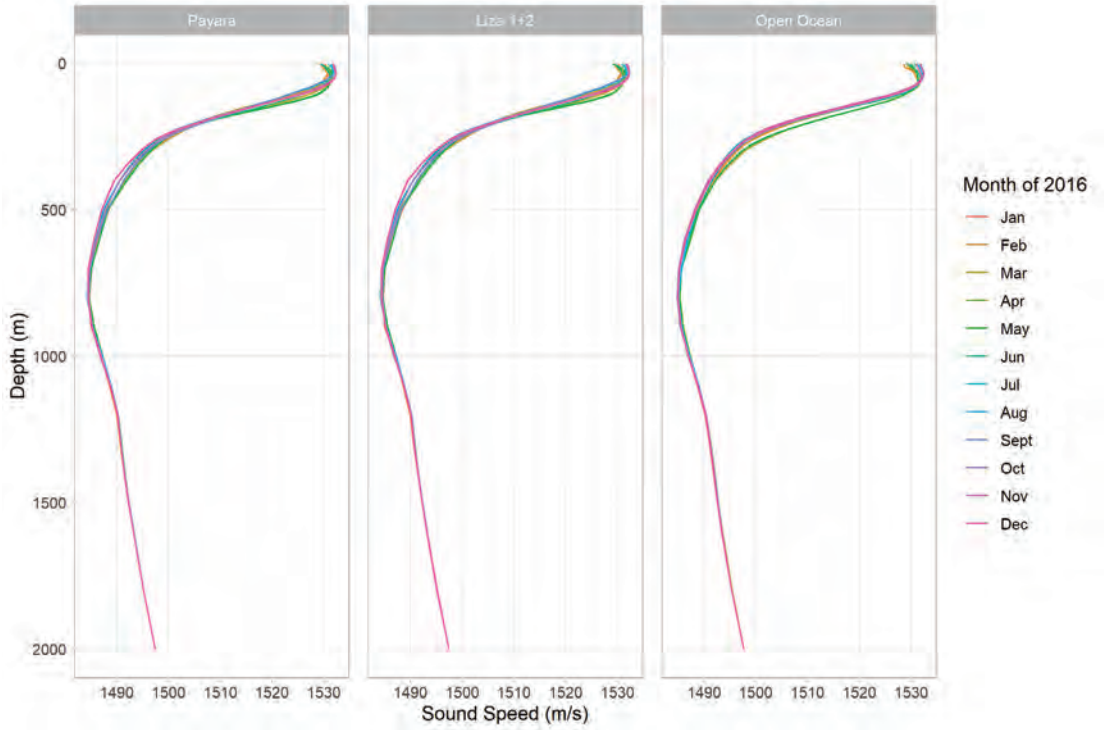

Figure 3. Local and regional sound speed profiles used in the original acoustic modelling impact assessment for the Liza phase 1 development in 2016.

Executive Summary

This underwater sound modeling study predicts underwater sound levels associated with the Liza Phase 1 Development Project (hereinafter referred to as the Project). The Project is designed to develop and produce oil in the ExxonMobil Liza field, located within the Stabroek Block, approximately 190 km offshore central Guyana. The modeled Project activities include drilling development wells, installing and operating a Floating Production Storage and Offloading (FPSO) vessel, and installing Subsea, Umbilical, Riser, and Flowline (SURF) equipment. Sound footprints from representative sound sources, including vessels, a vertical seismic profile (VSP) source, and underwater impact pile driving equipment, were considered. The model results were used to estimate distances to marine mammal injury thresholds, based on best available science.

The underwater sound fields were modeled for water column sound speed profiles representative of April. This time corresponds with lowest surface temperatures, which lead to upward sound refraction and longer-distance sound propagation. The obtained results therefore ensure cautionary estimates of the distances to received sound level thresholds.

Six scenarios were modeled to simulate the following:

1. The operation of a Floating Production Storage and Offloading (FPSO) vessel,
2. The installation of the FPSO vessel, which includes the associated installation and support vessels,
3. The operation of a drill ship and a pipelaying vessel at one of the two drill centers, approximately 13 km north of the FPSO,
4. The operation of a VSP source in the vicinity of the drill centers,
5. Underwater impact pile driving of SURF equipment piles at one of the two drill centers, approximately 13 km north of the FPSO, and
6. Underwater impact pile driving of anchor mooring piles at the FPSO location.

The models produced estimates of the sound fields in M-weighted SEL_{24h} and peak sound pressure levels (PK). The sound fields account for source-specific sound emission characteristics (Section 4.1) and site-specific environmental parameters (Section 4.2). The estimated sound fields are applicable to other locations within the Project area, where site-specific environmental parameters are similar.

For scenarios 1 through 3, the distances to injury thresholds from vessels are small (<10 m). Distances to low- and mid-frequency cetacean injury thresholds for the VSP source were estimated for three sets of acoustic effects criteria. The distances vary from ≤35 m for mid-frequency cetaceans to ≤143 m for low-frequency cetaceans. Distances to the same thresholds for underwater impact pile driving operations are the longer than for the other scenarios. The distances vary from 100 to 762 m for mid-frequency cetaceans and from 1,025 to 1,375 m for low-frequency cetaceans. The sound levels at or above injury thresholds for impact pile driving were found close to the ocean bottom, at depths >1,000 m.

1. Introduction

JASCO Applied Sciences (JASCO) carried out a modeling study for Esso Exploration and Production Guyana Limited (EEPGL) to predict underwater sound levels associated with the Liza Phase 1 Development Project (hereinafter referred to as the Project) located within the Stabroek Block, approximately 190 km offshore central Guyana (Figure 1). The Project activities include installing and operating a Floating Production, Storage, and Offloading (FPSO) vessel, installing and operating Subsea Umbilical, Riser, and Flowline (SURF) equipment, as well as associated development drilling at two drill centers in the Liza field. Each drill center consists of an underwater injection (I) and a production (P) component, tied to the FPSO by the SURF equipment. Installing this Project infrastructure will require the use of multiple vessels, including drill ships, pipelaying vessels, tugs, barges, support, and supply vessels of various sizes. During production operations, the FPSO will be moored. Hydrocarbons produced from the wells will be offloaded onto tankers. This offloading operation may also require the use of tugs, while supply vessels will regularly dock alongside the FPSO.

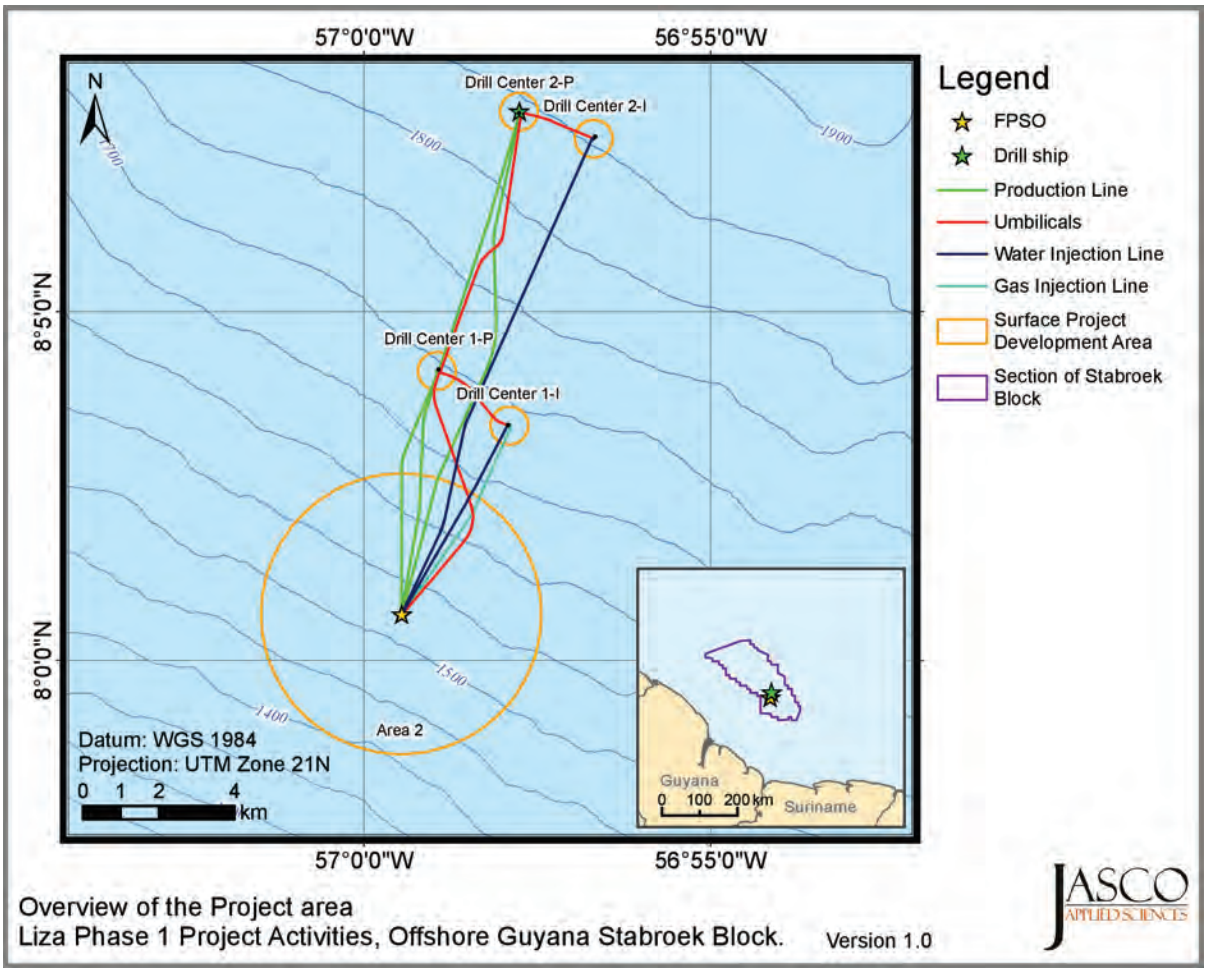

Figure 1. Overview of the Guyana Stabroek project area.

Six scenarios were considered in this modeling study, which include:

1. The operation of an FPSO vessel,
2. The installation of the FPSO vessel, which includes mooring the FPSO, and using several installation and service vessels, and
3. The installation of subsea flowlines and risers and operation of Drill Center 2-P, approximately 13 km north of the FPSO, which includes the operation of a drill ship, a pipelaying vessel, and multiple service vessels,
4. The operation of a VSP source in the vicinity of Drill Centers 2-P and 2-I,
5. The installation of piles for SURF equipment at Drill Center 2-P through underwater impact pile driving, and
6. The installation of anchor mooring piles at the FPSO location through underwater impact pile driving.

The specific vessels, the characteristics of the VSP source, as well as the specifications of the piles and driving hammer are at present unknown. Measurements from surrogate vessels, including the FPSO, drill ship, pipelaying vessel, tugs, and support vessels, were used to derive the acoustic characteristics of the vessels that will likely be used in the operations. The VSP source considered here is a six-element air gun array with a total volume of 1200 in^3. The source pressure signature of this array was modeled with JASCO's Airgun Array Source Model (AASM). This model accounts for individual element volume and position within the array. All modeled piles were 25 m in length, and 5 m in diameter. The modeled impact hammer model is the MENCK 500T, with underwater settings. It was assumed that it will take 5 hours to drive each pile, and that one pile will be driven per 24 hour period. The forcing function transferred from the hammer to the pile was modeled using the GRLWEAP model (GRLWEAP, Pile Dynamics 2010); the sound signature along the pile was modeled using JASCO's pile vibration and near-field sound radiation model (MacGillivray 2014).

Sound propagation was modeled with JASCO's Marine Operations Noise Model (MONM) and JASCO's Full Waveform Range-dependent Acoustic Model (FWRAM). These models produced depth, range, and azimuth dependent sound fields associated with environmental parameters, including bathymetry, that are specific to the Stabroek Block area.

The sound footprint for each scenario was modeled to estimate distances to sound level thresholds based on injurious criteria prescribed by Southall et al. (2007) and Finneran (2015). The sound footprints were calculated as frequency-weighted (M-weighted) sound exposure levels (SEL) for 24 hours of operation.

Section 2 describes the acoustic effect criteria for this study. Definitions of the different metrics associated with the criteria are provided in Appendix A.1. Section 3 discusses the methodology for predicting the source levels and modeling the sound propagation. Section 4 describes the various input parameters pertinent to this study. Section 5 presents the results in two formats: tables of maximum and 95% distances to sound level thresholds and a sound field contour map showing the directivity of the various sound level threshold contours for the VSP source and impact pile driving operations. Section 6 presents an analysis of the results.

1.1. Modeled Scenarios

Various vessels were involved in the first three scenarios, including tugs, supply vessels, and support vessels. At the time of this study, the exact location and description of each vessel were unknown. The modeled scenarios represent an estimate of the general location of each vessel for a 24 hour period; the surrogate vessels provide estimates of the sound emission levels for the proposed vessel fleet. Table 1 and Figures 2–4 list the vessels, their operational state, and their location. Scenario 4 involves a VSP source operating near Drill Center 2-P (Table 1; Figure 4). Scenarios 5 and 6 represent the installation of SURF equipment and FPSO anchor mooring piles using an underwater impact pile driver (Table 1; Figure 5).

Table 1. List of vessels for each modeled scenario. FPSO: Floating Production Storage and Offloading; VSP: Vertical Seismic Profile.

Scenario	Vessel/Source type	Operational state	Location		UTM Coordinates

2. Acoustic Effects Criteria

Underwater sound can affect marine fauna in various ways. The question of which acoustic exposure levels might cause injury to marine mammals is still an active research. Since 2007, several expert groups have investigated SEL and peak pressure-based assessment approaches for injury using methods similar to those applied for humans, and a few key papers have been published on the topic. Those publications are reviewed, and the relative criteria discussed, in Appendix A.2. In the present section we propose specific thresholds used in other recent studies that are the most likely candidates for more widespread use; we caution readers, however, that assessment criteria are likely to evolve in the near future as research is progressing rapidly in this field.

Results of this modeling study are presented in terms M-weighted sound exposure level (SEL; $L_{E,24h}$) and peak pressure level (PK; L_{pk}) thresholds for injury to low- and mid-frequency cetaceans, based on two sets of criteria (Table 2): Southall et al. (2007) and Finneran (2015). These criteria have been chosen to include standard thresholds and thresholds suggested by the best available science, as reviewed and discussed in Appendix A.2. Low-frequency cetaceans, including baleen whales, and mid-frequency cetaceans, including dolphins and small whales, have been observed within or near the Project area. This study therefore focuses only on these marine mammal hearing groups.

Table 2. Marine mammal injury (Permanent Threshold Shift (PTS) onset) thresholds based on Southall et al. (2007), and Finneran (2015). PK and SPL in dB re 1 µPa; weighted SEL (24 hours) in dB re 1 µPa²·s.

Hearing group	Impulsive source				Non-impulsive source

	PK	Weighted SEL_{24h}	PK	Weighted SEL_{24h}	PK	Weighted SEL_{24h}	Weighted SEL_{24h}
Low-frequency cetaceans	230	198	230	192	230	215	207
Mid-frequency cetaceans	230	198	230	187	230	215	199

3. Methods

Underwater acoustic field for the studied vessels were modeled using JASCO's Marine Operations Noise Model (MONM), which is based on source levels derived from measurements of surrogate vessels.

Three complementary acoustic models were used to predict the underwater acoustic field for the studied seismic source. The pressure signatures and directional source levels of the VSP source were predicted with JASCO's Air gun Array Source Model (AASM). The acoustic fields around the array, in terms of M-weighted SEL_{24h}, were modeled with MONM. JASCO's Full Waveform Range-dependent Acoustic Model (FWRAM) was used to determine peak pressure levels as a function of azimuth, depth, and range from the array.

The acoustic source signature for impact pile driving operations was modeled using JASCO's physical model of pile vibration and near-field sound radiation (MacGillivray 2014), in conjunction with the GRLWEAP 2010 wave equation model (GRLWEAP, Pile Dynamics 2010). The acoustic fields, in terms of M-weighted SEL_{24h} and peak pressure levels, were modeled with JASCO's FWRAM.

M-weighting was applied for two hearing groups to weight the importance of received sound levels according to their constituent frequencies.

3.1. Modeling Acoustic Source Levels

3.1.1. Vessels

Several types of vessels were modeled in this study, including an FPSO, a drill ship, a pipelaying vessel, tugs, barges, supply vessels, and support vessels. The vessels characteristics are presented in Section 4.1.1. Underwater sound that radiates from vessels is produced mainly by propeller and thruster cavitation (Ross 1976, §8.6), with a small fraction produced by sound transmitted through the hull, such as sound from engines, gearing, and other mechanical systems (Spence et al. 2007). Sound levels thus tend to be the highest when propulsion systems are used at high power. For example, during dynamic positioning in high currents or winds, or transiting at high speeds. A vessel's sound signature depends on the vessel's size, power output, and propulsion system characteristics (e.g., blade shape and size). Vessels produce broadband acoustic energy with most of the energy emitted below a few kilohertz. Sound from onboard machinery, particularly sound below 200 Hz, dominates the sound spectrum before cavitation begins—normally around 8 to 12 knots on many commercial vessels (Spence et al. 2007).

At the time of this study, the specific vessels engaged in installing and operating at the drill centers were unknown. Generalized source spectra were computed by comparing the expected specifications of the vessels to that of surrogate vessels for which source levels were available. Source levels for the surrogate were derived from measured received levels during various operational states. To account for the differences between the specification of the modeled and surrogate vessels, the spectra of the surrogates were corrected by the power ratings of the modeled and reference vessels:

$$S(f,P) = S_0(f) + 10\log\left(\frac{P}{P_0}\right) \quad (1)$$

where S_0 is the reference spectrum and P_0 is the reference power rating (Ross 1976, §8.6). When needed, surrogate spectra were extrapolated using −2 dB per decade at frequencies below 100 Hz and −1 dB per decade at frequencies above 1000 Hz (Ross 1976, §8.6).

3.1.2. Vertical Seismic Profile Source

The VSP source considered here is a six-element air gun array with a 1200 in^3 total volume. The source characteristics are presented in Section 4.1.2. The source levels and directivity of the VSP array were predicted with JASCO's Air gun Array Source Model (AASM; MacGillivray 2006a). This model is based on the physics of oscillation and radiation of air gun bubbles described by Ziolkowski (1970). The model solves the set of parallel differential equations that govern bubble oscillations. AASM also accounts for nonlinear pressure interactions between air guns, port throttling, bubble damping, and generator-injector (GI) gun behavior that are discussed by Dragoset (1984), Laws et al. (1990), and Landro (1992). AASM includes four empirical parameters that were tuned so model output matches observed air gun behavior. The model parameters fit to a large library of empirical data using a "simulated annealing" global optimization algorithm. These data are measurements of the signatures of Bolt 600/B guns ranging in volume from 5 to 185 in^3 (Racca and Scrimger 1986).

While air gun signatures are highly repeatable at low frequencies, which are used for seismic imaging, at higher frequencies their sound emissions have a large random component that cannot be predicted using a deterministic model. Therefore, AASM uses a stochastic simulation to predict the high-frequency (560−25,000 Hz) sound emissions of individual air guns, using a data-driven multiple-regression model. The multiple-regression model is based on a statistical analysis of a large collection of high quality seismic source signature data recently obtained from the Joint Industry Program (JIP) on Sound and Marine Life (Mattsson and Jenkerson 2008). The stochastic model uses a Monte-Carlo simulation to simulate the random component of the high-frequency spectrum of each element in an array. The mean high-frequency spectra from the stochastic model augment the low-frequency signatures from the physical model, allowing AASM to predict source levels at frequencies up to 25,000 Hz.

AASM produces a set of "notional" signatures for each array element based on:

- Array layout
- Volume, tow depth, and firing pressure of each air gun
- Interactions between different elements in the array

These notional signatures are the pressure waveforms of the individual elements at a standard reference distance of 1 m; they account for the interactions with the other elements in the array. The signatures are summed with the appropriate phase delays to obtain the far-field source signature of the entire array in all directions. This far-field array signature is filtered into 1/3-octave-bands to compute the source levels of the array as a function of frequency band and azimuthal angle in the horizontal plane (at the source depth), after which it is considered to be a directional point source in the far field.

A seismic array consists of many sources and the point-source assumption is invalid in the near field where the array elements add incoherently. The maximum extent of the near field of an array (R_{nf}) is:

$$R_{nf} < \frac{l^2}{4\lambda} \tag{1}$$

where λ is the sound wavelength and l is the longest dimension of the array (Lurton 2002, §5.2.4). For example, an array length of l = 2 m yields a near-field range of 1.5 m at 2 kHz. Beyond this R_{nf} range, the array is assumed to radiate like a directional point source and is treated as such for propagation modeling.

The interactions between individual elements of the array create directionality in the overall acoustic emission. Generally, this directionality is prominent mainly at frequencies in the mid-range between tens of hertz to several hundred hertz. At lower frequencies, with acoustic wavelengths much larger than the separation distances between array elements, the directionality is small. At higher frequencies, the pattern of lobes is too finely spaced to be resolved and the effective directivity is less.

3.1.3. Impact Pile Driving

A physical model of pile vibration and near-field sound radiation is used to calculate source levels of piles. The physical model employed in this study computes the underwater vibration and sound radiation of a pile by solving the theoretical equations of motion for axial and radial vibrations of a cylindrical shell. These equations of motion are solved subject to boundary conditions, which describe the forcing function of the hammer at the top of the pile and the soil resistance at the base of the pile (Figure 6). Damping of the pile vibration due to radiation loading is computed for Mach waves emanating from the pile wall. The equations of motion are discretised using the finite difference (FD) method and are solved on a discrete time and depth mesh.

In order to model the sound emissions of the piles, it was also necessary to model the force of the pile driving hammers. The force at the top of the pile was computed using the GRLWEAP 2010 wave equation model (GRLWEAP, Pile Dynamics 2010), which includes a large database of simulated hammers—both impact and vibratory—based on the manufacturer's specifications. The forcing functions from GRLWEAP were used as inputs to the FD model to compute the resulting pile vibrations.

The sound radiating from the pile itself is simulated using a vertical array of discrete point sources. The point sources are centered on the pile axis. Their amplitudes are derived using an inverse technique, such that their collective particle velocity—calculated using a near-field wave-number integration model—matches the particle velocity in the water at the pile wall. The sound field propagating away from the vertical source array is then calculated using a time-domain acoustic propagation model (e.g., FWRAM; Appendix A.5.3). MacGillivray (2014) describes the theory behind the physical model in more detail.

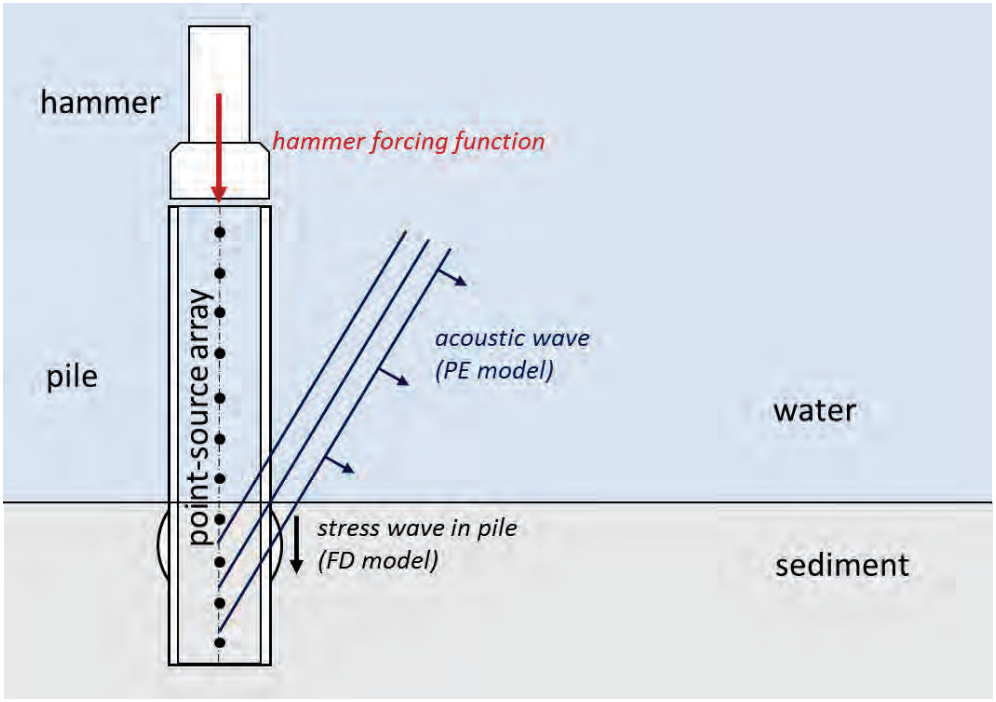

Figure 6. Physical model geometry for impact driving of a cylindrical pile (vertical cross-section). The hammer forcing function is used with the finite difference (FD) model to compute the stress wave vibration in the pile. A vertical array of point sources is used with the parabolic equation (PE) model to compute the acoustic waves that the pile wall radiates.

3.2. Modeling Sound Propagation

Underwater sound propagation (i.e., transmission loss) for the vessels and the VSP source exposure levels was predicted with JASCO's MONM (see Appendix A.5.2). The model computes received SEL (per-pulse SEL for impulsive sources) for directional sources located at a specified depth. It incorporates site-specific environmental properties including a bathymetric grid of the modeled area, in-water sound speed as a function of depth, and a geoacoustic profile based on the overall stratified composition of the seafloor. The model computes acoustic fields in three dimensions by modeling transmission loss within two-dimensional (2-D) vertical planes aligned along radials covering a 360° swath from the source.

MONM treats frequency dependence by computing acoustic transmission loss at the center frequencies of 1/3-octave-bands. Sufficiently many 1/3-octave-bands, from 10 Hz to 32 kHz, are modeled to include the majority of acoustic energy emitted by the source. Sound propagation at frequencies from 5 to 32 kHz was modeled by modifying the transmission loss at 5 kHz with the frequency- and range-dependent absorption coefficient for sea water (François and Garrison 1982a). Although mostly insignificant at lower frequencies, absorption coefficients were also applied from 10 Hz to 5 kHz for consistency. The broadband underwater sound field, expressed in terms of M-weighted per-pulse SEL, was computed by filtering and summing the received 1/3-octave-band levels.

JASCO's FWRAM (see Appendix A.5.3) was used to determine peak pressure levels from the VSP source and per-pulse SEL from pile driving operations. FWRAM uses the same computational algorithm as MONM, but computes pressure waveforms via Fourier synthesis of the modeled acoustic transfer function in closely spaced frequency bands. FWRAM employs the array starter method to accurately model sound propagation from a spatially distributed source such as an underwater pile (MacGillivray and Chapman 2012).

The parabolic equation (PE) approximation used in FWRAM (Appendix A.5.3) is valid for sound propagating within a vertical angle range of at least 45° above and below the horizontal plane at the source depth (the exact angle depends on the environment). In the case of underwater impact pile driving, where the pile extends only over a fraction of the water column, the received levels above the pile (propagating at a >45° angle from the horizontal plane) may be underestimated using this model. The main acoustic waves around the pile propagate, however, at an angle of ~17° from the horizontal plane (Reinhall and Dahl 2011). FWRAM therefore provides a valid estimate of the distances to injury thresholds, which occur well within the PE approximation angle.

This approach, combined with the pile driving source model, accurately estimates spectral levels within the 10–800 Hz band where most of the energy from impact pile driving is concentrated. An extrapolation method (Zykov et al. 2016) was used to extend the modeled levels in 1/3-octave-bands up to 25 kHz, by applying a −2 dB per 1/3-octave-band roll-off coefficient to the per-pulse SEL value starting at the 800 Hz band. The acoustic energy levels at these higher frequencies are required to correctly assess the acoustic fields against Finneran (2015) criteria. The broadband underwater sound field, expressed in terms of M-weighted per-pulse SEL, was computed by filtering and summing the received 1/3-octave-band levels.

The injury thresholds evaluated here account for the total acoustic energy a marine mammal is subjected to within a defined period (24 hours in the present case). In the present study, the M-weighted SEL_{24h} were obtained by assuming a stationary scenario. With this simplified approach the acoustic energy (SEL) for 1 sec (for non-impulsive sources) or a single pulse (for impulsive sources) at a particular location was replicated in situ to estimate the cumulative metric. For a given number (N) of source activity seconds or of acoustic pulse events over a 24-hour period, SEL_{24h} was thus computed using the basic formula:

$$SEL_{24h} = SEL + 10\log_{10}(N) \ . \qquad (2)$$

By assuming stationary sources, the method provides conservative estimates of the maximum extent of each sound level isopleth. This approach also yields notional values that are not strongly dependent on the environment or on the position of each source, which simplifies comparisons between different source types and acoustic effect criteria.

Although a more complex analysis would be outside the scope of this study, an important consideration that qualifies the cumulative received level estimates is that individuals of most species do not remain stationary throughout the exposure period. Their dose accumulation, therefore, depends on their movement and would likely be lower than for a stationary receiver. A second issue is that animals tend to recover from the sub-injurious effects of sound exposure over time; the paradigm of a strictly dosimetric accumulation is not therefore altogether correct, but the recovery period of most species is unknown.

3.3. Calculating Distances to Acoustic Effect Thresholds

The underwater sound fields predicted by the propagation models were sampled so that the received sound level at each location in the horizontal plane was taken to be the maximum value over all modeled depths for that location. Two distances from the source are reported for each sound level: 1) R_{max}, the maximum range at which the given sound level was encountered in the modeled maximum-over-depth sound field over all azimuths, and 2) $R_{95\%}$, the maximum range at which the given sound level was encountered after the 5% farthest such points were excluded (Figure 7). The $R_{95\%}$ is used because the maximum-over-depth sound field footprint is often non-circular and can include anomalous protrusions along a few azimuths. Regardless of the geometric shape of the maximum-over-depth footprint, $R_{95\%}$ is the predicted range encompassing at least 95% of the area (in the horizontal plane) that would be exposed to sound at or above that level. The difference between R_{max} and $R_{95\%}$ depends on the source directivity and the heterogeneity of the acoustic environment. The $R_{95\%}$ excludes ends of protruding areas or small isolated acoustic foci not representative of the nominal ensonification zone.

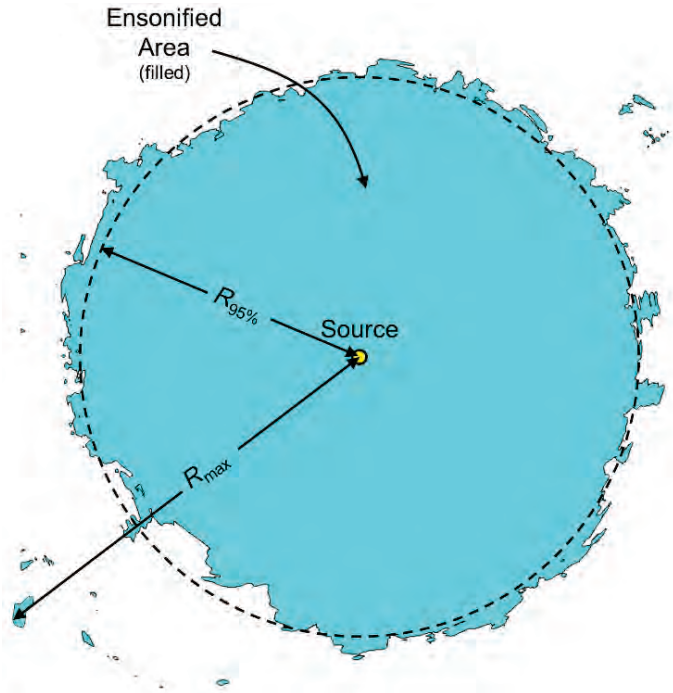

Figure 7. Example of an area ensonified to an arbitrary sound level showing R_{max} and $R_{95\%}$ radii.

4. Model Parameters

4.1. Acoustic Source Parameters

4.1.1. Vessels

A surrogate source vessel was chosen to represent each of the proposed vessels modeled in this study (Table 3). For vessels where the surrogate was significantly different in length, width, draft, or power, the surrogate's spectrum was adjusted based on the ratio of available power between the proposed and surrogate vessel (Section 3.1.1).

In Scenario 1 (Table 1; Figure 2), three tugs held the tanker in position (i.e., the tanker's main engine and propulsion system were idling or off). Thus, the sound levels from the tanker were neglected in the modeled scenario because they will be significantly lower (by at least 10 dB) than sounds from the tugs.

In Scenario 2 (Table 1; Figure 3), sound levels from the fast supply vessel, a small craft approximately 19 m long with a draft of less than 1 m, were also expected to be significantly lower (~150 dB re 1 µPa @ 1 m; Funk et al. 2008 §3.7) than sound levels from the adjacent vessels. This vessel was excluded from the modeled scenario.

The specific characteristics of the Floating Production Storage and Offloading (FPSO) that will be used in this project are unknown at present. The spectra used in Scenarios 1 and 2 were derived from the recordings of six FPSOs during various operational stages (Erbe et al. 2013). In Scenario 1, the FPSO was expected to be moored and operating; its spectrum was modeled using the 5th percentile 1/3-octave-band spectrum derived from all the FPSO source spectra recorded. In Scenario 2, tugs positioned the FPSO during installation and mooring. Such operations were expected to be noisier than in Scenario 1; the FPSO spectrum was modeled using the 95th percentile 1/3-octave-band spectrum derived from all the source spectra recorded.

Since the tugs in each scenario will be engaged in various activities (e.g., transiting at various speed, pulling and pushing vessels, handling cables and anchors), the spectra of the surrogate tug, recorded during transit at half and full speed and during anchor pulling, were averaged to produce a mean 1/3-octave-band spectrum.

The source depth for vessels other than the drill ship was based on the depth at which cavitation from the propulsion system was expected to occur. Gray and Greenley (1980) estimate that the center of the cavitation volume occurs below the propeller blade arc, by an amount equal to ~15% of the propeller diameter. The modeled source depth was estimated by:

$$Z_s = D - 0.85 \times \phi_{prop} \tag{3}$$

where Z_s is the source depth, D is the depth at the bottom of the propeller (often equal to the draft) of the proposed vessel, and $\varnothing_{\text{prop}}$ is the diameter of its propeller.

During drilling operations, sound will be generated at many locations along the drill shaft. For the purpose of this study, the sound was assumed to be concentrated at the top of the drill shaft; the source depth was equal to the operational draft of the drill ship (12 m).

Table 3. Specifications of proposed and surrogate vessels used to estimate source levels.

4.1.2. Vertical Seismic Profile Source

The Schlumberger High-performance Magnum six-gun array (1200 in³ total volume) was modeled as a surrogate VSP source in Scenario 4. The array consists of two vertically-triangular air gun clusters with in-line separations of 2 m. The first cluster has three 150 in³ elements with 0.9 m separation, the second cluster has three 250 in³ elements with a 1.1 m separation. In both clusters, the center air gun is shallower. The elements are fired simultaneously at 2000 psi air pressure. The array was modeled at a 4.5 m depth (the center of the clusters). It is estimated that the VSP source will produce 20–40 pulses within 6–12 hours of operation. Figure 8 illustrates the element distribution in the horizontal (*x*-*y*) plane, and Table 4 shows the array specifications.

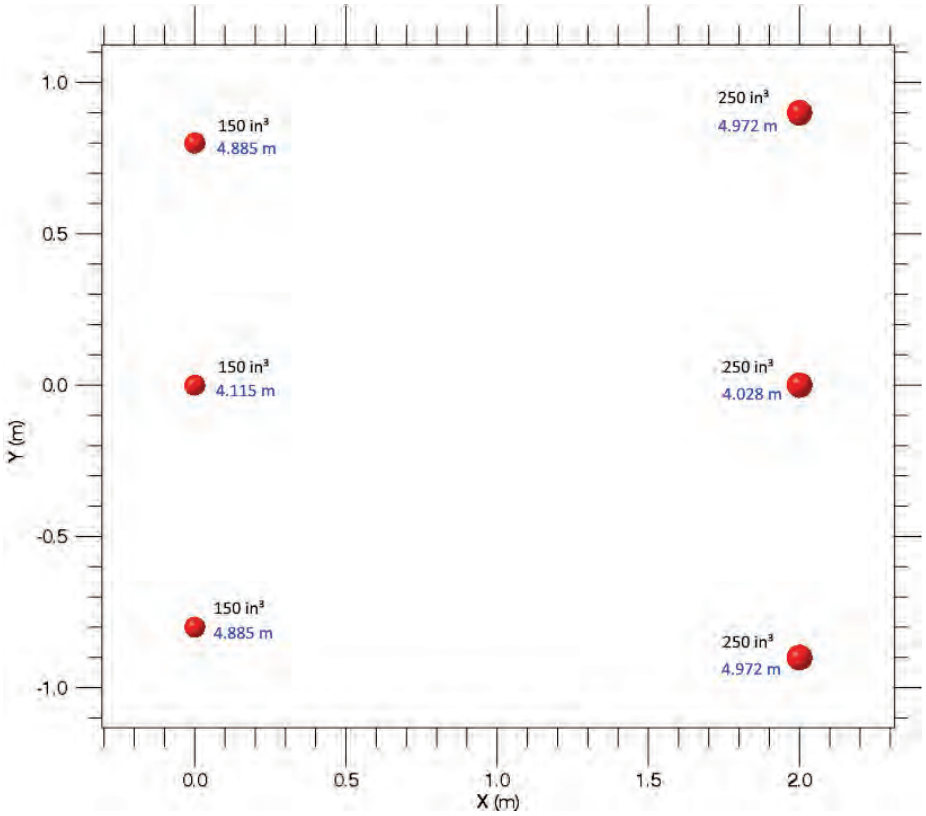

Figure 8. Layout of the High-performance Magnum six-gun array (1200 in³ total volume, 4.5 m depth), composed of 6 elements. Black labels indicate element volume in cubic inches; blue labels indicate the depth of the element relative to the sea surface.

Table 4. Relative positions of the elements within the 1200 in^3 array.

Element	*x* (m)	*y* (m)	*z* (m)	Volume (in^3)
1	0.0	0.000	4.115	150
2	0.0	−0.445	4.885	150
3	0.0	0.445	4.885	150
4	−2.0	0.000	4.028	250
5	−2.0	−0.545	4.972	250
6	−2.0	−0.545	4.972	250

4.1.3. Impact Pile Driving

Impact pile driving of cylindrical steel piles was modeled at two locations (Scenarios 5 and 6; Table 1). At both locations, the water depth was much deeper (1524.4 m and 1842.7 m) than the length of the pile (25 m long; 5 m in diameter). The MENCK 500T underwater hammer was used as the impact pile driver. A generic pile helmet, with a weight 1/5 that of the hammer (Parola 1970), was assumed with the default parameters of the hammer in the GRLWEAP 2010 wave equation model.

Information on the penetration rate per blow was unknown at the time of this study. The maximum number of strikes per minute (38) for the modeled hammer was assumed over a driving period of 5 hours. One driving period was assumed to occur every 24 hours.

4.2. Environmental Parameters

4.2.1. Bathymetry

Bathymetry data, covering an area of approximately 23 × 21 km centered on the modeled sites, was provided by EEPGL. For the long-range modeling (up to 100 km from the FPSO and the drill ship), this grid was extended using data from SRTM15+ (v1.0; Becker et al. 2009, Sandwell et al. 2014) global bathymetry grid, with a resolution of 30 arc-seconds (~460 × 460 m at the studied latitude), to produce a 150 × 150 km region. The data were re-gridded, by minimum curvature gridding, onto a Universal Transverse Mercator (UTM) Zone 21 coordinate projection with a regular grid spacing of 100 × 100 m.

4.2.2. Geoacoustics

The geoacoustic properties of surficial seabed layers depend on the sediment type. As the porosity decreases, the compressional sound speed, sediment bulk density, and compressional attenuation increase. For each modeled location, MONM assumes a single geoacoustic profile of the seafloor for the entire modeled area. The acoustic properties required by MONM are:

- Sediment bulk density,
- Compressional-wave (or P-wave) speed,
- P-wave attenuation in decibels per wavelength,
- Shear-wave (or S-wave) speed, and
- S-wave attenuation, also in decibels per wavelength.

Along the Guyana coast, suspended Amazonian sediments and fluvial mud from various Guyana rivers are transported eastward with the Guiana Current. This large volume of sediment deposition results in a thick (estimated up to 30 m; Rucker 1967) and fairly uniform layer of fine-grained sediment (Maxon

Consulting Inc. 2014). This surficial sediment layer, also characterized by a low concentration of organic carbon (Maxon Consulting Inc. 2014), overlays a mixture of sand and clay ~30–100 m thick (Rucker 1967).

The estimated geoacoustic profile (Table 5) was based on empirical formulas presented by Hamilton (1980). Without information from recent boreholes, a generic geoacoustic profile for silt-clay sediments was used with a 1.3 m/s per meters below the seafloor (mbsf) sound-speed gradient. The density and P-wave attenuation coefficients were taken from Hamilton (1980).

Table 5. Geoacoustic properties of the sub-bottom sediments as a function of depth, in meters below the seafloor (mbsf). Within each depth range, each parameter varies linearly within the stated range.

Depth (mbsf)	Material	Density (g/cm³)	P-wave speed (m/s)	P-wave attenuation **(dB/λ)**	S-wave speed (m/s)	S-wave attenuation **(dB/λ)**
0–30	Silt-clay	1.45–1.49	1500–1539	0.17–0.18	200	3.0
30–100	Sand-clay	1.83–2.00	1623–1700	1.21–2.00		
100–500	Sand-clay	2.00	1700–2100	2.00		
>500	Sand-clay	2.00	2100	2.00		

4.2.3. Ocean Sound Speed Profile

The ocean sound speed profiles for the modeled sites were derived from temperature and salinity profiles from the U.S. Naval Oceanographic Office's *Generalized Digital Environmental Model V 3.0* (GDEM; Teague et al. 1990, Carnes 2009). GDEM provides an ocean climatology of temperature and salinity for the world's oceans on a latitude-longitude grid with 0.25° resolution, with a temporal resolution of one month, based on global historical observations from the U.S. Navy's Master Oceanographic Observational Data Set (MOODS). The climatology profiles include 78 fixed depth points to a maximum depth of 6800 m (where the ocean is that deep). The GDEM temperature-salinity profiles were converted to sound speed profiles according to the equations of Coppens (1981):

$$\begin{aligned} c(z,T,S,\phi) &= 1449.05 + 45.7t - 5.21t^2 - 0.23t^3 \\ &\quad + \left(1.333 - 0.126t + 0.009t^2\right)(S-35) + \Delta \\ \Delta &= 16.3Z + 0.18Z^2, \quad Z = \frac{z}{1000}\left[1 - 0.0026\cos(2\phi)\right], \quad t = \frac{T}{10} \end{aligned} \tag{4}$$

where z is water depth (m), T is temperature (°C), S is salinity (psu), and ϕ is latitude (radians).

Mean monthly sound speed profiles were derived from the GDEM profiles at the FPSO and drill ship locations. There are no significant variations in sound speed with geographical location. Monthly variations in sound speed are also minimal, although the profile in April tends to be mostly upward refracting in the top 100 m (Figure 9). This month is therefore expected to promote longest range propagation and was used for all modeled scenarios.

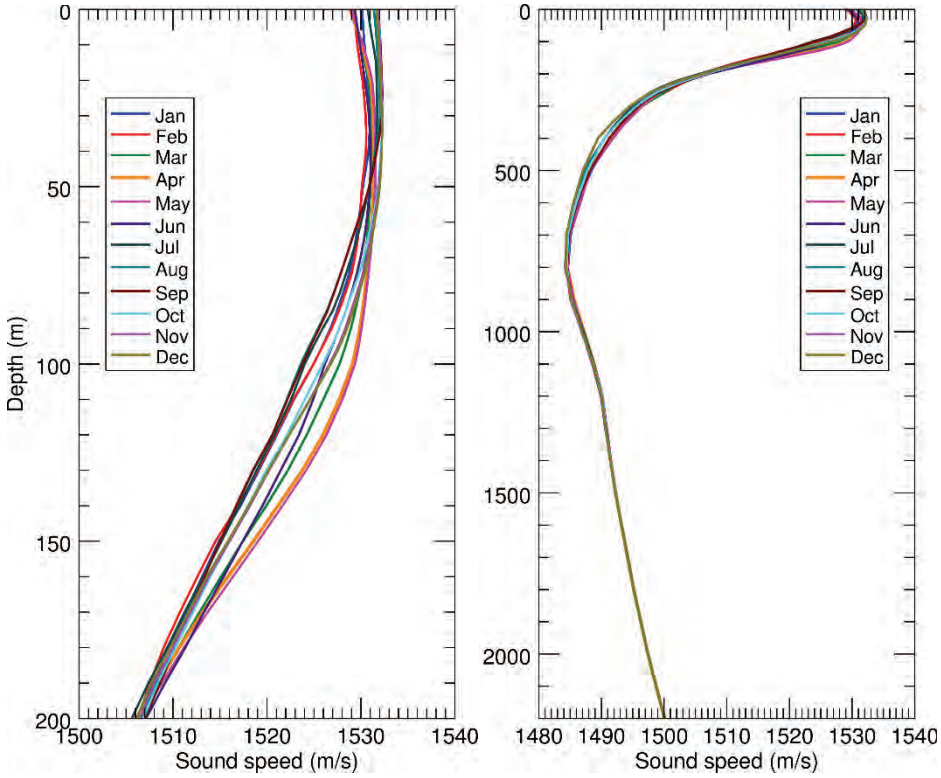

Figure 9. Mean monthly sound speed profiles (left: top 200 m; right: entire water column) at the FPSO location (08° 00' 39.53" N, 056° 59' 27.31" W) derived from data obtained from *GDEM V 3.0* (Teague et al. 1990, Carnes 2009).

4.3. Sound Propagation Modeling Zones

For the purposes of assessing sound levels with MONM, the sound field was modeled up to distances of 2 and 20 km from the FPSO (Scenarios 1 and 2) and the drill ship (Scenario 3), with a horizontal separation of 5 and 20 m between receiver points along the modeled radials. The horizontal angular separation between radials was 2.5°, for a total of N = 144 radial planes. Receiver depths were chosen to span the entire water column over the modeled areas, from 1 to 5000 m, with step sizes increasing with depth.

FWRAM modeled synthetic pulses of the VSP source up to 20 km, along four radials (0, 90, 180, and 270° from the tow direction) to compute peak pressure levels. The horizontal range step was set at 20 m. The tow direction was 293°. The same parameters were used to model sound from pile driving operations, the range step was however adjusted to 2 m up to 200 m from the source, and 25 m thereafter.

5. Results

5.1. Source Levels

5.1.1. Vessels

Figures 10–14 show the estimated 1/3-octave-band source levels for the modeled vessels. The broadband (10 Hz to 32 kHz) source levels vary from 173.4 dB re 1 µPa for the light construction and field intervention vessel to 196.1 dB re 1 µPa for the large tug. Although source levels may vary substantially during different operations, these modeled spectra represent a conservative average over a 24 hour period.

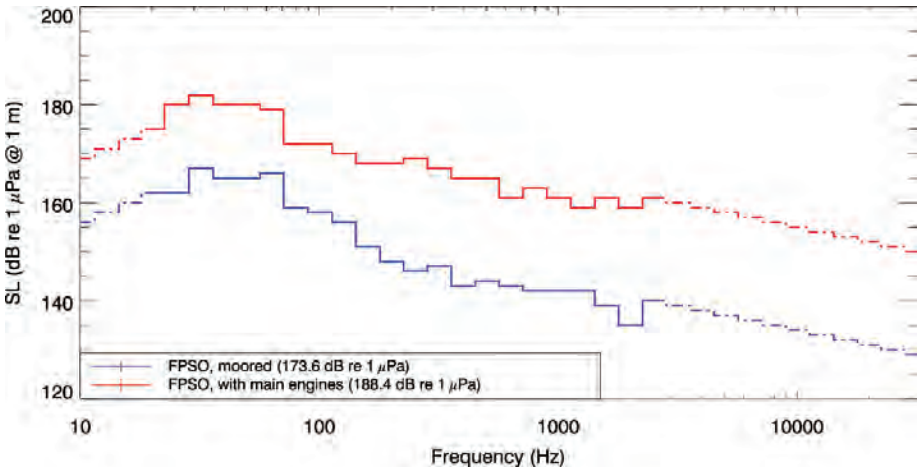

Figure 10. Estimated source level spectra for the FPSO. Dashed lines represent extrapolated levels based on Ross' spectrum (Ross 1976).

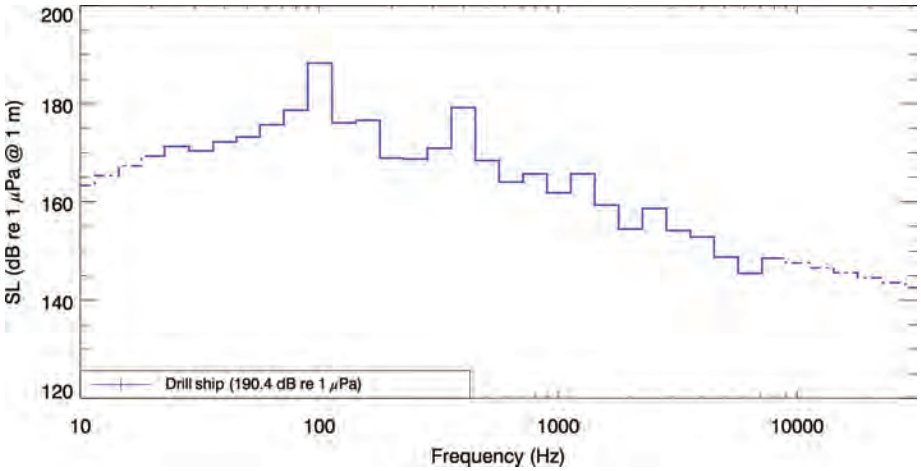

Figure 11. Estimated source level spectrum for the drill ship. Dashed lines represent extrapolated levels based on Ross' spectrum (Ross 1976).

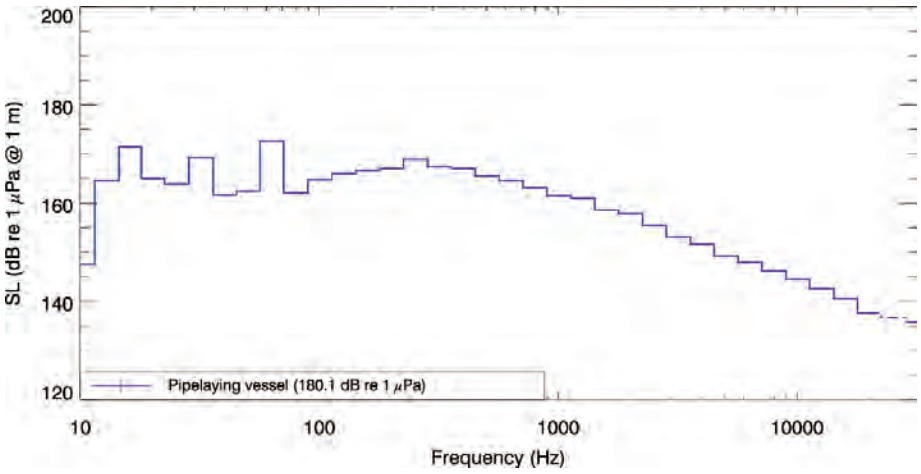

Figure 12. Estimated source level spectrum for the pipelaying vessel. Dashed lines represent extrapolated levels based on Ross' spectrum (Ross 1976).

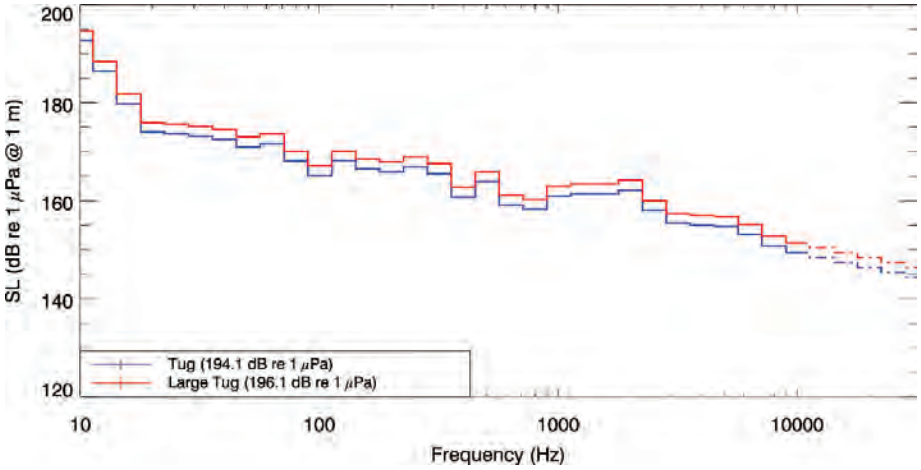

Figure 13. Estimated source level spectra for the tugs. Dashed lines represent extrapolated levels based on Ross' spectrum (Ross 1976).

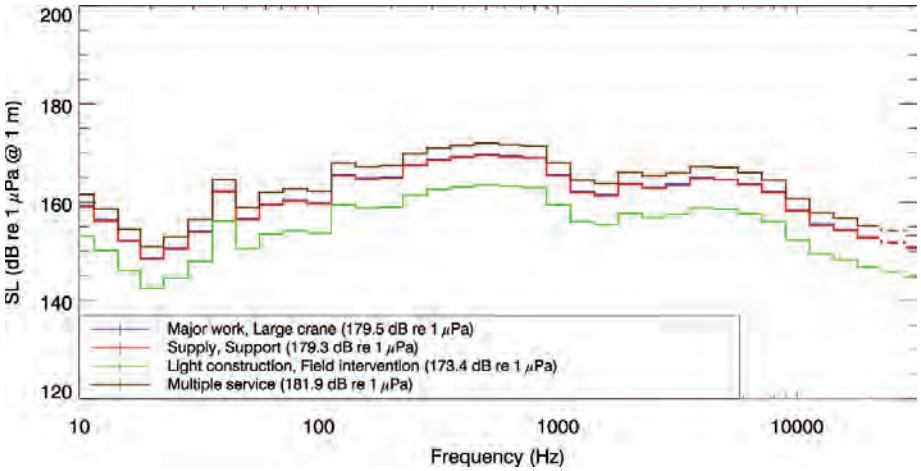

Figure 14. Estimated source level spectra for the various support vessels. Dashed lines represent extrapolated levels based on Ross' spectrum (Ross 1976).

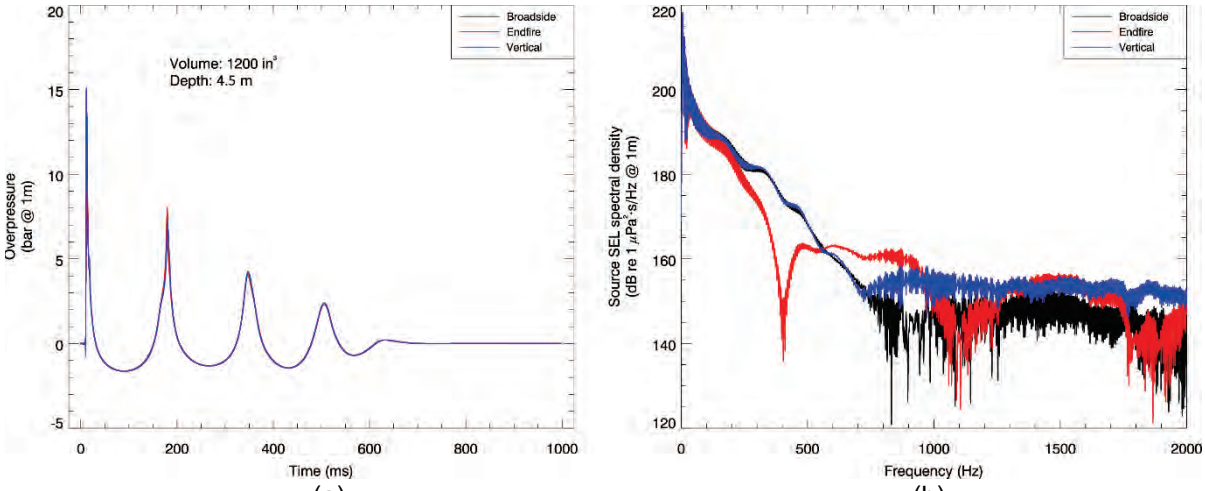
5.1.2. Vertical Seismic Profile Source

The pressure signatures of the individual array elements and the composite 1/3-octave-band source levels of the array, as functions of azimuthal angle (in the horizontal plane), were modeled with AASM (Section 3.1.2). While effects of surface reflected signals on bubble oscillations and inter-bubble interactions are accounted for in the notional pressure signatures of each element by AASM, the surface-reflected signal (i.e., surface ghost) is not shown in the far-field source signature plots below. The acoustic propagation models account for those surface reflections, which are a property of the propagating medium rather than the source.

Figure 15 shows the horizontal overpressure signatures (broadside–perpendicular to the tow direction, and endfire–parallel to the tow direction), the vertical overpressure signature, and corresponding power spectrum levels for the 1200 in^3 array at a 4.5 m tow depth. The signatures consist of a strong primary peak, related to the initial release of high-pressure air, followed by a series of pulses associated with bubble oscillations. Most energy is produced at frequencies below 600 Hz. Frequency-dependent peaks and nulls in the spectrum result from interference among elements in the array, and depend on the volumes and relative locations of the element.

Table 6 shows the broadband SPL and unweighted per-pulse SEL source levels.

Horizontal 1/3-octave-band source levels are shown as a function of band center frequency and azimuth (Figure 16). As discussed in Section 3.1.1, directivity in the sound field is most noticeable at frequencies from ~316 to 2000 Hz.



(a) (b)

Figure 15. Predicted source level details for the 1200 in^3 array. (a) The overpressure signature and (b) the power spectrum in the broadside (perpendicular to tow direction), endfire (directly aft of the array), and downward (vertical) directions.

Table 6. Source level specifications in the horizontal plane for the 1200 in^3 array, for a 4.5 m tow depth.

Direction	Peak pressure level (dB re 1 **µPa @ 1** m)	SPL (dB re 1 **µPa @** 1 m)	Unweighted per-pulse SEL (dB re 1 **µPa**^{2}·s **@** 1 m)	
			10–2000 Hz	2000–25000 Hz
Broadside (no surface ghost)	243.5	225.7	219.4	172.8
Endfire (no surface ghost)	242.6	225.6	219.3	176.9
Vertical (no surface ghost)	243.6	225.7	219.4	176.4
Vertical (with surface ghost)	243.6	224.3	219.8	179.4

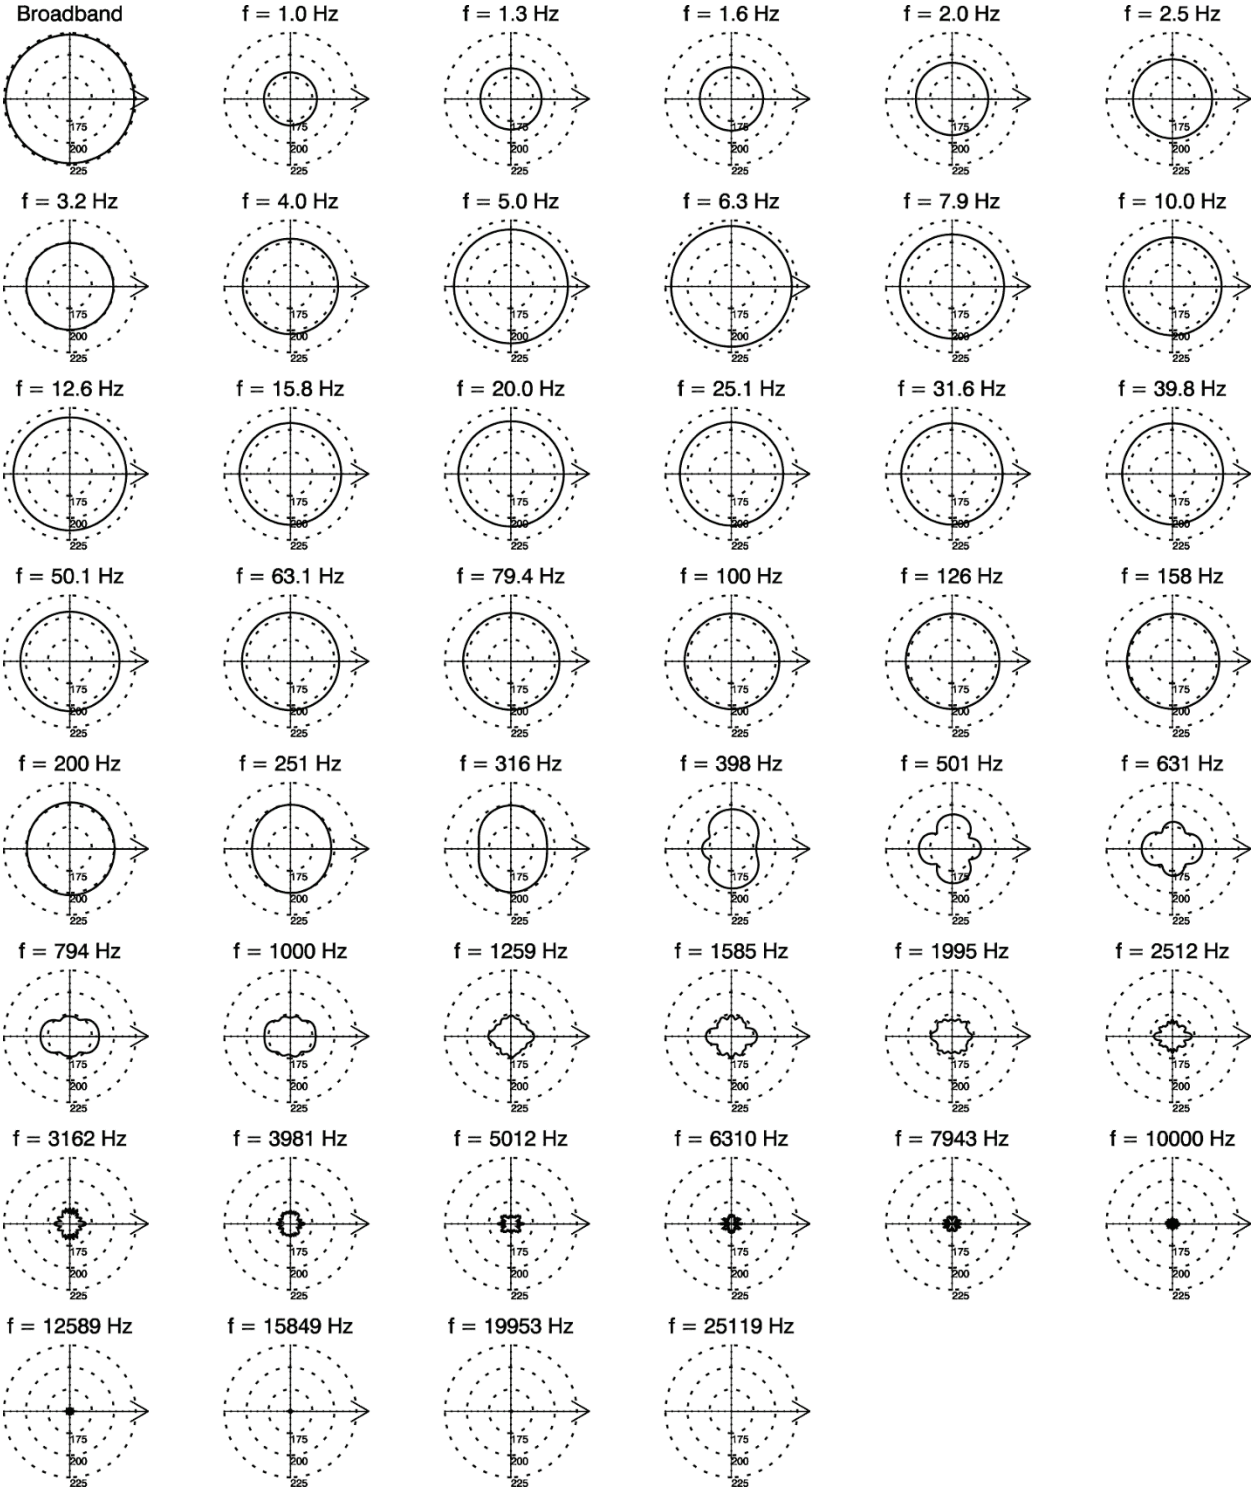


Figure 16. Directionality of the predicted horizontal source levels for the 1200 in^3 array, 10–25,000 Hz.Source levels (in dB re 1 µPa^2·s) are shown as a function of azimuth for the center frequencies of the 1/3-octave-bands modeled; frequencies are shown above the plots. Tow direction is to the right and tow depth is 4.5 m.

5.1.3. Impact Pile Driving

The forcing function at the top of the pile (Figure 17) was modeled using the GRLWEAP 2010 wave equation model. The forcing function consists of a strong primary peak, related to the initial contact of the ram and helmet, followed by a series of pulses associated with the ram-helmet oscillations. JASCO's pile driving source model estimated equivalent source signatures every 2 m along the pile. Figure 18 presents the signature of the monopoles at the top, center, and bottom of the pile. The first peak of these signatures represents the initial pile deformation traveling down the pile; its amplitude decreases and arrival time increases with depth along the pile.

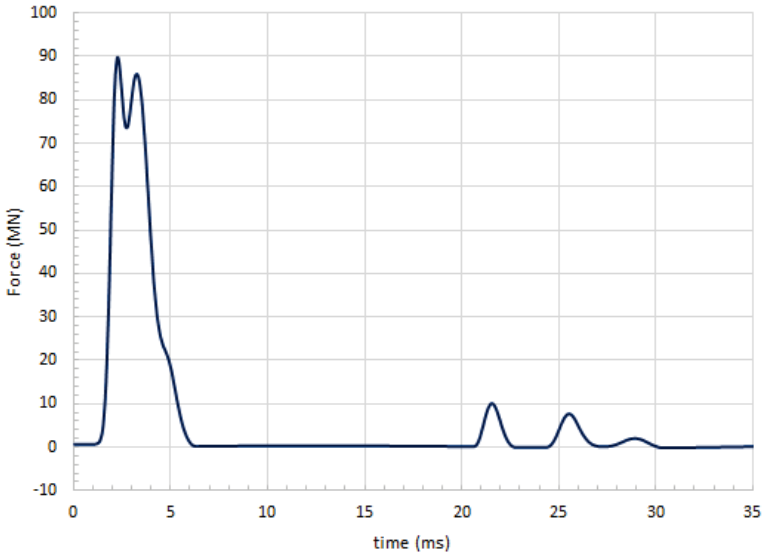

Figure 17. Force at the top of a pile during impact driving of a 25-m long, 5-m wide cylindrical steel pile with the MENCK 500T (underwater) hammer.

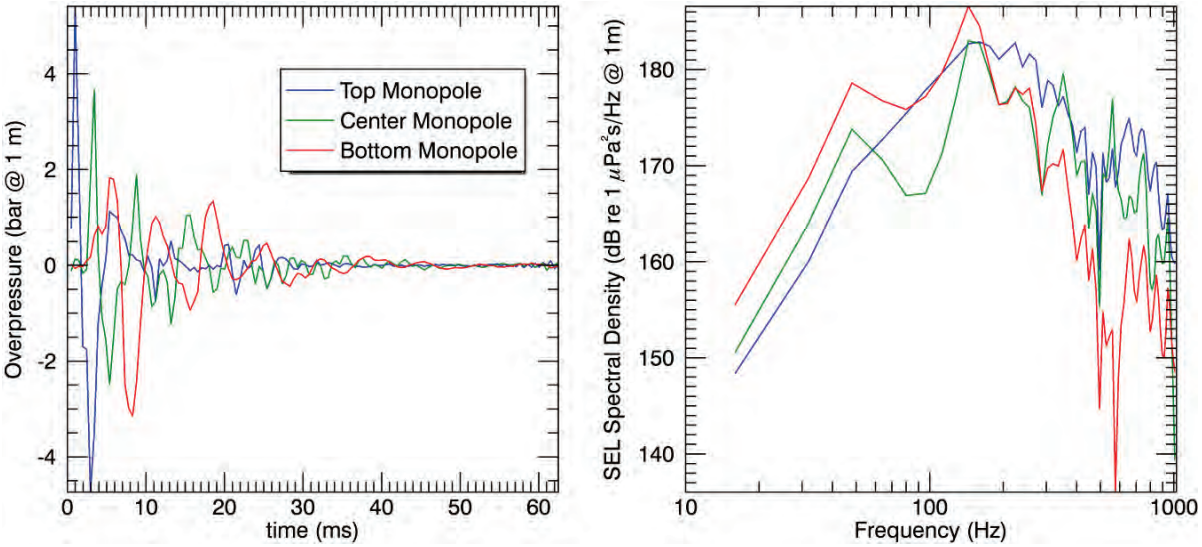

Figure 18. Predicted overpressure signature of three monopoles along the modeled pile: top (in water), center (in water), and bottom (in substrate).

5.2. Sound Fields

5.2.1. Vessels

This section includes the distances to marine mammal injury thresholds resulting from the presence of vessels (Table 7). For the purpose of estimating M-weighted SEL_{24h} in this study, all vessels were assumed stationary, operating over 90% of a 24 hour period. Peak pressure level thresholds for injury criteria were not reached; distances to peak pressure levels are not presented below.

The tabulated values represent the maximum R_{max} and $R_{95\%}$ from any vessels present in a scenario.

Table 7. Scenarios 1–3: Distances (m) to marine mammal injury for non-impulsive sources.

Hearing group	Southall et al. (2007)			Finneran (2015)		
	Threshold (M-weighted SEL_{24h}; dB re 1 µPa²·s)	R_{max} (m)	$R_{95\%}$ (m)	Threshold (M-weighted SEL_{24h}; dB re 1 µPa²·s)	R_{max} (m)	$R_{95\%}$ (m)

Mid-frequency cetaceans	215	< 5	< 5	199	-	-

5.2.2. Vertical Seismic Profile Source

This section presents the distances to marine mammal injury thresholds for the VSP source in Scenario 4. To estimate distances to marine mammal injury thresholds in M-weighted SEL_{24h}, one operational period was modeled (i.e., it was assumed that the VSP source produces 40 pulses in 24 hours). Distances to peak pressure level thresholds are either not reached or less than distances to M-weighted SEL_{24h} thresholds for injury criteria (Table 8); distances to peak pressure levels are not presented below. In Figure 19, area ensonified at or above injury thresholds are compared; the range to the Mid-frequency cetacean injury threshold based on Finneran (2015) was below the minimum resolvable range.

Table 8. Scenario 4: Distances (m) to marine mammal injury thresholds for the VSP source.

Hearing group	Southall et al. (2007)			Finneran (2015)		
	Threshold (M-weighted SEL_{24h}; dB re 1 µPa²·s)	R_{max} (m)	$R_{95\%}$ (m)	Threshold (M-weighted SEL_{24h}; dB re 1 µPa²·s)	R_{max} (m)	$R_{95\%}$ (m)

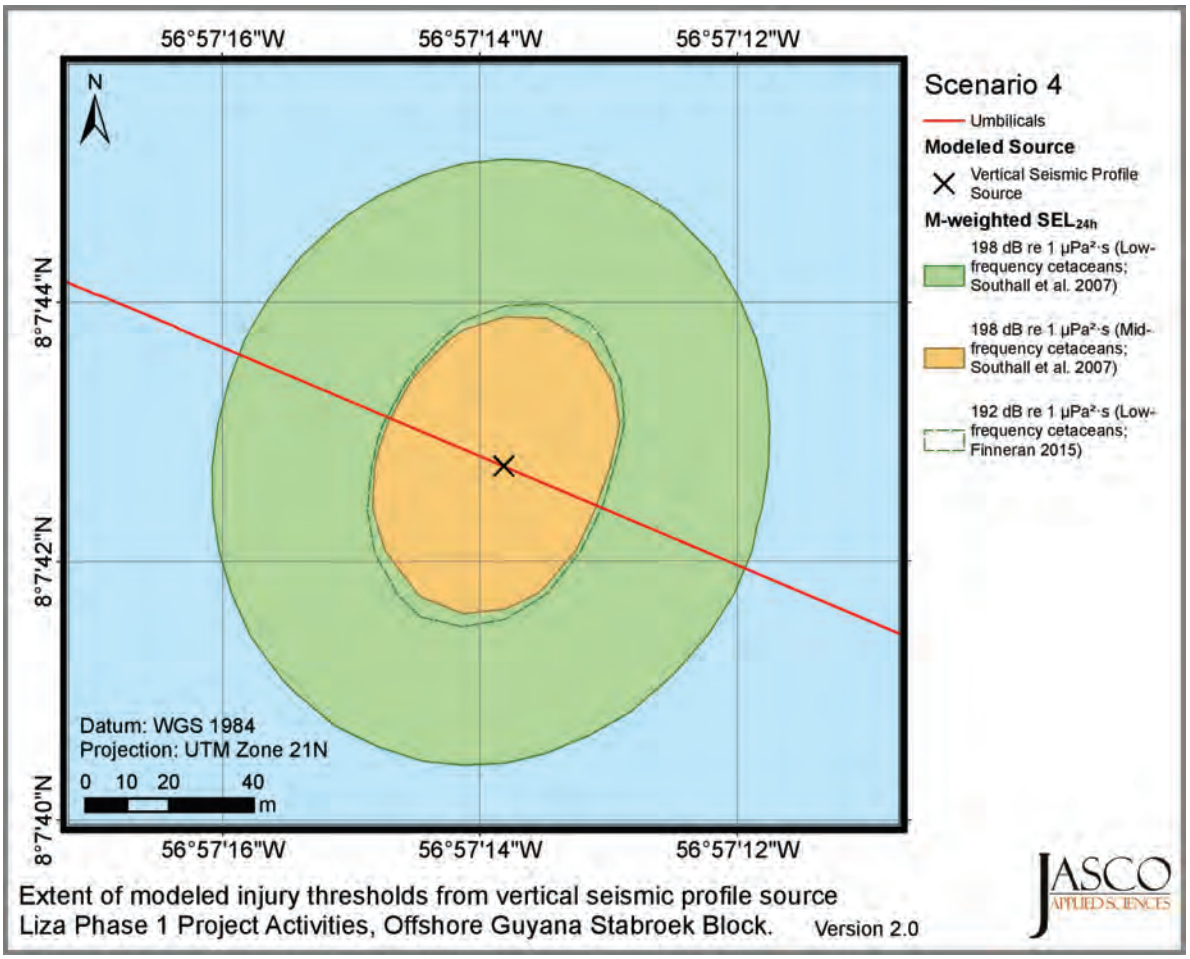

Figure 19. Scenario 4: Sound level contour map showing the extend of the maximum-over-depth M-weighted SEL_{24h} from the VSP source for marine mammal injury thresholds based on Southall et al. (2007) and Finneran (2015).

5.2.3. Impact Pile Driving

This section presents the distances to marine mammal injury thresholds for the underwater pile driving operations in Scenarios 5 and 6. To estimate distances to marine mammal injury thresholds in M-weighted SEL_{24h}, we assumed that one pile was driven for 5 hours, at a rate of 38 strikes per minute, every 24 hours. Distances to peak pressure level thresholds were either not reached or were less than distances to M-weighted SEL_{24h} thresholds for injury criteria; distances to peak pressure levels are not presented.

Tables 9–10, and Figures 20–23, present the distances to marine mammal injury thresholds at Drill Center 2-P and the FPSO, respectively. Figures 21–22 and 24–25 present vertical slices of the corresponding M-weighted SEL_{24h} fields, east of the piles. The parabolic equation (PE) approximation used in FWRAM (Section 3.2) is estimated to be valid for sound propagating up to 45° from the horizontal plane at the source depth. This angle is indicated by the black dash line in each slice.

Table 9. Scenario 5: Distances (m) to marine mammal injury thresholds for the underwater pile driving operations at Drill Center 2-P.

Hearing group	Southall et al. (2007)		Finneran (2015)	
	Threshold (M-weighted SEL_{24h}; dB re 1 µPa²·s)	R_{max} (m)	Threshold (M-weighted SEL_{24h}; dB re 1 µPa²·s)	R_{max} (m)
Low-frequency cetaceans	198	1,300	192	1,025
Mid-frequency cetaceans	198	762	187	136

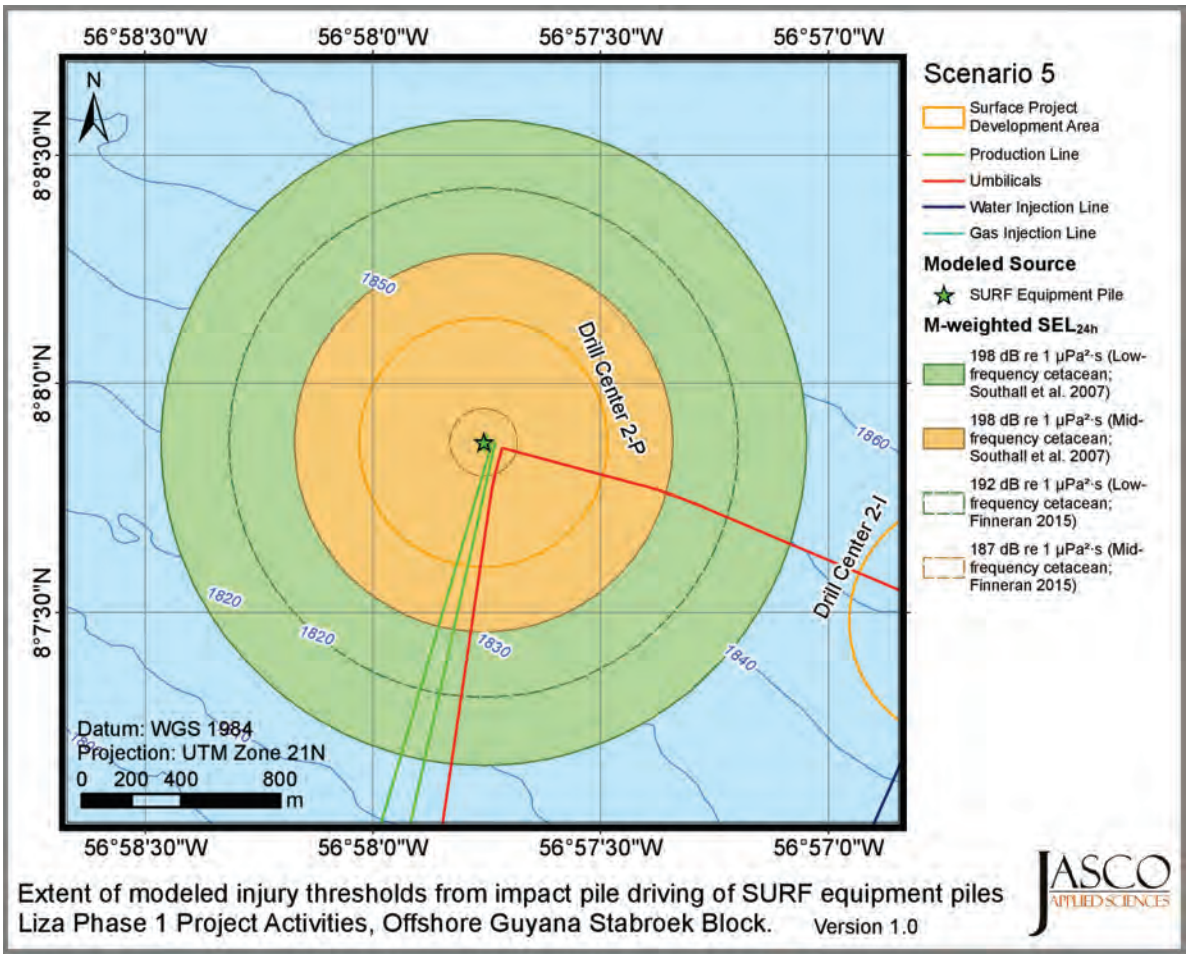

Figure 20. Scenario 5: Sound level contour map showing the extend of the maximum-over-depth M-weighted SEL_{24h} from impact pile driving for marine mammal injury thresholds based on Southall et al. (2007) and Finneran (2015).

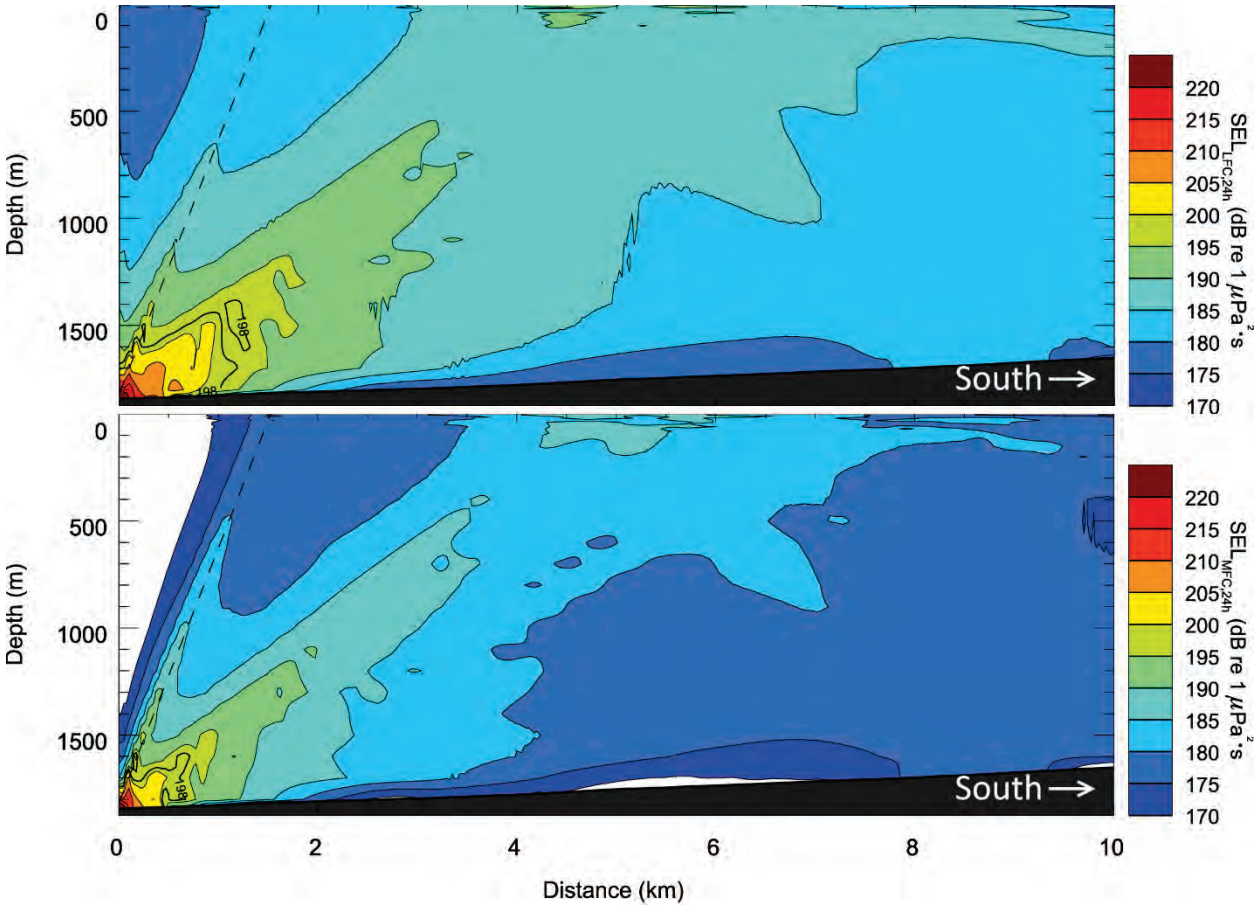

Figure 21. Scenario 5: Estimated M-weighted SEL_{24h} based on Southall et al. (2007), propagating south of the pile at Drill Center 2-P. The thicker black lines indicate sound level isopleths corresponding to the injury thresholds for (top) low- and (bottom) mid-frequency cetaceans. The dash line indicates the limiting angle below which the model is valid; received levels above the source (left of the dash line) are expected to be underestimated. The dark area at the bottom of the plot shows decreasing water depth.

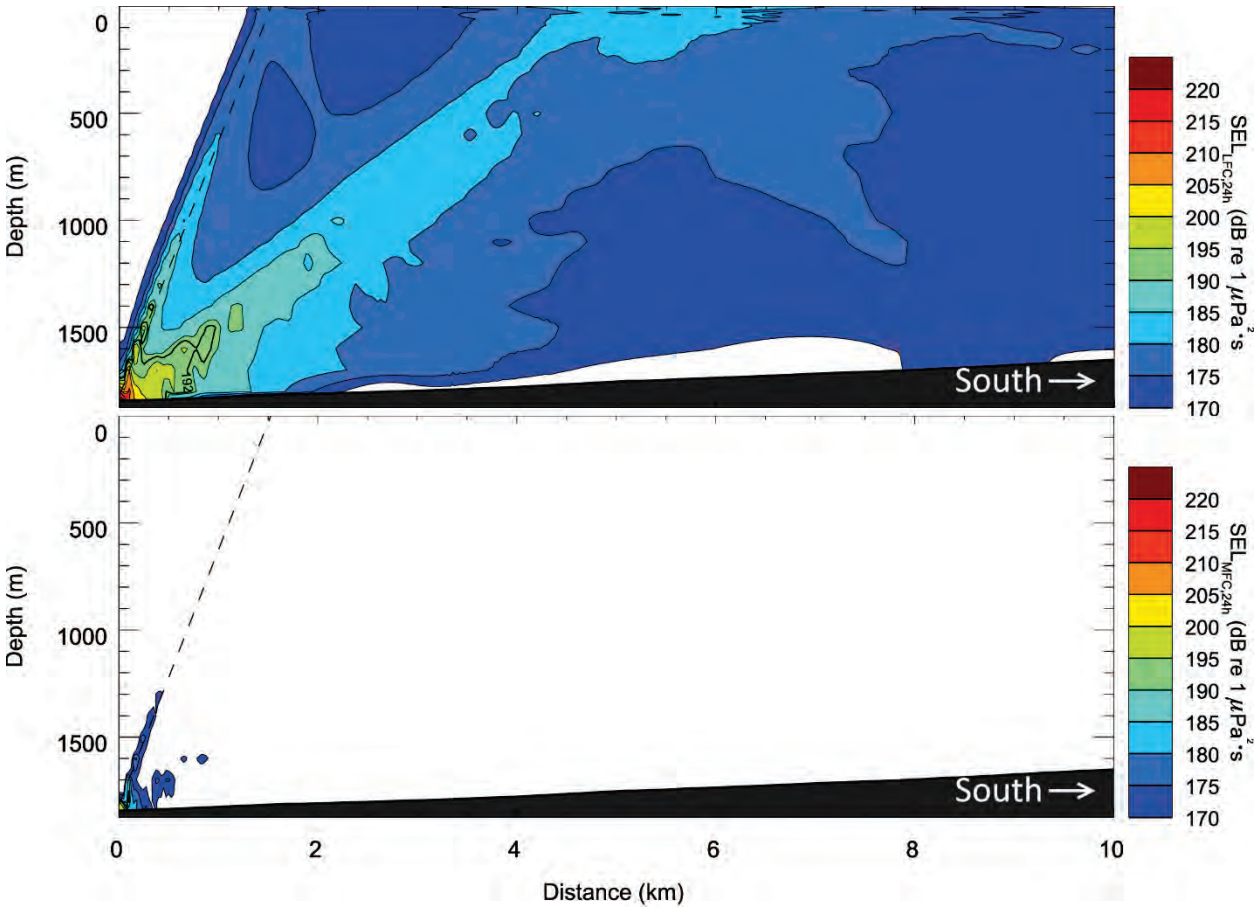

Figure 22. Scenario 5: Estimated M-weighted SEL_{24h} based on Finneran (2015), propagating south of the pile at Drill Center 2-P. The thicker black lines indicate sound level isopleths corresponding to the injury thresholds for (top) low- and (bottom) mid-frequency cetaceans. The dash line indicates the limiting angle below which the model is valid; received levels above the source (left of the dash line) are expected to be underestimated. The dark area at the bottom of the plot shows decreasing water depth.

Table 10. Scenario 6: Distances (m) to marine mammal injury thresholds for the underwater pile driving operations at the FPSO location.

Hearing group	Southall et al. (2007)		Finneran (2015)	
	Threshold (M-weighted SEL_{24h}; dB re 1 µPa²·s)	R_{max} (m)	Threshold (M-weighted SEL_{24h}; dB re 1 µPa²·s)	R_{max} (m)
Low-frequency cetaceans	198	1,375	192	1,075
Mid-frequency cetaceans	198	725	187	100

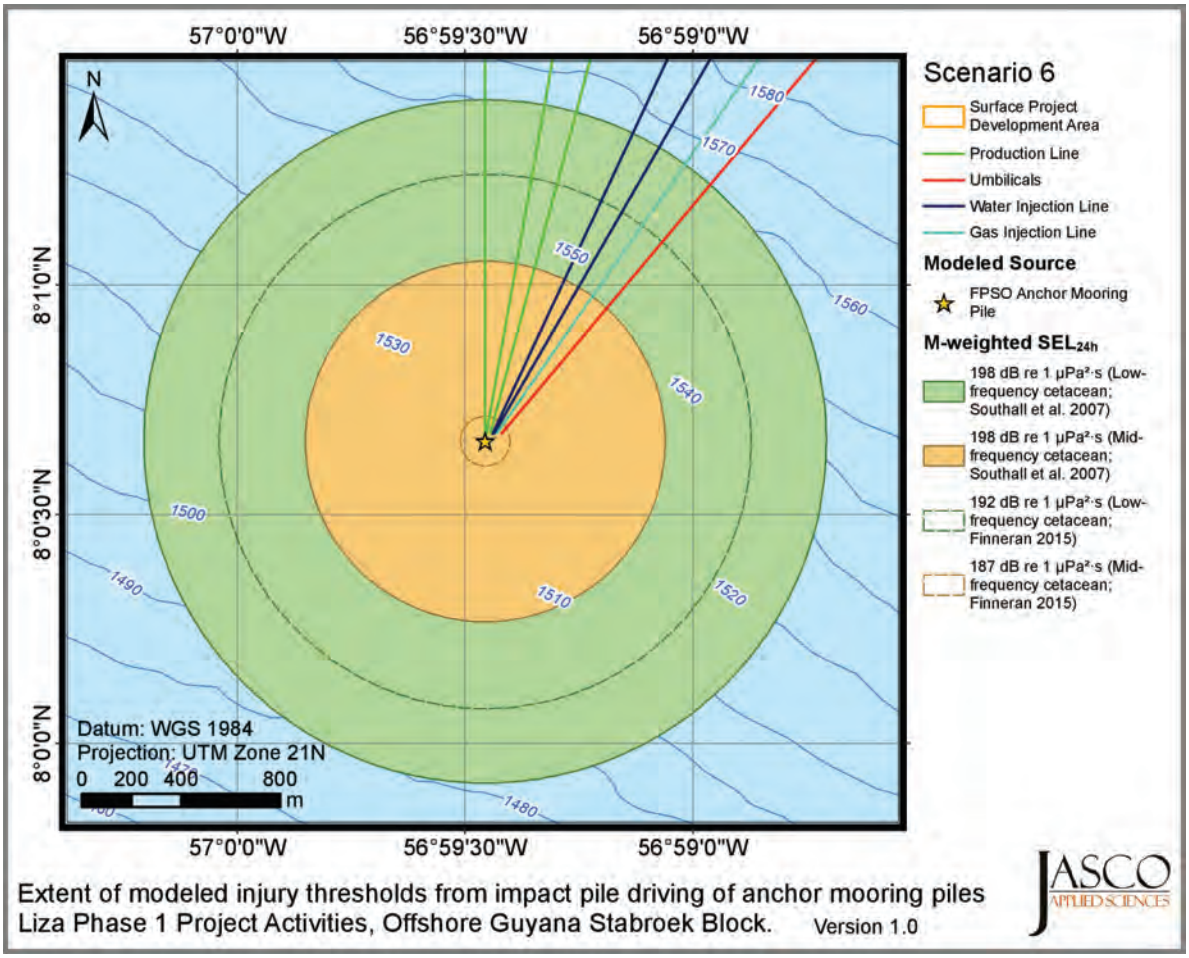

Figure 23. Scenario 6: Sound level contour map showing the extend of the maximum-over-depth M-weighted SEL_{24h} from impact pile driving for marine mammal injury thresholds based on Southall et al. (2007) and Finneran (2015).

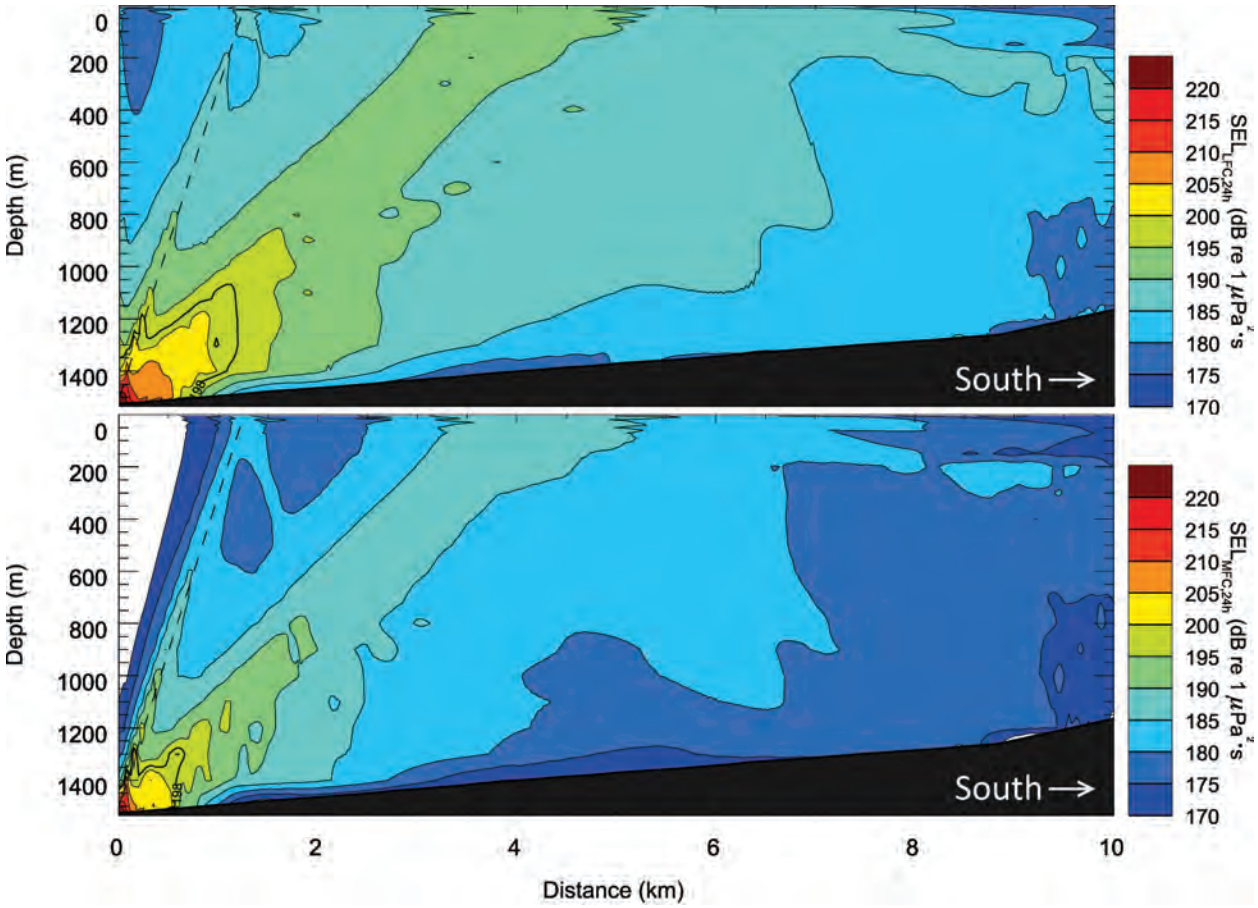

Figure 24. Scenario 6: Estimated M-weighted SEL_{24h} based on Southall et al. (2007), propagating south of the FPSO anchor mooring piles. The thicker black lines indicate sound level isopleths corresponding to the injury thresholds for (top) low- and (bottom) mid-frequency cetaceans. The dash line indicates the limiting angle below which the model is valid; received levels above the source (left of the dash line) are expected to be underestimated. The dark area at the bottom of the plot shows decreasing water depth.

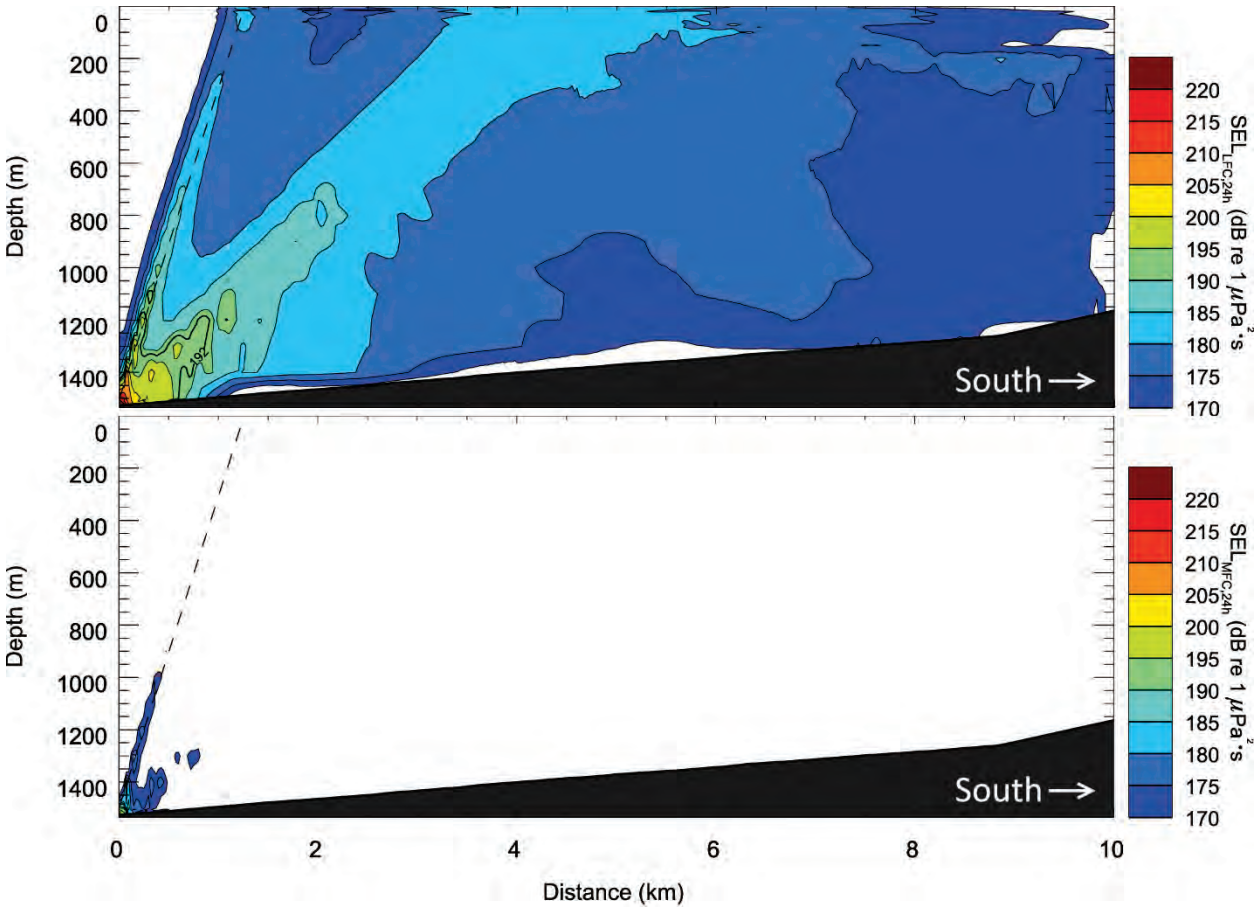

Figure 25. Scenario 6: Estimated M-weighted SEL_{24h} based on Finneran (2015), propagating south of the FPSO anchor mooring piles. The thicker black lines indicate sound level isopleths corresponding to the injury thresholds for (top) low- and (bottom) mid-frequency cetaceans. The dash line indicates the limiting angle below which the model is valid; received levels above the source (left of the dash line) are expected to be underestimated. The dark area at the bottom of the plot shows decreasing water depth.

6. Discussion

The estimated broadband source levels of vessels varied from 173.4 dB re 1 µPa at 1 m for the light construction and field intervention vessels, to 196.1 dB re 1 µPa at 1m for the large tug. Although source levels may vary substantially during operations, the modeled source level spectra of the vessels represent conservative averages over a 24 hour period.

For scenarios 1 through 3, the distances to injury thresholds from vessels were small: <10 m for all species, thus essentially insignificant relative to the size of the vessels. The distances to injury thresholds were similar for Southall et al. (2007) and Finneran (2015) criteria (Table 7). These results assume that the vessels were stationary for 24 hours and the animal was present within the stated distance for the entire accumulation period (24 hours).

The broadband (10–25,000 Hz) per-pulse SEL source level of the VSP source was 219–220 dB re 1 µPa^2·s @ 1 m in all directions (Table 6). Distances (R_{max}) to injury thresholds for mid-frequency cetaceans were 35 m based on Southall et al. (2007) and below the minimum resolvable range based on Finneran (2015); for low-frequency cetaceans they were 73 and 39 m, respectively (Table 8). For this source, the injury thresholds based on Finneran (2015) were generally lower than for Southall et al. (2007) due to the steeper roll-off at low frequencies of the weighting functions for the former. Because most of the energy from the VSP source lies below 600 Hz (Figure 15), Finneran's weighting yields a greater discount than Southall et al. (2007) (see Appendix A.4).

Distances to injury thresholds were longer for impact pile driving than for other operations. Across both modelled sites, for mid-frequency cetaceans the maximum ranges were 762 m based on Southall et al. (2007) and 136 m based on Finneran (2015); for low-frequency cetaceans they were 1,375 m and 1,075 m, respectively (Tables 9–10). The differences in ranges between the two sites were minor. The sound levels at or above injury thresholds were found close to the ocean bottom, at depths >1,000 m. Low-frequency cetacean species present in the area are not expected to dive to those depths and, therefore, should never be exposed to injurious sound levels from pile driving activities. A few species within the mid-frequency hearing group, such as some dolphins, may feed at depths greater than 1,000 m and could therefore be affected by pile driving sound. The amount of time these animals spend below 1,000 m is, however, limited due to their need to resurface to breathe, which reduces the probability of injury.

Glossary

1/3-octave-band
Non-overlapping passbands that are one-third of an octave wide (where an octave is a doubling of frequency). Three adjacent 1/3-octave-bands make up one octave. One-third-octave-bands become wider with increasing frequency. See also octave.

90%-energy time window
The time interval over which the cumulative energy rises from 5% to 95% of the total pulse energy. This interval contains 90% of the total pulse energy. Symbol: T_{90}.

90% root-mean-square sound pressure level (90% SPL)
The root-mean-square sound pressure levels calculated over the 90%-energy time window of a pulse. Used only for pulsed sounds.

Air gun
A device that has a chamber of compressed air, which is “fired” (quickly released) to produce a pulse of acoustic energy.

A-weighting
Frequency-selective weighting for human hearing in air that is derived from the inverse of the idealized 40-phon equal loudness hearing function across frequencies.

absorption
The conversion of acoustic energy into heat, which is captured by insulation.

ambient noise
All-encompassing sound at a given place, usually a composite of sound from many sources near and far (ANSI S1.1-1994 R2004), e.g., shipping vessels, seismic activity, precipitation, sea ice movement, wave action, and biological activity.

attenuation
The gradual loss of acoustic energy from absorption and scattering as sound propagates through a medium.

auditory weighting function (frequency-weighting function)
Auditory weighting functions account for marine mammal hearing sensitivity. They are applied to sound measurements to emphasize frequencies that an animal hears well and de-emphasize frequencies they hear less well or not at all (Southall et al. 2007, Finneran and Jenkins 2012, NOAA 2013).

azimuth
A horizontal angle relative to a reference direction, which is often magnetic north or the direction of travel. In navigation it is also called bearing.

background noise
Total of all sources of interference in a system used for the production, detection, measurement, or recording of a signal, independent of the presence of the signal (ANSI S1.1-1994 R2004). Ambient noise detected, measured, or recorded with a signal is part of the background noise.

bandwidth
The range of frequencies over which a sound occurs. Broadband refers to a source that produces sound over a broad range of frequencies (e.g., seismic sources, vessels) whereas narrowband sources produce sounds over a narrow frequency range (e.g., sonar) (ANSI/ASA S1.13-2005 R2010).

bar
Unit of pressure equal to 100 kPa, which is approximately equal to the atmospheric pressure on Earth at sea level. 1 bar is equal to 10^6 Pa or 10^{11} µPa.

broadband sound level
The total sound pressure level measured over a specified frequency range. If the frequency range is unspecified, it refers to the entire measured frequency range.

broadside direction
Perpendicular to the travel direction of a source. Compare with endfire direction.

cavitation
A rapid formation and collapse of vapor cavities (i.e., bubbles or voids) in water, most often caused by a rapid change in pressure. Fast-spinning vessel propellers typically cause cavitation, which creates a lot of sound.

cetacean
Any animal in the order Cetacea. These are aquatic, mostly marine mammals and include whales, dolphins, and porpoises.

compressional wave
A mechanical vibration wave in which the direction of particle motion is parallel to the direction of propagation. Also called primary wave or P-wave.

continuous sound
A sound whose sound pressure level remains above ambient sound during the observation period (ANSI/ASA S1.13-2005 R2010). A sound that gradually varies in intensity with time, for example, sound from a marine vessel.

decibel (dB)
One-tenth of a bel. Unit of level when the base of the logarithm is the tenth root of ten, and the quantities concerned are proportional to power (ANSI S1.1-1994 R2004).

endfire direction
Parallel to the travel direction of a source. See also broadside direction.

ensonified
Exposed to sound.

equal-loudness contour
A curve or curves that show, as a function of frequency, the sound pressure level required to cause a given loudness for a listener having normal hearing, listening to a specified kind of sound in a specified manner (ANSI S1.1-1994 R2004).

far-field
The zone where, to an observer, sound originating from an array of sources (or a spatially-distributed source) appears to radiate from a single point. The distance to the acoustic far-field increases with frequency.

fast-average sound pressure level
The time-averaged sound pressure levels calculated over the duration of a pulse (e.g., 90%-energy time window), using the leaky time integrator from Plomp and Bouman (1959) and a time constant of 125 ms. Used only for pulsed sounds.

fast Fourier transform (FFT)
A computationally efficiently algorithm for computing the discrete Fourier transform.

frequency
The rate of oscillation of a periodic function measured in cycles-per-unit-time. The reciprocal of the period. Unit: hertz (Hz). Symbol: *f*. 1 Hz is equal to 1 cycle per second.

geoacoustic
Relating to the acoustic properties of the seabed.

hearing group
Grouping of marine mammal species with similar hearing ranges. Commonly defined hearing groups include low-, mid-, and high-frequency cetaceans, pinnipeds in water, and pinnipeds in air.

hearing threshold
The sound pressure level that is barely audible for a given individual in the absence of significant background noise during a specific percentage of experimental trials.

hertz (Hz)
A unit of frequency defined as one cycle per second.

high-frequency cetacean
The functional hearing group that represents odontocetes specialized for using high frequencies.

intermittent sound
A level of sound that abruptly drops to the background noise level several times during the observation period.

impulsive sound
Sound that is typically brief and intermittent with rapid (within a few seconds) rise time and decay back to ambient levels (NOAA 2013, ANSI S12.7-1986 R2006). For example, seismic sources and impact pile driving.

low-frequency cetacean
The functional hearing group that represents mysticetes (baleen whales).

mid-frequency cetacean
The functional hearing group that represents some odontocetes (dolphins, toothed whales, beaked whales, and bottlenose whales).

M-weighting
The process of band-pass filtering loud sounds to reduce the importance of inaudible or less-audible frequencies for broad classes of marine mammals. “Generalized frequency weightings for various functional hearing groups of marine mammals, allowing for their functional bandwidths and appropriate in characterizing auditory effects of strong sounds” (Southall et al. 2007).

mysticete
Mysticeti, a suborder of cetaceans, use their baleen plates, rather than teeth, to filter food from water. They are not known to echolocate, but use sound for communication. Members of this group include rorquals (Balaenopteridae), right whales (Balaenidae), and the gray whale (*Eschrichtius robustus*).

non-impulsive sound
Sound that is broadband, narrowband or tonal, brief or prolonged, continuous or intermittent, and typically does not have a high peak pressure with rapid rise time (typically only small fluctuations in decibel level)

that impulsive signals have (ANSI/ASA S3.20-1995 R2008). For example, marine vessels, aircraft, machinery, construction, and vibratory pile driving (NIOSH 1998, NOAA 2015).

octave
The interval between a sound and another sound with double or half the frequency. For example, one octave above 200 Hz is 400 Hz, and one octave below 200 Hz is 100 Hz.

odontocete
The presence of teeth, rather than baleen, characterizes these whales. Members of the Odontoceti are a suborder of cetaceans, a group comprised of whales, dolphins, and porpoises. The toothed whales' skulls are mostly asymmetric, an adaptation for their echolocation. This group includes sperm whales, killer whales, belugas, narwhals, dolphins, and porpoises.

otariid
A common term used to describe members of the Otariidae, eared seals, commonly called sea lions and fur seals. Otariids are adapted to a semi-aquatic life; they use their large fore flippers for propulsion. Their ears distinguish them from phocids. Otariids are one of the three main groups in the superfamily Pinnipedia; the other two groups are phocids and walrus.

parabolic equation method
A computationally-efficient solution to the acoustic wave equation that is used to model transmission loss. The parabolic equation approximation omits effects of back-scattered sound, simplifying the computation of transmission loss. The effect of back-scattered sound is negligible for most ocean-acoustic propagation problems.

peak sound pressure level (peak SPL)
The maximum instantaneous sound pressure level, in a stated frequency band, within a stated period. Also called zero-to-peak sound pressure level. Unit: decibel (dB).

percentile level, exceedance
The sound level exceeded *n* % of the time during a measurement.

permanent threshold shift (PTS)
A permanent loss of hearing sensitivity caused by excessive acoustic exposure. PTS is considered auditory injury.

phocid
A common term used to describe all members of the family Phocidae. These true/earless seals are more adapted to in-water life than are otariids, which have more terrestrial adaptations. Phocids use their hind flippers to propel themselves. Phocids are one of the three main groups in the superfamily Pinnipedia; the other two groups are otariids and walrus.

pinniped
A common term used to describe all three groups that form the superfamily Pinnipedia: phocids (true seals or earless seals), otariids (eared seals or fur seals and sea lions), and walrus.

point source
A source that radiates sound as if from a single point (ANSI S1.1-1994 R2004).

power spectrum density
The acoustic signal power per unit frequency as measured at a single frequency. Unit: $\mu Pa^2/Hz$, or $\mu Pa^2 \cdot s$.

power spectral density level
The decibel level ($10\log_{10}$) of the power spectrum density, usually presented in 1 Hz bins. Unit: dB re 1 $\mu Pa^2/Hz$.

pressure, acoustic
The deviation from the ambient hydrostatic pressure caused by a sound wave. Also called overpressure. Unit: pascal (Pa). Symbol: *p*.

pressure, hydrostatic
The pressure at any given depth in a static liquid that is the result of the weight of the liquid acting on a unit area at that depth, plus any pressure acting on the surface of the liquid. Unit: pascal (Pa).

received level
The sound level measured at a receiver.

Root-mean-square sound pressure level (SPL)
See sound pressure level.

shear wave
A mechanical vibration wave in which the direction of particle motion is perpendicular to the direction of propagation. Also called secondary wave or S-wave. Shear waves propagate only in solid media, such as sediments or rock. Shear waves in the seabed can be converted to compressional waves in water at the water-seabed interface.

signature
Pressure signal generated by a source.

sound
A time-varying pressure disturbance generated by mechanical vibration waves travelling through a fluid medium such as air or water.

sound exposure
Time integral of squared, instantaneous frequency-weighted sound pressure over a stated time interval or event. Unit: pascal-squared second ($Pa^2 \cdot s$) (ANSI S1.1-1994 R2004).

sound exposure level (SEL)
A cumulative measure related to the sound energy in one or more pulses. Unit: dB re 1 $\mu Pa^2 \cdot s$. SEL is expressed over the summation period (e.g., per-pulse SEL [for seismic sources], single-strike SEL [for pile drivers], 24-hour SEL).

sound field
Region containing sound waves (ANSI S1.1-1994 R2004).

sound pressure level (SPL)
The decibel ratio of the time-mean-square sound pressure, in a stated frequency band, to the square of the reference sound pressure (ANSI S1.1-1994 R2004).

For sound in water, the reference sound pressure is one micropascal (p_0 = 1 µPa) and the unit for SPL is dB re 1 µPa:

$$\mathrm{SPL} = 10\log_{10}\left(p^2 / p_0^2\right) = 20\log_{10}\left(p / p_0\right)$$

Unless otherwise stated, SPL refers to the root-mean-square sound pressure level. See also 90% sound pressure level and fast-average sound pressure level.

sound speed profile
The speed of sound in the water column as a function of depth below the water surface.

source level (SL)
The sound pressure level measured 1 meter from a theoretical point source that radiates the same total sound power as the actual source. Unit: dB re 1 µPa @ 1 m.

spectrum
An acoustic signal represented in terms of its power (or energy) distribution compared with frequency.

temporary threshold shift (TTS)
Temporary loss of hearing sensitivity caused by excessive acoustic exposure.

transmission loss (TL)
The decibel reduction in sound level between two stated points that results from sound spreading away from an acoustic source subject to the influence of the surrounding environment. Also called propagation loss.

wavelength
Distance over which a wave completes one oscillation cycle. Unit: meter (m). Symbol: λ.

If applied, the frequency weighting of an acoustic event should be specified, as in the case of M-weighted SEL (e.g., $L_{E,LFC,24h}$; Appendix A.3). The use of fast, slow, or impulse exponential-time-averaging or other time-related characteristics should else be specified.

A.1.1. 1/3-Octave Band Analysis

The distribution of a sound's power with frequency is described by the sound's spectrum. The sound spectrum can be split into a series of adjacent frequency bands. Splitting a spectrum into 1 Hz wide bands, called passbands, yields the power spectral density of the sound. This splitting of the spectrum into passbands of a constant width of 1 Hz, however, does not represent how animals perceive sound.

Because animals perceive exponential increases in frequency rather than linear increases, analyzing a sound spectrum with passbands that increase exponentially in size better approximates real-world scenarios. In underwater acoustics, a spectrum is commonly split into 1/3-octave-bands, which are one-third of an octave wide; each octave represents a doubling in sound frequency. The center frequency of the ith 1/3-octave-band, $f_c(i)$, is defined as:

$$f_c(i) = 10^{i/10} , \tag{A-5}$$

and the low (f_{lo}) and high (f_{hi}) frequency limits of the ith 1/3-octave-band are defined as:

$$f_{lo} = 10^{-1/20} f_c(i) \quad \text{and} \quad f_{hi} = 10^{1/20} f_c(i) . \tag{A-6}$$

The 1/3-octave-bands become wider with increasing frequency, and on a logarithmic scale the bands appear equally spaced (Figure A-1). The acoustic modeling spans from band 10 ($f_c(10)$ = 10 Hz) to band 45 ($f_c(45)$ = 32 kHz).

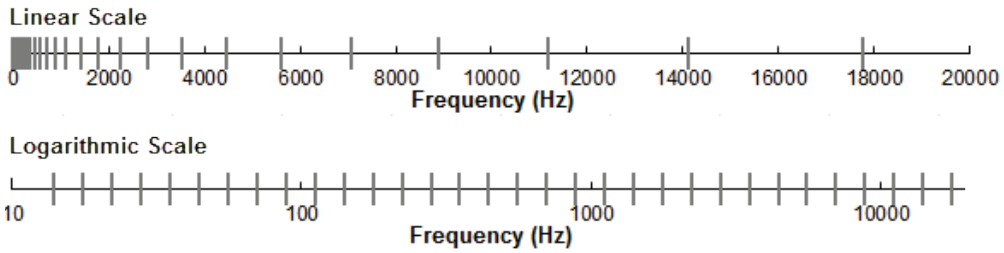

Figure A-1. One-third-octave-bands shown on a linear frequency scale and on a logarithmic scale.

The sound pressure level in the ith 1/3-octave-band $\left(L_b^{(i)}\right)$ is computed from the power spectrum $S(f)$ between f_{lo} and f_{hi}:

$$L_b^{(i)} = 10 \log_{10} \left(\int_{f_{lo}}^{f_{hi}} S(f) df \right) . \tag{A-7}$$

Summing the sound pressure level of all the 1/3-octave-bands yields the broadband sound pressure level:

$$\text{Broadband SPL} = 10 \log_{10} \sum_i 10^{L_b^{(i)}/10} . \tag{A-8}$$

Figure A-2 shows an example of how the 1/3-octave-band sound pressure levels compare to the power spectrum of an ambient noise signal. Because the 1/3-octave-bands are wider with increasing frequency, the 1/3-octave-band SPL is higher than the power spectrum, especially at higher frequencies. Acoustic

A.2.2. Vessel Sounds

Underwater sound that radiates from vessels is produced mainly by propeller and thruster cavitation, with a smaller fraction of sound produced by sound transmitted through the hull, such as by engines, gearing, and other mechanical systems. Sound levels tend to be the highest when thrusters are used to position the vessel and when the vessel is transiting at high speeds. A vessel's sound signature depends on the vessel's size, power output, propulsion system (e.g., conventional propellers vs. Voith Schneider propulsion), and the design characteristics of the given system (e.g., blade shape and size). A vessel produces broadband acoustic energy with most of the energy emitted below a few kilohertz. Sound from onboard machinery, particularly sound below 200 Hz, dominates the sound spectrum before cavitation begins—normally around 8–12 knots on many commercial vessels (Spence et al. 2007). Sound from vessels typically raises the background sound level by tenfold or more (Arveson and Vendittis 2000).

A.2.3. Vertical Seismic Profile Sources

Seismic air guns generate pulsed acoustic energy by releasing a highly compressed air bubble into the water that expands and then collapses. These sources produce frequencies from several hertz to a few kilohertz, with larger element volumes producing lower frequencies and higher sound levels.

During a vertical seismic profiling, a stationary source array is deployed from either a drill ship or a closely stationed auxiliary vessel. A single element produces an approximately omnidirectional sound field, emitting acoustic energy equally in all directions. For all seismic surveys, source array layouts and firing delays are configured to achieve higher sound energy emission levels in the vertical direction where the pulses from all elements add in-phase. Lower levels of sound energy are emitted in other directions. Source arrays might show significant directionality in the horizontal direction due to the phase delay between pulses because the elements are horizontally separated.

A.2.4. Impact Pile Driving

Impact pile driving consists of infixing piles of various shapes and materials into the ground by striking the top end of the pile with a ram. In its simplest form, pile driving is achieved by a free-falling ram directly striking the pile. After the strike, the ram is raised and the action repeated until a sufficient portion of the pile penetrates the ground. Additional equipment can be used for higher efficiency or to accomplish activities such as driving fully submerged piles. For example, free-falling pile drivers have generally been replaced by more sophisticated mechanisms that control downward and upward movement of the ram. Cushion materials can be installed between the ram and the drive head. Aside from redistributing some of the energy from the hammer impact and protecting the contact surfaces from damage, the cushion also allows some control on the maximum amplitude and duration of the force applied to the pile.

After each strike, the initial radial deformation at the top of the pile wall caused by impact compression rapidly travels downward along the pile, generating in the process a pressure wave in the water column. Because of the properties of the material, the deformation travels down the pile faster than the speed of sound in water, resulting in a radiating pressure wave that resemble a Mach cone with a cone angle of ~17° (Reinhall and Dahl 2011).

A.3. Acoustic Effect Criteria

A.3.1. Marine Mammals

It has been long recognized that marine mammals can be adversely affected by underwater anthropogenic sound. For example, Payne and Webb (1971) suggested that communication distances of fin whales are reduced by shipping sounds. Subsequently, similar concerns arose regarding effects of other underwater sound sources and the possibility that impulsive sources could cause auditory injury. This led to a series of workshops held in the late 1990s, conducted to address acoustic mitigation requirements for seismic surveys and other underwater sound sources (NMFS 1998, ONR 1998, HESS 1998, Nedwell and Turnpenny 1998, Ellison and Stein 1999).

The U.S. National Oceanic and Atmospheric Administration's (NOAA) National Marine Fisheries Service (NMFS) considered recommendations from these workshops and adopted a set of interim thresholds for assessing injury and disturbance due to both impulsive and non-impulsive, or continuous sound, types of acoustic sources (e.g., NOAA 1998). We refer to these thresholds as the NMFS SPL criteria. Regulatory agencies in many countries have applied these criteria since the early 2000s, but recent advances in assessment approaches are starting to replace them.

The NMFS SPL criteria for acoustic exposure injury to marine mammals were set according to recommendations for cautionary estimates of sound levels leading to onset of permanent hearing threshold shift (PTS). These criteria prescribe injury thresholds of 190 dB re 1 µPa SPL for pinnipeds and 180 dB re 1 µPa SPL for cetaceans (NMFS 2013). A corresponding injury threshold was not defined for non-impulsive sounds at that time. NMFS indicates that the SPL criteria should be used for all sources including sonars and explosives (NMFS 2013). These injury thresholds are applied to individual acoustic pulses and do not consider the overall duration of the sound or its acoustic frequency distribution.

Criteria that do not take into account exposure duration or acoustic spectra are generally insufficient for assessing hearing injury. Human workplace noise assessments consider the SPL as well as the duration of exposure and sound spectral characteristics. For example, the International Institute of Noise Control Engineering (I-INCE) and the Occupational Safety and Health Administration (OSHA) suggests thresholds in C-weighted peak pressure level and A-weighted time-average sound level (dB(A)[1] L_{eq}). They also suggest exchange rates that increase the allowable thresholds for each halving or doubling of exposure time. This approach assumes that hearing damage depends on the relative loudness perceived by the human ear. It also assumes that the ear might partially recover from past exposures, particularly if there are periods of quiet nested within the overall exposure.

In recognition of shortcomings of the SPL-only based injury criteria, in 2005 NMFS sponsored the Noise Criteria Group to review literature on marine mammal hearing to propose new acoustic exposure criteria (NMFS 2013). Some members of this expert group published a landmark paper (Southall et al. 2007) that suggested assessment methods similar to those applied for humans. The resulting recommendations introduced dual acoustic injury criteria for impulsive sounds that included peak pressure level thresholds and cumulative SEL_{24h} thresholds, where the subscripted *24h* refers to the 24 hour accumulation period for calculating SEL. The peak pressure level criterion is not frequency weighted whereas the SEL_{24h} is frequency weighted according to one of four marine mammal species hearing groups: Low-, Mid- and High-Frequency Cetaceans (LFC, MFC, and HFC respectively) and Pinnipeds in Water (PINN). These weighting functions are referred to as M-weighting filters (analogous to the A-weighting filter for human; Appendix A.4.1). The SEL_{24h} thresholds were obtained by extrapolating measurements of onset levels of Temporary Threshold Shift (TTS) in belugas by the amount of TTS required to produce Permanent Threshold Shift (PTS) in chinchillas. The Southall et al. (2007) recommendations do not specify an exchange rate, which suggests that the thresholds are the same regardless of the duration of exposure (i.e., it infers a 3 dB exchange rate).

[1] The "A" refers to a specific frequency-dependent filter shaped according to a human equal loudness contour.

where *G*(f) is the weighting function amplitude (in dB) at the frequency *f* (in Hz), and *a* and *b* are the estimated lower and upper hearing limits, respectively, which control the roll-off and passband of the weighting function. The parameters *a* and *b* are defined uniquely for each hearing group (Table A-1). The auditory weighting functions recommended by Southall et al. (2007) are shown in Figure A-3.

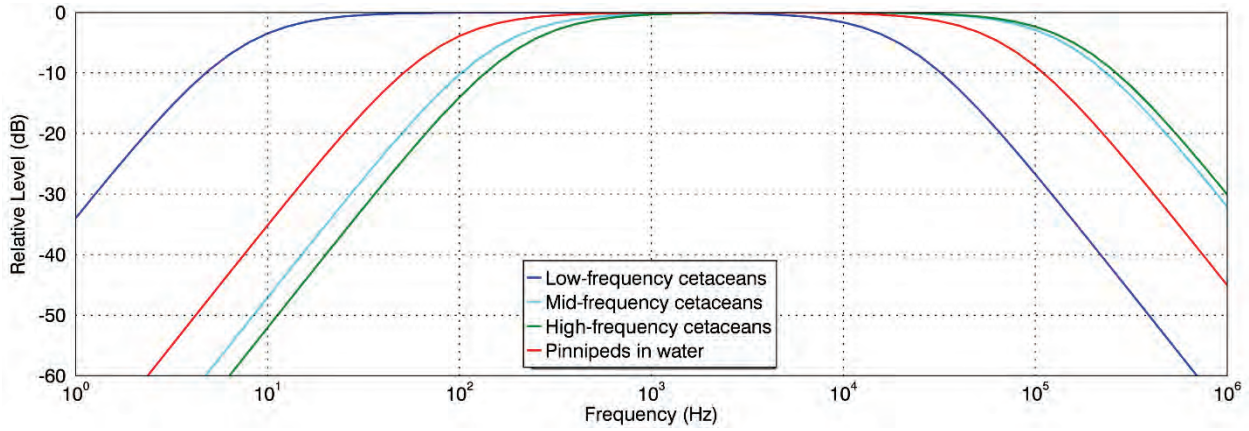

Figure A-3. Auditory weighting functions for functional marine mammal hearing groups as recommended by Southall et al. (2007).

Table A-1. Parameters for the auditory weighting functions recommended by Southall et al. (2007).

Hearing group	Southall et al. (2007)	
	a (Hz)	*b* (Hz)
Low-frequency cetaceans (LFC)	7	22,000
Mid-frequency cetaceans (MFC)	150	160,000
High-frequency cetaceans (HFC)	200	180,000
Pinnipeds in water (Pw)	75	75,000

A.4.2. Finneran 2015

In 2015, a U.S. Navy Technical Report by Finneran (2015) recommended new auditory weighting functions. The overall shape of the auditory weighting functions is similar to human A-weighting functions, which follows the sensitivity of the human ear at low sound levels. The new frequency-weighting function is:

$$G(f) = K + 10\log_{10}\left[\left(\frac{(f/f_{lo})^{2a}}{\left[1+(f/f_{lo})^{2}\right]^{a}\left[1+(f/f_{hi})^{2}\right]^{b}}\right)\right], \quad \text{(A-10)}$$

Although the inclusion of some species changed (e.g., the addition of hourglass (*Lagenorhynchus cruciger*) and Peale's (*Lagenorhynchus australis*) dolphins to the high-frequency functional hearing group), the five recommended functional hearing groups remained those presented in the Finneran and Jenkins (2012). Table A-2 lists the frequency-weighting parameters for each hearing group; Figure A-4 shows the resulting frequency-weighting curves.

Table A-2. Parameters for the auditory weighting functions recommended by Finneran (2015).

Hearing group	*a*	*b*	f_{lo} (Hz)	f_{hi} (kHz)	*K* (dB)
Low-frequency cetaceans	1.5	2	380	13,000	0.43
Mid-frequency cetaceans	1.6	2	7,400	110,000	1.02
High-frequency cetaceans	1.7	2	16,000	150,000	1.63
Phocid pinnipeds in water	2.0	2	770	27,000	0.49
Otariid pinnipeds in water	0.8	2	1,300	37,000	0.38

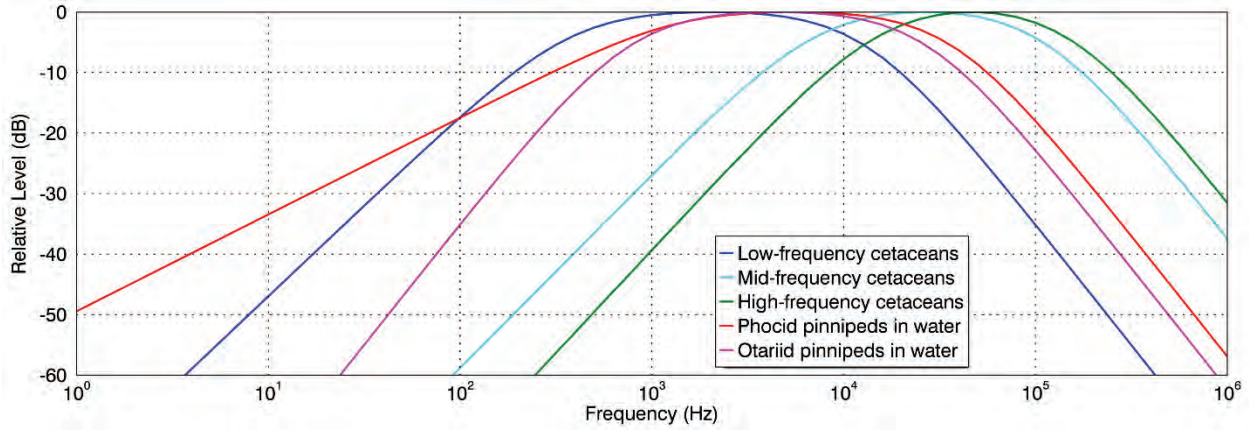

Figure A-4. Auditory weighting functions for functional marine mammal hearing groups as recommended by Finneran (2015).

A.5. Sound Propagation Models

A.5.1. Transmission Loss

The propagation of sound through the environment was modeled by predicting the acoustic transmission loss—a measure, in decibels, of the decrease in sound level between a source and a receiver some distance away. Geometric spreading of acoustic waves is the predominant way by which transmission loss occurs. Transmission loss also happens when the sound is absorbed and scattered by the seawater, and absorbed scattered, and reflected at the water surface and within the seabed. Transmission loss depends on the acoustic properties of the ocean and seabed; its value changes with frequency.

If the acoustic source level (SL), expressed in dB re 1 µPa @ 1 m, and transmission loss (TL), in units of dB, at a given frequency are known, then the received level (RL) at a receiver location can be calculated in dB re 1 µPa @ 1 m by:

$$\mathrm{RL} = \mathrm{SL} - \mathrm{TL} \, . \qquad \text{(A-11)}$$

A.5.2. Acoustic Propagation with MONM

Underwater sound propagation (i.e., transmission loss) at frequencies of 10 Hz to 2 kHz was predicted with JASCO's Marine Operations Noise Model (MONM). MONM computes received per-pulse SEL for directional impulsive sources, and SEL over 1 s for non-impulsive sources, at a specified source depth.

MONM computes acoustic propagation via a wide-angle parabolic equation solution to the acoustic wave equation (Collins 1993) based on a version of the U.S. Naval Research Laboratory's Range-dependent

Acoustic Model (RAM), which has been modified to account for a solid seabed (Zhang and Tindle 1995). The parabolic equation method has been extensively benchmarked and is widely employed in the underwater acoustics community (Collins et al. 1996). MONM accounts for the additional reflection loss at the seabed, which results from partial conversion of incident compressional waves to shear waves at the seabed and sub-bottom interfaces, and it includes wave attenuations in all layers. MONM incorporates the following site-specific environmental properties: a bathymetric grid of the modeled area, underwater sound speed as a function of depth, and a geoacoustic profile based on the overall stratified composition of the seafloor.

MONM computes acoustic fields in three dimensions by modeling transmission loss within two-dimensional (2-D) vertical planes aligned along radials covering a 360° swath from the source, an approach commonly referred to as N×2-D. These vertical radial planes are separated by an angular step size of $\Delta\theta$, yielding N = 360°/$\Delta\theta$ number of planes (Figure A-5).

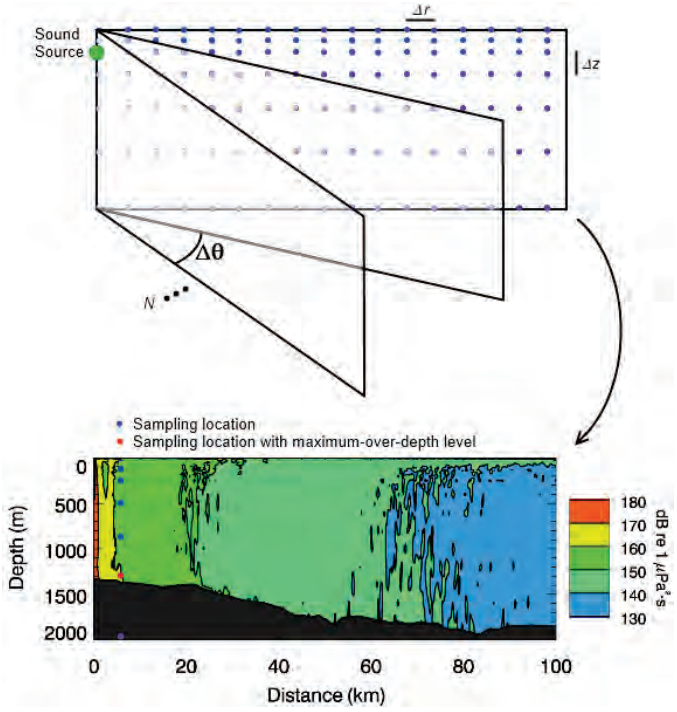

Figure A-5. The N×2-D and maximum-over-depth modeling approach used by MONM.

MONM treats frequency dependence by computing acoustic transmission loss at the center frequencies of 1/3-octave-bands. Sufficiently many 1/3-octave-bands, starting at 10 Hz, are modeled to include the majority of acoustic energy emitted by the source. At each center frequency, the transmission loss is modeled within each of the N vertical planes as a function of depth and range from the source. The 1/3-octave-band received per-pulse SEL are computed by subtracting the band transmission loss values from the directional source level in that frequency band. Composite broadband received SEL are then computed by summing the received 1/3-octave-band levels.

The frequency-dependent transmission loss computed by MONM may be corrected to account for the attenuation of acoustic energy by molecular absorption in seawater. The volumetric sound absorption is quantified by an attenuation coefficient, expressed in units of decibels per kilometer (dB/km). The absorption coefficient depends on the temperature, salinity, and pressure of the water as well as the sound frequency. In general, the absorption coefficient increases with the square of frequency. The absorption of acoustic wave energy has a noticeable effect (>0.05 dB/km) at frequencies above 1 kHz. For example, at 10 kHz the absorption loss over 10 km distance can exceed 10 dB. This coefficient for seawater can be computed according to the formulae of François and Garrison (1982b, b), which

consider the contributions of pure seawater, magnesium sulfate, and boric acid. The formula applies to all oceanic conditions and frequencies from 200 Hz to 1 MHz. For this project, absorption coefficients were computed and applied for all modeled frequencies. Because of the computational expense associated with parabolic equation modeling at frequencies at or above several kHz and the relative importance of absorption at such frequencies, the transmission loss in each frequency band between 6 and 32 kHz was approximated from the transmission loss computed at 5 kHz by applying the correct frequency-dependent absorption coefficient in each band.

The received per-pulse SEL sound field within each vertical radial plane is sampled at various ranges from the source, generally with a fixed radial step size. At each sampling range along the surface, the sound field is sampled at various depths, with the step size between samples increasing with depth below the surface. The step sizes are chosen to provide increased coverage near the depth of the source and at depths of interest in terms of the sound speed profile. For areas with deep water, sampling is not performed at depths beyond those reachable by marine mammals. The received per-pulse SEL at a surface sampling location is taken as the maximum value that occurs over all samples within the water column, i.e., the maximum-over-depth received per-pulse SEL. These maximum-over-depth per-pulse SEL are presented as color contours around the source.

MONM's predictions have been validated against experimental data from several underwater acoustic measurement programs conducted by JASCO (Hannay and Racca 2005, Aerts et al. 2008, Funk et al. 2008, Ireland et al. 2009, O'Neill et al. 2010, Warner et al. 2010, Racca et al. 2012a, Racca et al. 2012b, Martin et al. 2015).

An inherent variability in measured sound levels is caused by temporal variability in the environment and the variability in the signature of repeated acoustic impulses (sample sound source verification results is presented in Figure A-6). While MONM's predictions correspond to the averaged received levels, cautionary estimates of the threshold radii are obtained by shifting the best fit line (solid line, Figure A-6) upward so that the trend line encompasses 90% of all the data (dashed line, Figure A-6).

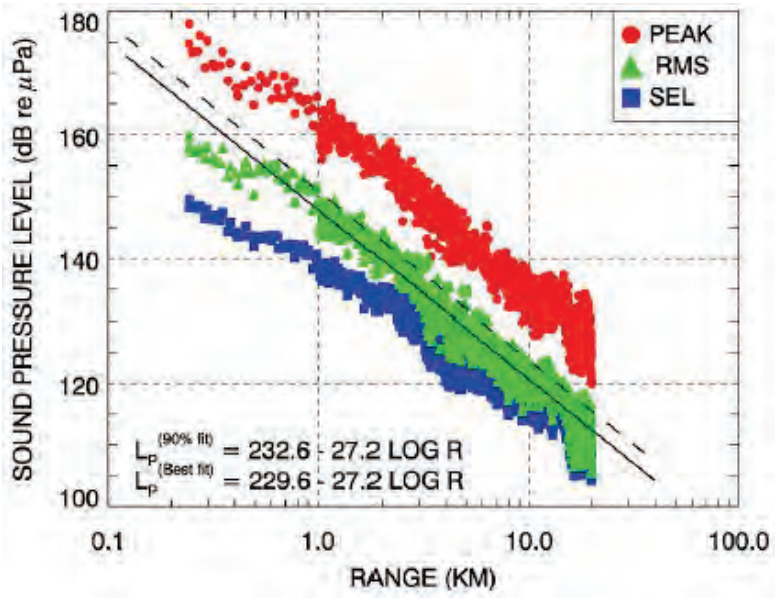

Figure A-6. Peak and SPL and per-pulse SEL versus range from a 20 in^3 air gun array. Solid line is the least squares best fit to SPL. Dashed line is the best fit line increased by 3.0 dB to exceed 90% of all SPL values (90th percentile fit) (Ireland et al. 2009, Figure 10).

Sound source verification results show that this 90th percentile best-fit is, on average, 3 dB higher than the original best fit line for sources in water depths greater than 20 m (Aerts et al. 2008, Funk et al. 2008, Ireland et al. 2009, O'Neill et al. 2010, Warner et al. 2010). Consequently, a safety factor of 3 dB is

customarily added to the predicted received levels to provide cautionary results reflecting the inherent variability of sound levels in the modeled area.

The transmission loss computed by MONM can be further corrected to account for the attenuation of acoustic energy by molecular absorption in seawater. The volumetric sound absorption is quantified by an attenuation coefficient, expressed in units of decibels per kilometer (dB/km). The absorption coefficient depends on the temperature, salinity, and pressure of the water as well as the sound frequency. In general, the absorption coefficient increases with the square of frequency. The absorption of acoustic wave energy has a noticeable effect (>0.05 dB/km) at frequencies above 1 kHz. At 10 kHz, the absorption loss over a 10 km distance can exceed 10 dB. This coefficient for seawater can be computed according to the formulae of François and Garrison (1982b, 1982a), which consider the contribution of pure seawater, magnesium sulfate, and boric acid. The formulae apply to all oceanic conditions and frequencies from 200 Hz to 1 MHz.

A.5.3. Acoustic Propagation with FWRAM

For impulsive sounds, time-domain representations of the pressure waves generated in the water are required to calculate peak pressure level or to accuratly model sound propagating away from a vertical source array. For this study, synthetic pressure waveforms were computed using FWRAM, which is a time-domain acoustic model based on the same wide-angle parabolic equation (PE) algorithm as MONM. FWRAM computes synthetic pressure waveforms versus range and depth for range-varying marine acoustic environments, and it takes the same environmental inputs as MONM (bathymetry, water sound speed profile, and seabed geoacoustic profile). Unlike MONM, FWRAM computes pressure waveforms via Fourier synthesis of the modeled acoustic transfer function in closely spaced frequency bands. FWRAM employs the array starter method to accurately model sound propagation from a spatially distributed source (MacGillivray and Chapman 2012).

Synthetic pressure waveforms were modeled over the frequency range 10–2048 Hz, inside a 1 s window. The synthetic pressure waveforms were post-processed, after applying a travel time correction, to calculate PK and SEL metrics versus range and depth from the sources.

Attention: Mr Patrick Lee

Environmental Baseline Survey and Habitat Assessment Report
Continental Slope AUV Survey
Hammerhead Development, Offshore Guyana

As a subcontractor to Fugro Canada Corp., Fugro GB Marine Limited has the pleasure of submitting the Final Environmental Baseline Survey and Habitat Assessment Report for the integrated site investigation programme within the Hammerhead Development Field, offshore Guyana. This report presents a summary of the survey operations and the results from the environmental survey. This report is based on AUV data collected between 17 March and 18 April 2019 by FUSAMI aboard the R/V Fugro Brasilis.

This work was carried out as authorised by Master Marine Survey Order A4001077, dated 8 November 2018 and under Master Marine Survey Agreement A1998840 and Marine Survey Sub agreement A2002836, both dated 14 February 2006 (contract reference Schedule H – Onshore Reporting, item 8.3). This report was prepared in general accordance with the Esso Exploration and Production Guyana Limited (EEPGL) project work scope, in accordance with Fugro proposal PL18-036 dated 8 June 2018, and as otherwise agreed with the EEPGL representative, Patrick Lee.

We hope that you find this report to your satisfaction; should you have any queries, please do not hesitate to contact us.

Yours faithfully
Fugro GB Marine Limited

EXECUTIVE SUMMARY

Introduction

On the instruction of Esso Exploration and Production Guyana Limited (EEPGL), Fugro performed an integrated site investigation programme within the Hammerhead development, offshore Guyana. Geophysical operations, comprising automated underwater vehicle (AUV), multibeam echosounder (MBES), side scan sonar (SSS), and sub-bottom profiler (SBP) data collection were undertaken during the first phase of survey operations. The second phase of the site investigation comprised over the side mounted (OTSM), MBES and hull-mounted sub-bottom profiler (SBP) data collection upslope of the AUV survey area, geotechnical sampling and an environmental baseline survey (EBS).

Survey Strategy

Seabed video and still photographic data collection was performed at 15 locations to establish and identify the seabed habitats and epifaunal species within the survey area. Sediment box core sampling was performed at eight locations to establish the physico-chemical and biological properties of the sediment. Water quality was assessed through in situ collection of water column profiles and acquisition of water samples at eight locations.

Sediment Characterisation

Using the Wentworth (1922) sediment description, four stations were classified as ‘fine silt’, three stations were classified as ‘very fine silt’ and the remaining station classified as ‘medium silt’. The majority of the sediments were classed as very poorly sorted with one station classified as poorly sorted. All stations had a sediment composition consisting of mainly sand and fines content.

Sediment Hydrocarbons

The gas chromatographic profiles obtained from sediments collected from within the Hammerhead survey area were typical of background sediments, displaying weathered low level petroleum and biogenic hydrocarbons and an associated unresolved complex mixture (UCM) commonly found in marine sediments.

The total 2 to 6 ring polycyclic aromatic hydrocarbon (PAH) concentrations were low across the survey area. The United States Environmental Protection Agency’s 16 priority PAH pollutants (US EPA 16 PAH) were below their respective effects range low (ERL) values at all stations (Buchman, 2008).

Sediment Trace/Heavy Metals

The concentrations of metals (aqua regia digest) displayed low variability for all metal concentrations across the sediments (RSD ≤ 21 %). Metal concentrations were below their respective ERL values at all stations, with the exception of arsenic and nickel. Arsenic concentrations exceeded the National Oceanic and Atmospheric Administration (NOAA) ERL (8.2 µg/g, Buchman, 2008) at six stations, whilst nickel concentrations exceeded the NOAA ERL (20.9 µg/g, Buchman, 2008) at seven stations. No arsenic or nickel concentrations exceeded their respective NOOA ERM (70.0 µg/g and 51.6 µg/g, respectively, Buchman, 2008).

Water Profiles

Water profiles showed a stratified water column, with a defined thermocline, halocline, pH boundary and oxygen boundary down to ca. 400 m, after which values remained relatively constant. Turbidity remained constant throughout the profile.

Water Nutrients and Total Suspended Solids (TSS)

Nitrogen compounds, total organic carbon (TOC) and TSS values across the Hammerhead water samples showed no evidence of stratification.

Water Hydrocarbons

Total hydrocarbon content (THC) concentrations across the survey area were below the MRV for the majority of stations with the exception of station EBSHHW_05 (Bottom) and station EBSHHW_07 (Mid and Bottom). Unresolved complex mixture (UCM) concentrations were below the minimum reporting value (MRV) of 10 µg/L for all stations with the exception of station EBSHHW05 (Bottom). Total 2 to 6 ring PAH concentrations displayed moderate variability (RSD 36 %) between samples. Total US EPA 16 PAH concentrations and naphthalene and phenanthrene/anthracene and dibenzothiophene (NPD) displayed moderate variability (RSD 65 % and 37 % respectively). Percentage NPD displayed low variability (RSD 11 %). The mean total US EPA 16 PAH concentration (3.9 ng/L) within the Hammerhead development was lower than the mean values observed at the Payara development (4.0 ng/L, Fugro, 2019a) and the Liza field survey (9.5 ng/L, Fugro, 2016).

Water Trace/Heavy Metals

Heavy and trace metal concentrations were low in most water samples, being close to or below their respective MRVs in the majority of samples across the Hammerhead development. No metals concentrations exceeded the US EPA criterion continuous concentration (CCC) or criterion maximum concentration (CMC) values (US EPA, 2018). Consequently, the metals concentrations within the water samples are unlikely to negatively impact the benthic or pelagic biota. No trends were observed between metals concentrations and depth in the Hammerhead water samples.

Seabed Habitats

Analysis of the photographic data identified two broad biotope complexes in accordance with the ‘Biotopes/Ecosystems Nomenclature, Habitats of South America’ (Institute of Terrestrial Ecology, 1996) with ‘Sublittoral soft seabeds (11.22) observed at all drop-down video stations and ‘Deep-sea floor” (11.21) observed at all transects.

EUNIS (2012) biotopes were also assigned to offer further habitat description: ‘Sublittoral soft seabeds’ (11.22) were assigned the EUNIS (2012) ‘Sublittoral mud’ (A5.3) habitat. The EUNIS (2012) classification allowed the ‘Deep-sea floor” (11.21) (Institute of Terrestrial Ecology, 1996) description to be further split in to: Muddy Sand’ (A6.4), describing areas with gravelly, muddy sand sediments where epifaunal diversity and abundance was low; and ‘deep-sea rock and artificial hard substrata’ (A6.1) describing areas of elevated, exposed bedrock where the epifaunal community comprised predominantly of sessile taxa. No potentially sensitive habitats or species were identified in the current survey.

Macrofauna

The faunal community within the survey area was moderately diverse with a large number of taxa occurring in relatively low abundances. Arthropods and annelids and were the most numerous taxa recorded, similar to the community recorded at the Payara development (Fugro, 2019a) and Liza field in 2016 (Fugro, 2016).

Univariate analysis indicated that diversity was high across the survey area. Multivariate analysis demonstrated moderate to high variability across the survey area, potentially due to the relatively high number of taxa and the low number of individuals observed. Multivariate statistics highlighted that differences in the macrofaunal community

were largely reflective of elevated abundance of several taxa within shallower stations, and the presence or absence of taxa associated with different depth ranges or depth related parameters (e.g. sediment characteristics).

No meaningful correlations were observed between the macrofaunal community and the physico-chemical parameters sampled across the Hammerhead development survey area.

1. INTRODUCTION

1.1 Background

On the instruction of Esso Exploration and Production Guyana Limited (EEPGL), Fugro performed an integrated site investigation programme in support of the Hammerhead development, offshore Guyana. Automated underwater vehicle (AUV), multibeam echosounder (MBES), side scan sonar (SSS), and sub-bottom profiler (SBP) data collection were undertaken during the first phase of survey operations. The second phase of the site investigation comprised over the side mounted (OTSM), multibeam echosounder (MBES) and hull-mounted SBP data collection upslope of the AUV survey area, geotechnical sampling and an environmental baseline survey (EBS).

The survey was conducted onboard RV Fugro Brasilis during the survey period 22 April to 25 May 2019.

Appendix A outlines the guidelines for use of this report.

1.2 Scope of Work

The surveys were undertaken to establish the water column and sediment conditions encountered at the Hammerhead development. The environmental survey was carried out to assess the biological and physico-chemical properties of the water column and seabed, to acquire sufficient environmental data to describe all habitats recorded within the survey area and to identify and delineate the extent of any potentially sensitive habitats or species. Following the acquisition of the shelf and shelf break geophysical data, camera transects were selected to investigate areas of elevated rough hard substrate which had reduced or near zero signal penetration on the SBP data.

1.3 Coordinate Reference System

All coordinates detailed in this report are referenced to WGS84 (World Geodetic System 1984) datum, Universal Transverse Mercator (UTM) Projection Zone 21 N.

Table 1.1 provides the detailed geodetic and projection parameters.

Table 1.1: Project Geodetic Parameters

Global Positioning System Geodetic Parameters*	
Datum:	World Geodetic System 1984 (WGS84)
Spheroid:	World Geodetic System 1984
Semi major axis:	a = 6 378 137.000 m
Reciprocal flattening:	1/f = 298.257 223 563
Project Projection Parameters	
Grid Projection:	Universal Transverse Mercator (UTM)
UTM Zone:	21 N
Central Meridian:	57° 00’ 00.0” West
Latitude of Origin:	00° 00′ 00″ North
False Easting:	500 000 m
False Northing:	0 m
Scale factor on Central Meridian:	0.9996
Units:	Metre
Notes: * = Fugro Starfix navigation software always uses WGS84 geodetic parameters as a primary datum for any geodetic calculations	

1.4 Regional Standards and Comparable Studies

Regional comparison data was compiled from previous surveys conducted near the study area. The Payara field EBS (Fugro, 2019a) and the Liza field EBS (Fugro, 2016) were conducted at similar water depths to the samples collected in the current survey. The Liza field (Fugro, 2016) metals data are not directly comparable to other regional data due to the application of differing analytical methods and are included for information only.

In the absence of regional standards specific to Guyana for physico-chemical data, internationally recognised environmental standards have been adopted. For results in sediments recorded above the minimum reporting value, comparison has been made to the National Oceanic and Atmospheric Administration (NOAA) effects range low (ERL) and effects range median (ERM) reference values (Buchman, 2008) where applicable. ERLs represent the low point (10th percentile) and ERMs represent the 50th percentile on a continuum of chemical concentrations over which adverse biological effects have been observed (O' Connor, 2004). Water data were compared to the United States Environmental Protection Agency (US EPA) criterion continuous concentration (CCC) and criterion maximum concentration (CMC) values (US EPA, 2018), where available. Detrimental effects are rarely observed in biota when concentrations are below these values.

2. ENVIRONMENTAL SURVEY METHODS

2.1 Survey Strategy

The objectives of the EBS were to provide data to establish the baseline physico-chemical and biological characteristics of the seabed and water column environment, by undertaking water column and seabed sampling. Seabed photographic data were also collected to identify the habitats and epifaunal communities present within the survey area.

The EBS sampling stations were pre-determined by the client. Following the acquisition of the shelf and shelf break geophysical data, camera transects were selected to investigate areas of elevated rough hard substrate which had reduced or near zero signal penetration on the SBP data.

Table 2.1 provides the coordinates, data to be acquired and rationale for each location. The orientation of the camera transects was subject to change to accommodate vessel manoeuvrability at the time of survey operations. Figure 2.1 spatially displays the proposed environmental survey locations overlaid on a SSS mosaic. Figure 2.2 spatially displays the proposed environmental camera transects on bathymetry data, whilst Figure 2.3 spatially displays the proposed drop down camera transects on bathymetry data.

2.2 Survey Methods

Seabed photography was acquired using a Sonar Equipment Services deep-sea camera system mounted within a purpose built camera frame complete with one high resolution video camera, one stills camera, a separate strobe and four light emitting diode lights.

Seabed video footage was displayed on a computer monitor and recorded directly onto a hard drive. A video overlay was used to overlay a navigation string from an attached ultra short baseline (USBL) beacon, including the time, date, depth and location (easting and northing). The survey location and station number were also displayed (manually updated). The stills camera imagery was visible on a second window of the computer. Footage was viewed in real time via a co-axial cable, assisting in the control of the camera in the water. Two lasers were set up 9 cm apart to provide image scaling.

Seabed grab samples were primarily collected for analysis of physico-chemical and biological sediment characterisation; however, observations of the grab sample contents have been used to supplement the seabed video/photographic data in describing the benthic habitat where appropriate. Seabed samples were acquired using a United States Naval Electronics Laboratory (US NEL) 0.25 m^2 box corer equipped with a USBL beacon, within the agreed 50 m sampling accuracy.

Water profiles were acquired from sea surface to near seabed during deployment and recovery of a Valeport 606+ deepwater conductivity temperature depth (CTD) profiler, set up to record depth, salinity, conductivity, dissolved oxygen (DO), pH, turbidity and temperature. At each station, the initial drop had a clump weight, beacon, CTD and two 5 litre Niskin water samplers attached to the lifting wire at intervals coinciding with the sampling depths. The CTD profiles were acquired simultaneously with the collection of near-seabed (bottom) water samples. Mid-depth and near-surface samples were then acquired in two subsequent deployments of the Niskin sampler only.

Further detail can be found within the Hammerhead development field report (Fugro, 2019b).

2.3 Analytical Strategy

The following list briefly describes the suites of analyses carried out. Further description of the methods used for the analyses are detailed in Appendix B.

- Sediment particle size distribution (PSD) analysis and characterisation including total organic carbon (TOC) (Section 4);
- Sediment total hydrocarbon content (THC) by gas chromatography–flame ionisation detection (GC-FID; Sections 5.2.1 and 5.2.2);
- Sediment 2 to 6 ring aromatic hydrocarbons, including the United States Environmental Protection Agency's (US EPA) 16 priority pollutants, by gas chromatography-mass spectrometry (GC-MS; Section 5.2.3);
- Sediment metals predominantly by an aqua regia acid digest and subsequent instrumental analysis. Arsenic, cadmium, chromium, copper, lead, nickel, selenium and zinc were analysed by inductively coupled plasma-mass spectrometry (ICP-MS). Aluminium, barium and iron were analysed by inductively coupled plasma-optical emission spectrometry (ICP-OES). Mercury was analysed by cold vapour-atomic fluorescence spectroscopy (CV-AFS) (Section 6);

- Water sample data were analysed for total suspended solids (TSS), TOC, nitrogen compounds, hydrocarbons and metals content (Section 7);
- Habitats were classified using the 'Biotopes/Ecosystems Nomenclature, Habitats of South America' (Institute of Terrestrial Ecology, 1996); (Section 8)
- Macrofauna were identified and enumerated from two sample replicates at each station, 0.5 mm sieve (Section 9).

3. FIELD OPERATIONS

3.1 Seabed Sampling

Box corer sampling was successfully conducted at all the proposed eight environmental sediment stations. Table 3.1 summarises the samples acquired. Figure 3.1 spatially displays the locations of all completed seabed sampling locations overlaid on a SSS mosaic. Complete suites of samples (two macrofauna, one biodiversity DNA analysis sample and one physico-chemical sample) were acquired at all stations.

Notes:
BSL = Below sea level
FA/FB = Faunal sample A or B
BIO = Biodiversity DNA analysis sample
PC = Physico-chemical sediment sample
* = Mean depth value considered for further statistical analysis

3.2 Seabed Video/Photography

Photographic stills and video data were successfully acquired at all nine proposed drop-down camera stations and at the six proposed camera transects (Table 3.2).

Figure 3.2 spatially displays the locations of all the completed camera transects, whilst Figure 3.3 spatially displays all completed drop down camera transects on bathymetry data. Stations EBSHH_03 and EBSHH_06 were repeated due to technical issues. Acquisition of video and photographic data was successful on the second attempt at station EBSHHDD_05 due to marginal sea conditions affecting vessel manoeuvrability on the first attempt. Poor sea conditions prevented acquisition of good quality stills at station EBSHHDD_01, this station was repeated and on the fourth attempt, stills images were accepted by the onboard client representative.

3.3 Water Sampling and Profiling

A complete suite of water samples was successfully collected at all eight water stations. Two water profiles were collected at all stations except stations EBSHHW_04, EBSHHW_07 and EBSHHW_08. At station EBSHHW_04 the Valeport CTD failed during the first deployment. At station EBSHHW_07 one profile was accepted by the onboard client representative. At station EBSHHW_08 the Valeport CTD failed during the second deployment. Table 3.3 provides details of sample and water profile data acquisition. Figure 3.1 spatially displays the locations of all completed water sampling locations overlaid on a SSS mosaic (along side previously mentioned environmental sampling stations). Water profiles are displayed in Appendix F.

4. SEDIMENT CHARACTERISATION

4.1 Introduction

Sediment samples were analysed for their particle size distribution (PSD) using a combination of two techniques; sieve analysis for all material retained by a 1 mm sieve followed by laser diffraction analysis of the finer material. The results of the particle size analysis (PSA) were treated statistically to characterise the sediment type (Wentworth scale) and particle size homogeneity (sorting).

The proportion of TOC was determined by combustion and non-dispersive infrared detection following inorganic carbon removal.

Relative standard deviation (RSD) indicates the extent of variability in a dataset in relation to the mean value. The RSD value expresses the standard deviation as a percentage of the mean. For the purpose of this report, RSD of less than 30 % will be considered low variability, 30 % to 70 % will be considered moderate variability and more than 70 % will be considered high variability.

Appendix B provides full details of the analytical techniques employed and Appendix D displays the histograms of particle size class summary for each station.

4.2 Results

Table 4.1 summarises the particle size distribution. Median particle size (µm) ranged from 6 µm at two stations to 14 µm at station EBSHH_07, with a mean of 8 µm and moderate interstation variability (RSD 34 %). Mean particle size (µm) ranged from 7 µm at station EBSHH_04 to 19 µm at station EBSHH_07, with a mean of 10 µm and moderate interstation variability (RSD 38 %). Mean particle size (phi) ranged from 5.75 phi at station EBSHH_07 to 7.08 phi at station EBSHH_04, with a mean of 6.61 phi. Mean particle size within the Hammerhead survey area was smaller than that recorded in the Payara development in 2018 (mean 363 µm and 1.87 phi; Fugro, 2019a).

The Wentworth (1922) description classifies sediment by grain size. The Wentworth description, assigned from mean particle size, ranged from very fine silt at two stations, fine silt at five stations to medium silt at station EBSHH_07.

Whilst marine sediments may feature a unimodal symmetrical particle size distribution, they may also feature non-symmetrical or multimodal distributions. For unimodal symmetrical distributions, all central values are equivalent (e.g. mean is equal to median). However, where sediment distributions deviate from this, differences in central values may occur. Sediments across the current survey were broadly unimodal. However, station EBSHH_01 featured a trimodal distribution, whilst stations EBSHH_07 and EBSHH_08 featured a bimodal distribution. Median particle sizes (µm) were broadly similar to mean particles sizes (µm). However, median particle sizes were consistently slightly lower than mean particle sizes across the survey area, with the highest discrepancy reported at station EBSHH_07.

Standard deviation (SD) of particle size indicates the degree of spread of individual size classes about the mean and provides the basis of a sorting index, in which low values indicate sediments to be fairly homogeneous (good sorting) while high values suggest a relatively large scatter of particle sizes about the mean (poor sorting). Standard deviation values ranged from 2.02 at station EBSHH_04 to 2.78 at

station EBSHH_07, with a mean of 2.28. Consequently, all sediments within the survey area were categorised as very poorly sorted.

Skewness indicates the tendency of particle size classes to be skewed about the mean, either towards coarser sediment (negative skewness) or finer sediment (positive skewness). Skewness values ranged from -0.83 at station EBSHH_03 to -0.18 at station EBSHH_07, with a mean value of -0.58. Consequently, all sediments within the survey area were coarse skewed. Mean particle size within the Hammerhead survey area was more coarse skewed than that recorded in the Payara development in 2018 (mean 0.19 phi; Fugro, 2019a).

Table 4.2 summarises the sediment characteristics, including granulometry and organic content (as TOC), across the Hammerhead development survey area. Figure 4.1 presents the physical composition of the sediments at each station, whilst Figure 4.2 presents the fractional composition of the sediments spatially across the survey area.

The sediment composition was broadly similar across the survey area (Table 4.2 and Figure 4.1). Sediments were largely comprised of the fines fraction, which ranged from 67.84 % at station EBSHH_07 to 91.97 % at station EBSHH_04, with a mean of 85.00 % and low interstation variability (RSD 9 %). The proportion of the sand fraction ranged from 8.03 % at station EBSHH_04 to 32.07 % at station EBSHH_07, with a mean of 14.97 % and moderate interstation variability (RSD 53 %). No gravel was present in stations EBSHH_04, EBSHH_06 and EBSHH_08, with the proportion of gravel low (≤ 0.09 %) in all other stations (Table 4.2). The sediment within the Hammerhead survey area comprised a higher proportion of the fines fraction than that recorded in historic datasets, in the Payara development (mean 44.5 %; Fugro, 2019a) and the Liza field in 2016 (mean 60.78 %; Fugro, 2016). Conversely, the sediment within the Hammerhead survey area comprised a lower proportion of the gravel fraction than that recorded in historic datasets in the Payara development (mean 0.12 %; Fugro, 2019a) and the Liza field in 2016 (mean 0.11 %; Fugro, 2016).

The Folk descriptions classify sediment by the relative proportion of sediment fractions. The Folk description (BGS modified), assigned from the relative proportion of the gravel, sand and fines fractions, classified all sediment sampled in the survey area as sandy mud, with the exception of stations EBSHH_04 and EBSHH_05, which were classified as mud.

The TOC content ranged from 0.53 % at station EBSHH_03 to 0.74 % at stations EBSHH_01 and EBSHH_08, with a mean of 0.64 % and low interstation variability (RSD 9 %). The mean TOC content reported within the current survey was higher than that recorded in historic datasets in the Payara development (mean 0.31 %; Fugro, 2019a) and the Liza field in 2016 (mean 0.32 %; Fugro, 2016).

Table 4.1: Summary of Particle Size Distribution, Hammerhead Development

Station	Modality	Median [µm]*	Mean [µm]*	Mean [phi]*	Wentworth Description†	SD [phi]*	Sorting Index‡	Skewness [phi]*

5. SEDIMENT HYDROCARBONS

5.1 Introduction

The sediment samples were analysed for hydrocarbon content including THC, total n-alkanes (nC_{12} to nC_{36}) and PAHs, specifically the United States Environmental Protection Agency's 16 priority PAH pollutants (US EPA 16 PAHs) and alkylated PAHs.

Samples were extracted by ultrasonication of wet sediments with mixed solvents. The sample extracts were then cleaned up using absorption column chromatography. The extracts were analysed for THC, unresolved complex mixture (UCM), individual and total n-alkanes (nC_{12} to nC_{36}) and the subsequent carbon preference index (CPI) using GC-FID. Aromatic hydrocarbons were analysed by GC-MS.

The total hydrocarbon material present was quantified using response factors calculated from the analysis of mixed oil standard solutions over an appropriate range. The UCM was determined by subtracting the area of all the resolved peaks from the total hydrocarbon area and applying the total hydrocarbon response factor. The concentration of individual n-alkanes present in the sediments was determined by measuring the response of each component (nC_{12} to nC_{36}) by GC-FID. Standard solutions containing an appropriate range and concentration of n alkanes were run to calibrate the instrument and to acquire response factors for quantification purposes. Individual n-alkanes were quantified using a series of internal standards. A total n-alkane (nC_{12} to nC_{36}) value for each sediment sample was calculated by summing the concentrations of individual n-alkanes.

The distributions and concentrations of 2 to 6 ring PAHs within the samples were determined by GC-MS. Standard solutions containing an appropriate range and concentration of aromatic hydrocarbons were run to calibrate the instrument and acquire response factors for quantification purposes. Individual aromatic compounds were quantified using a series of deuterated internal standards. The total 2 to 6 ring PAH values for each sediment sample was calculated by summing the concentrations of individual aromatic compounds.

Appendix B provides full details of the analytical techniques employed.

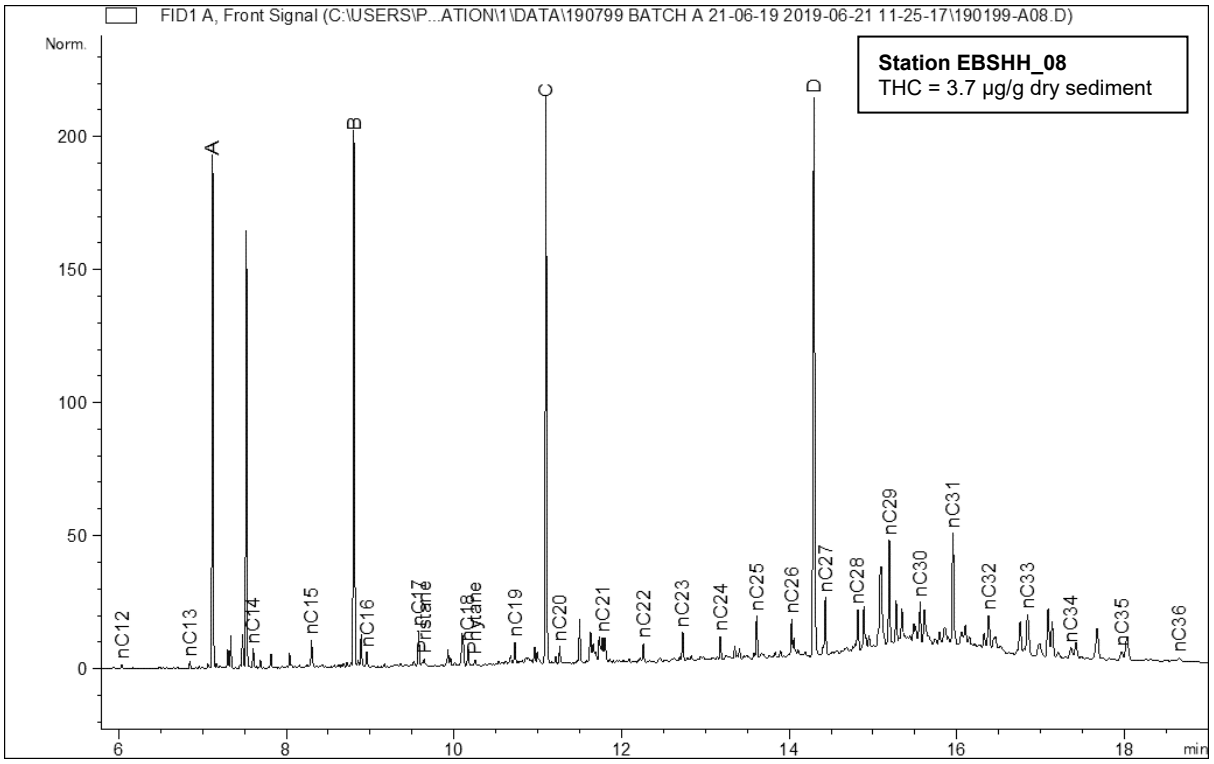
5.2 Results

5.2.1 Gas Chromatography–Flame Ionisation Detection (GC-FID) Hydrocarbon Profiles

A visual comparison of the GC-FID profiles can provide information on the potential origins of the hydrocarbons present in marine sediments samples. The GC-FID profiles illustrating the hydrocarbon components detected in each of the sediment samples are provided in Appendix E1 to support more detailed discussions (Section 10.3) relating to the hydrocarbon components identified by GC-FID analysis of the sediments. Figure 5.1 displays an example gas chromatogram, representative of the grab samples across the Hammerhead development survey area.

The GC-FID profiles obtained for all the sediment samples were broadly similar. The example chromatogram in Figure 5.1 is characterised by a small 'hump' of unresolved material peaking late in the chromatogram window and a homologous series of trace level resolved n-alkanes. The slight prevalence of the heavier odd number n-alkanes (nC_{27}, nC_{29}, nC_{31}), indicates trace inputs of biogenic material from terrestrial run-off. The peak present prior to nC_{14}, pronounced at stations EBSHH_01,

EBSHH_02, EBSHH_04, EBSHH_05 and EBSHH_08 is potentially a biogenic signature from the survey area. The GC-FID profiles for the Hammerhead sediments are all characteristic of background sediments.



Notes:
THC = Total hydrocarbon content
A, B, C and D peaks refer to the internal standards added for quantification

Figure 5.1: Gas chromatographic profile for typical surface sediment (station EBSHH_08), Hammerhead development

5.2.2 Total Hydrocarbon and n-Alkanes (nC_{12} to nC_{36}) Content

Table 5.1 presents the concentrations of total hydrocarbons, UCM, total n-alkanes and CPI ratios (nC_{12} to nC_{36}) and pristane/phytane ratios reported from the surface sediment across the Hammerhead development survey area. Appendix E.2 presents individual n-alkane concentrations for the sediments analysed across the Hammerhead development survey area. Table 5.1 also includes hydrocarbon data reported from neighbouring locations (e.g. the Liza field in 2016 (Fugro, 2016) and the Payara development in 2018 (Fugro, 2019a)). Note that the data from the Liza field is not directly comparable as it is over the nC_{10} to nC_{40} range and so is included for information only.

Total hydrocarbon content (THC) reported for the survey area ranged from 2.0 µg/g at station EBSHH_07 to 3.7 µg/g at station EBSHH_08, with low interstation variation (RSD 22%) and a mean of 2.61 µg/g. The mean THC concentrations observed at the Payara development (0.7 µg/g; Fugro, 2019a) were lower than that observed at the Hammerhead development.

Unresolved complex mixture (UCM) reported for the survey area ranged from 1.0 µg/g at stations EBSHH_01 and EBSHH_07 to 1.9 µg/g at station EBSHH_08, with a mean concentration

of 1.28 µg/g. Variation across all stations was low (RSD 25 %). The mean UCM (1.28 µg/g) was higher at the Hammerhead development in comparison to the mean UCM concentrations recorded in the historic survey at the Payara development (0.4 µg/g; Fugro, 2019a).

The total n-alkane (nC_{12} to nC_{36}) concentration ranged from 0.15 µg/g at station EBSHH_07 to 0.32 µg/g at station EBSHH_07, with a mean concentration of 0.25 µg/g. Variation across all stations was low (RSD 20 %). Mean concentrations recorded at the Payara development (0.08 µg/g; Fugro, 2019a) were lower than those at the Hammerhead development.

The CPI ratio for the nC_{12} to nC_{36} n-alkanes ranged from 1.81 at station EBSHH_08 to 2.13 at station EBSHH_07 with a mean value of 1.95 and low interstation variability (RSD 5 %). The mean CPI value recorded at the Payara development (2.22; Fugro, 2019a) was broadly comparable to those observed at the Hammerhead development.

The pristane/phytane (Pr/Ph) ratios ranged from 0.92 at station EBSHH_02 to 1.58 at station EBSHH_03, with a mean value of 1.25 and low variation (RSD 18 %). The mean Pr/Ph ratio recorded at the Payara development (2.42; Fugro, 2019a) was higher than that observed at the Hammerhead development.

5.2.3 Sediment Aromatic Hydrocarbon Content

The distribution and concentration of aromatic compounds in seabed sediments were analysed by GC-MS. The aromatic compounds quantified were the naphthalenes (2 ring aromatics), 3 to 6 ring PAHs and the dibenzothiophenes (sulphur containing heteroaromatics). Table 5.2 summarises the total concentrations of aromatic hydrocarbons, including the US EPA 16 PAH and naphthalenes, phenanthrenes and dibenzothiophenes (NPD).

Appendix E.3 presents the individual aromatic hydrocarbons and their alkyl homologue concentrations across the Hammerhead development survey area, with the US EPA 16 PAH concentrations presented in Appendix E.3 including reference values where available. The distributions of aromatic hydrocarbons are displayed as three-dimensional plots for ease of interpretation in Appendix E.4.

Total 2 to 6 ring PAH concentrations ranged from 0.034 µg/g at station EBSHH_07 to 0.064 µg/g at station EBSHH_08, with a mean concentration of 0.047 µg/g and low interstation variation (RSD 24 %). The mean total 2 to 6 ring PAH concentration was above the mean observed at the Payara development (0.004 µg/g; Fugro 2019a) while the mean total 2 to 6 ring PAH concentration observed at the Liza field (0.048 µg/g; Fugro 2016) was comparable. The total 2 to 6 ring PAH concentrations at all stations were below the NOAA ERL and ERM values (Buchman, 2008).

Total US EPA 16 PAH concentrations ranged from 2.4 µg/g (station EBSHH_07) to 7.5 µg/g (station EBSHH_08) with a mean of 5.1 µg/g and displayed moderate interstation variation (RSD 33%). The mean concentration exceeded the Payara development mean (0.004 µg/g; Fugro 2019).

The proportion of petrogenically derived NPD to total 2 to 6 ring PAH material ranged from 14 % (station EBSHH_08) to 23 % (station EBSHH_01) with a mean of 19 % and low interstation variability (RSD 17 %).

Figure 5.2 displays the concentrations of total 2 to 6 ring PAHs in relation to THC values across the Hammerhead development survey area. In general, there is a correlation between THC and PAH content, indicating that increased sediment PAH concentrations are typically related to an increase in total hydrocarbons.

Table 5.2: Summary of Sediment Hydrocarbon Analysis, Hammerhead Development

6. SEDIMENT METALS

6.1 Introduction

Sediments collected from the Hammerhead development survey area were analysed for selected elements: aluminium, arsenic, barium, cadmium, chromium, copper, iron, lead, mercury, nickel, selenium and zinc using ICP-MS and ICP-OES.

The sediment samples were analysed using an aqua regia digest technique. This provides a strong partial digest, releasing into solution metals associated with the fines fraction within the sediments (but does not extract all trace elements associated with the coarse fraction). As macrofaunal communities can exhibit a preference for finer sediments, the concentrations of metals released by an aqua regia digest are typically considered indicative of those influencing biological interactions.

The sediment samples underwent an aqua regia digest followed by multi-element analysis by inductively coupled plasma-mass spectrometry (ICP-MS) or by inductively coupled plasma-optical emission spectrometry (ICP-OES). These methods were used to analyse aluminium, arsenic, barium, cadmium, chromium, copper, iron, lead, nickel, selenium and zinc. Analysis of mercury was by cold vapour-atomic fluorescence spectroscopy (CV-AFS). Appendix B provides full details of the analytical techniques employed.

6.2 Results

Table 6.1 summarises the concentrations of the extractable metals in the sediment samples from an aqua regia digest. Table 6.1 also includes metals concentrations reported in neighbouring locations (e.g. the Liza field in 2016 (Fugro, 2016) and the Payara development in 2018 (Fugro, 2019a)). Sediments sampled in the Liza field were subjected to a hydrofluoric acid digest, a total digest, which releases all metals from the sediment, including those bound within the sediment alumino-silicate matrix and typically not biologically available. Consequently, the dataset from the Liza field is not directly comparable and is included for information only. Metals concentrations reported within the Payara development were from an aqua regia digest and comparisons will be made to this dataset throughout the remainder of this section.

Figure 6.1 summarises the concentrations of the extractable metals in the sediment samples following normalisation by aluminium.

All metals concentrations exhibited low interstation variability across the survey area (RSD ≤ 21 %; Table 6.1).

Arsenic concentrations ranged from 5.8 µg/g at station EBSHH_07 to 11 µg/g at station EBSHH_02, with a mean of 8.9 µg/g (Table 6.1). Arsenic concentrations exceeded the NOAA ERL (8.2 µg/g; Buchman, 2008) at all stations, except stations EBSHH_07 and EBSHH_08. No arsenic concentrations exceeded the NOOA ERM (70.0 µg/g, Buchman, 2008). Mean arsenic concentrations reported within the current survey were less than those reported within the Payara development in 2018 (mean 37.8 µg/g). However, the relatively elevated mean arsenic concentration reported in 2018 was largely due to one high result, with arsenic concentrations reported within the current survey broadly comparable to the majority of arsenic concentrations reported within the Payara development in 2018 (Fugro, 2019a).

Cadmium concentrations ranged from 0.11 µg/g at station EBSHH_08 to 0.17 µg/g at station EBSHH_06, with a mean of 0.14 µg/g. No cadmium concentrations exceeded the NOOA ERL (1.20 µg/g; Buchman, 2008). Cadmium concentrations reported within the Payara development in 2018 were all less than the minimum reporting value (MRV) of < 0.2 µg/g (Fugro, 2019a).

Chromium concentrations ranged from 37 µg/g at station EBSHH_07 to 57 µg/g at station EBSHH_02, with a mean of 50 µg/g. No chromium concentrations exceeded the NOOA ERL (81.0 µg/g; Buchman, 2008). Chromium concentrations reported within the current survey were generally higher than those reported within the Payara development in 2018 (mean 30.3 µg/g; Fugro, 2019a).

Copper concentrations ranged from 11 µg/g at station EBSHH_07 to 20 µg/g at station EBSHH_02, with a mean of 17 µg/g. No copper concentrations exceeded the NOOA ERL (34.0 µg/g; Buchman, 2008). Copper concentrations reported within the current survey were broadly comparable to those reported within the Payara development in 2018 (mean 15.1 µg/g; Fugro, 2019a).

Mercury concentrations ranged from 0.025 µg/g at station EBSHH_07 to 0.043 µg/g at stations EBSHH_02 and EBSHH_04, with a mean of 0.038 µg/g. No mercury concentrations exceeded the NOOA ERL (0.150 µg/g; Buchman, 2008). Mercury concentrations reported within the current survey were generally slightly higher than those reported within the Payara development in 2018 (mean 0.0236 µg/g; Fugro, 2019a).

Nickel concentrations ranged from 20 µg/g at station EBSHH_07 to 39 µg/g at station EBSHH_03, with a mean of 33 µg/g. Nickel concentrations exceeded the NOAA ERL (20.9 µg/g; Buchman, 2008) at all stations, except station EBSHH_07. No nickel concentrations exceeded the NOOA ERM (51.6 µg/g; Buchman, 2008). Nickel concentrations reported within the current survey were generally higher than those reported within the Payara development in 2018 (mean 20.0 µg/g; Fugro, 2019a).

Lead concentrations ranged from 14 µg/g at station EBSHH_07 to 22 µg/g at station EBSHH_02, with a mean of 19 µg/g. No lead concentrations exceeded the NOOA ERL (46.7 µg/g; Buchman, 2008). Lead concentrations reported within the current survey were generally higher than those reported within the Payara development in 2018 (mean 12.3 µg/g; Fugro, 2019a).

Zinc concentrations ranged from 61 µg/g at station EBSHH_07 to 97 µg/g at station EBSHH_02, with a mean of 85 µg/g. No zinc concentrations exceeded the NOOA ERL (150 µg/g; Buchman, 2008). Mean zinc concentrations reported within the current survey were generally higher than those reported within the Payara development in 2018 (mean 60.5 µg/g; Fugro, 2019a).

The overall trend in individual metals concentrations is presented in Figure 6.1 and is assessed by comparing the maximum normalised elemental concentrations. Normalising the elemental data for the sediment samples to the highest concentration for each element highlights that station EBSHH_02 generally features the highest metals concentrations across the survey area, whilst station EBSHH_07 generally features the lowest metals concentrations.

Table 6.1: Summary of Sediment Metals Analysis, Hammerhead Development

7. WATER SAMPLES

7.1 Introduction

Water column profiles were acquired at a total of eight stations in the Hammerhead development area. Profiles were acquired from both deployment and recovery from sea surface to near seabed using a Valeport Midas+ deepwater conductivity temperature depth (CTD) profiler recording depth, salinity, dissolved oxygen (DO), pH, turbidity and temperature. Two profiles were acquired at all stations resulting in two downward and two upward datasets; with the exception of stations EBSHHW_04, EBSHHW_07 and EBSHHW_08, where due to equipment malfunction, one profile was acquired at each station.

Seawater samples were collected at the eight sampling stations for the analysis of key indicators of water quality. Discrete water samples were collected at three depths; the surface (10 m), below the thermocline and 20 m above the seabed. Subsamples were analysed for TSS, TOC, nitrogen compounds, hydrocarbon content and metals content.

Full details of methodologies are found in Appendix B.

7.2 Water Profiles

7.2.1 Results

Figure 7.1 presents an example water column profile (EBSHHW_01) displaying temperature, salinity, conductivity, turbidity, dissolved oxygen saturation and pH. Results from all stations showed a stratified water column, with a defined thermocline, halocline, pH boundary and oxygen boundary, below which these parameters notably dropped. Turbidity returned similar values throughout the water column. The full set of results are presented in Appendix F.

7.2.1.1 Temperature

Temperatures across the survey area ranged from 5.0°C to 27.9°C, with a mean of 10.6°C. The largest intrastation variability was reported at station EBSHHW_01 where temperatures of 5.0°C were recorded near the seabed and 27.8°C near the surface, with a temperature range of 22.8°C. Intrastation variability ranged from 54 % to 66 %. A surface temperature of ca. 28 C was recorded from the surface and decreased to ca. 10°C by ca. 400 m at all stations.

7.2.1.2 Salinity

Salinity ranged from 34.4 practical salinity units (PSU) to 36.9 PSU, with a mean of 35.0 PSU. Intrastation variability ranged from 1 % to 2 %. A distinct halocline was observed to a depth of ca. 200 m, where after salinity remained constant at ca. 35.0 PSU at all stations for the remainder of the water profile.

7.2.1.3 Conductivity

Conductivity ranged from 33.5 mS/cm to 57.6 mS/cm, with a mean value of 39.2 mS/cm. Intrastation variability was similar across the survey area, ranging from 16 % to 20 %. Values were ca. 57 mS/cm at surface level and decreased to ca. 35 mS/cm at approximately 400 m for all stations. A gradual decline from 35 mS/cm at 400 m to ca. 34 mS/cm at the lowest recorded depths in the profile was observed for all stations.

7.2.1.4 Turbidity

Turbidity data have been manually de-spiked to remove anomalously high values, interpreted to be caused by floating matter passing in close proximity to the turbidity sensor. These high values are not considered representative of water column conditions within the survey area and were excluded to prevent skewing of the turbidity statistics presented. Turbidity values ranged from 0.513 formazin turbidity units (FTU) to 2.54 FTU across the survey area, with a mean value of 1.70 FTU. Turbidity values remained relatively constant throughout the water column.

7.2.1.5 Dissolved Oxygen (DO)

Dissolved oxygen (DO) saturation ranged from 33.4 % to 108 %, with a mean of 46.9 %. Intrastation variability ranged from 28 % to 45 %. Dissolved oxygen saturations of ca. 108 % were recorded at the surface, decreasing to ca. 40 % by approximately 300 m at all stations. Concentrations then remained relatively constant to a depth of ca. 800 m, where a slight increase was observed for the remainder of the profile.

7.2.1.6 pH

The pH values were alkaline throughout the Hammerhead survey area and ranged from 7.75 to 8.28, with a mean of 7.33. Intrastation variation was low (RSD ca. 1 %). pH values of ca. 8.3 were recorded at the surface to depths and decreased to ca. 7.8 by 200 m.

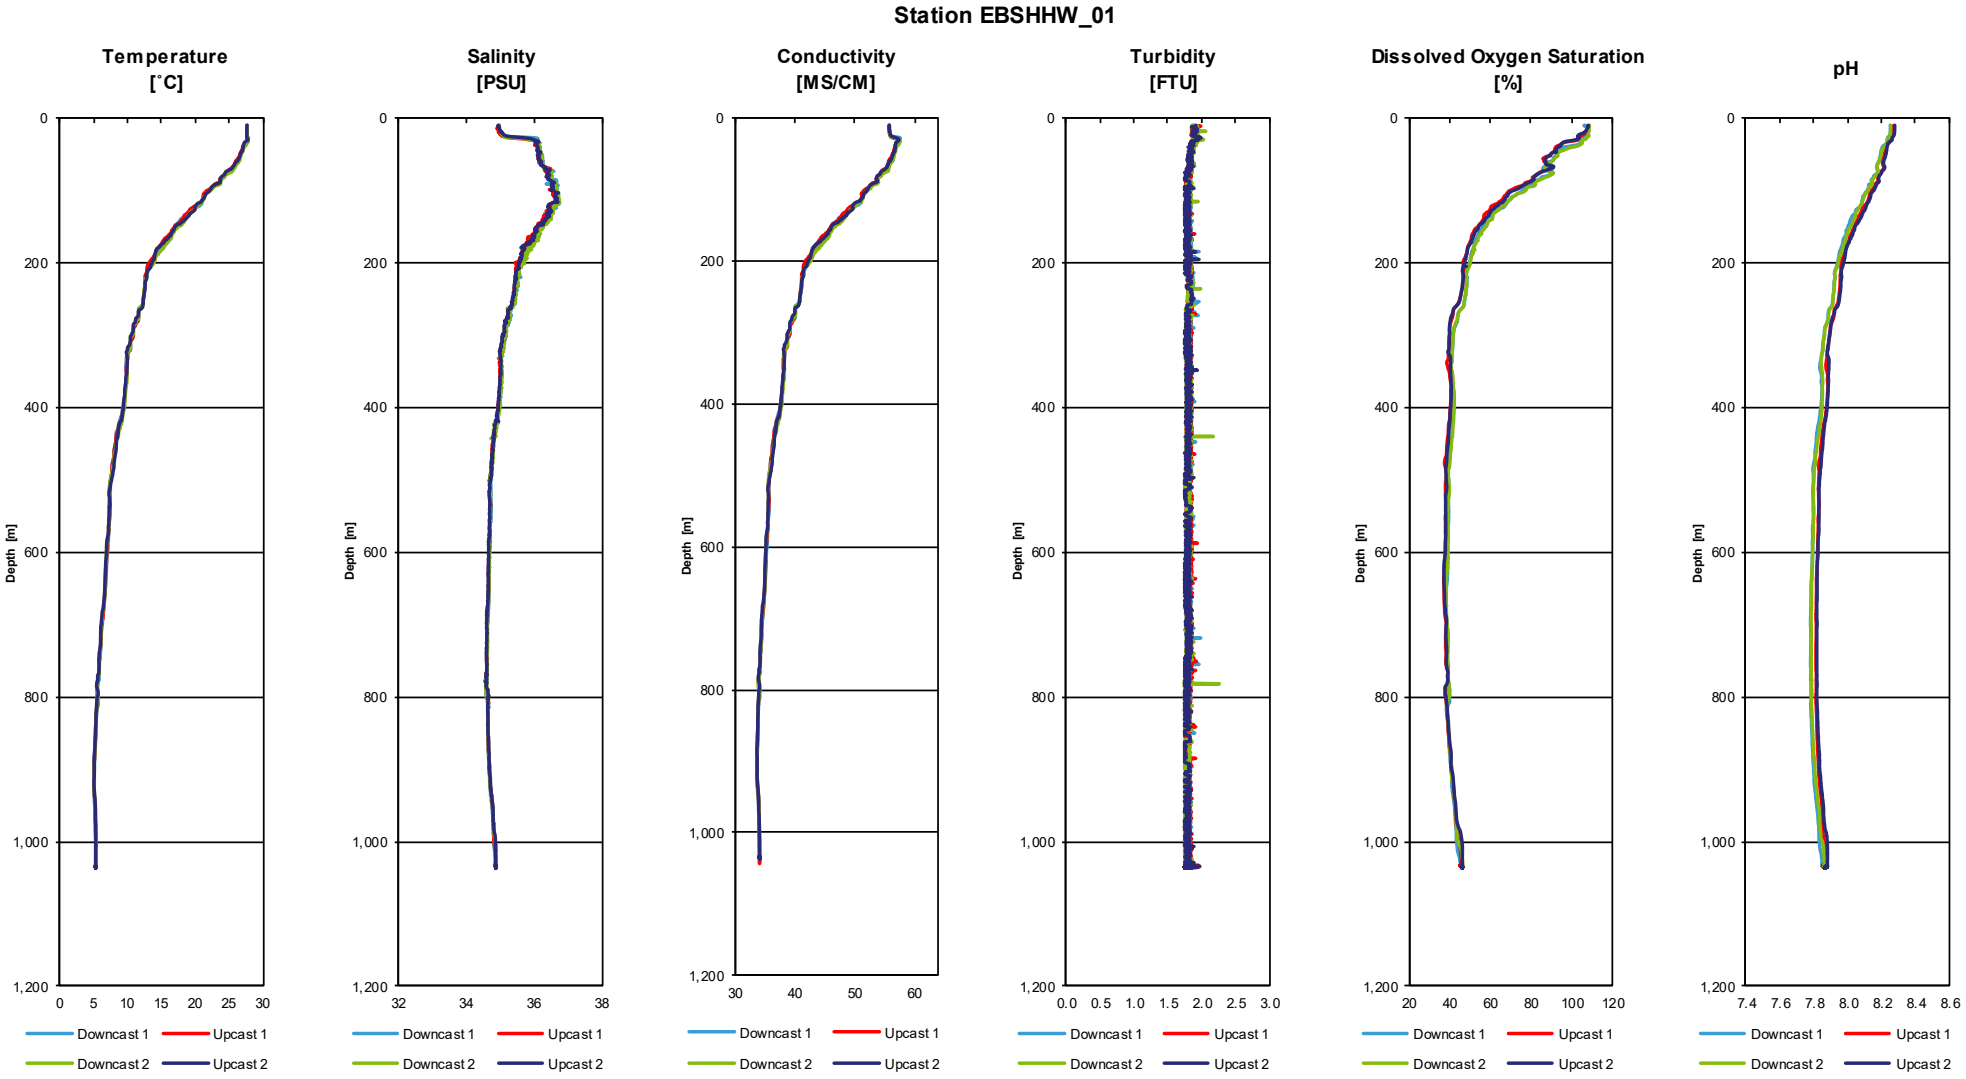

Figure 7.1: Water column profile at sampling station EBSHHW01, Hammerhead development

7.3 Nutrients and Total Suspended Solids (TSS)

7.3.1 Introduction

Water samples from the Hammerhead survey area were analysed by Kaizen LAB for key indicators of water quality including ammoniacal nitrogen, nitrate, nitrite and total Kjeldahl nitrogen (TKN) concentrations and TOC and TSS content, with results displayed in Tables 7.1 and 7.2.

7.3.2 Results

Nitrite and TKN concentrations were below their MRVs (< 0.01 mg/L and < 2.00 mg/L, respectively) at all depths at all stations sampled within the Hammerhead survey area (Table 7.1).

Mean ammoniacal nitrogen concentrations provided little evidence of stratification and were comparable at each sampled depth. In surface seawater samples, ammoniacal nitrogen concentrations ranged from 1.57 mg/L at stations EBSHHW_01 and EBSHHW_04 to 7.62 mg/L at station EBSHHW_05. In mid depth samples, concentrations ranged from 1.34 mg/L at stations EBSHHW_02 and EBSHHW_03 to 4.93 mg/L at station EBSHHW_01. In the bottom depth samples, concentrations ranged from 1.57 mg/L at station EBSHHW_04 to 3.36 mg/L at station EBSHHW_06. Interstation sample variability ranged from low to moderate (RSD 23 % to 61 %). The moderate RSD values observed at surface (61 %) and mid depth (43 %) are largely the result of the relatively high ammoniacal nitrogen concentrations observed at the surface of station EBSHHW_05 (7.62 mg/L) and mid depth of station EBSHHW_01 (4.93 mg/L) (Table 7.1).

Mean nitrate concentrations provided little evidence of stratification and were comparable at each sampled depth. In surface seawater samples, nitrate concentrations ranged from 0.50 mg/L at station EBSHHW_05 to 2.30 mg/L at station EBSHHW_01. In mid depth samples, concentrations ranged from 0.90 mg/L at station EBSHHW_03 to 2.40 mg/L at station EBSHHW_05. In the bottom depth samples, concentrations ranged from 1.90 mg/L at station EBSHHW_01 to 4.20 mg/L at station EBSHHW_03. Interstation sample variability ranged from low to moderate (RSD 26 % to 34 %). Moderate RSD values observed at surface (34 %) and mid depth (30 %) are largely the result of the relatively low nitrate concentrations observed at the surface of station EBSHHW_05 (0.50 mg/L) and mid depth of station EBSHHW_03 (0.9 mg/L) (Table 7.1).

The TSS values across the Hammerhead development water samples showed little evidence of stratification as the mean TSS values for each depth profile were comparable. In surface seawater samples, TSS ranged from 25.6 mg/L at station EBSHHW_05 to 56.4 mg/L at station EBSHHW_03. In mid depth samples, concentrations ranged from 34.4 mg/L at station EBSHHW_02 to 92.4 mg/L at station EBSHHW_07. In the bottom depth samples, TSS concentrations ranged from 42.4 mg/L at station EBSHHW_08 to 108 mg/L at station EBSHHW_06. Interstation sample variability ranged from low to moderate (RSD 21 % to 35 %). Moderate RSD values observed at mid (33 %) and bottom (35 %) are a result of the high TSS values observed at station EBSHHW_07 Mid (92.4 mg/L) and station EBSHHW_06 Bottom (108 mg/L) (Table 7.2). The mean TSS values in the current survey were higher than those from the Payara development (Fugro, 2019a) and the Liza field survey (Fugro, 2016) at comparable depths.

The mean TOC values observed for each depth at the Hammerhead development were comparable suggesting no evidence of stratification. Surface depth values ranged from 1.16 mg/L (EBSHHW_07) to

2.16 mg/L (EBSHHW_03). Mid depth values ranged from 1.02 mg/L (EBSHHW_04) to 1.44 mg/L (EBSHHW_08). Bottom depth values ranged from 0.93 mg/L (EBSHH_08) to 1.33 mg/L (EBSHHW_05) (Table 7.2).

The mean TOC values observed were higher than those observed at the Payara development (Fugro, 2019a) but lower than the mean values recorded at the Liza field survey (Fugro, 2016) at comparable depths.

Table 7.1: Summary of Water Column Nitrogen Compound Concentrations, Hammerhead Development

Station	Ammoniacal Nitrogen [mg/L]			Nitrate [mg/L]			Nitrite [mg/L]			Total Kjeldhal Nitrogen [mg/L]

7.4 Hydrocarbons

7.4.1 Introduction

The water column samples were analysed for hydrocarbon content including THC, total n-alkanes (nC_{12} to nC_{36}) and PAHs, specifically the US EPA 16 PAHs and alkylated PAHs. Total hydrocarbon analysis is displayed in Table 7.3 and PAH content of water samples in Table 7.4.

7.4.2 Results

7.4.2.1 Total Hydrocarbon Content (THC)

The THC concentrations were below the MRV of 10 µg/L at the majority of stations, with the exception of samples EBSHHW_05 (Bottom) (25.3 µg/L) and EBSHHW_07 (Mid and Bottom) (12.2 µg/L and 11.0 µg/L respectively), where concentrations were broadly comparable with the mean of the Liza field survey (16.2 µg/L; Fugro, 2016).

The UCM concentrations were below the MRV of 10 µg/L from all sampled depths at all stations with the exception of sample EBSHHW_05 (Bottom), which had a concentration of 13.8 µg/L. This value was

higher than the mean values observed at the Payara development (3.0 µg/L; Fugro, 2019a) and the Liza field survey (8.9 µg/L; Fugro, 2016).

Total n-alkane concentrations (nC_{12-36}) ranged from 0.19 µg/L in samples EBSHHW_03 (Mid) and EBSHHW_02 (Bottom) to 2.75 µg/L in sample EBSHHW_05 (Bottom). Intrastation variability was high (RSD 112 %), likely due to the high total n-alkane concentration observed in sample EBSHHW_05 (Bottom) (2.75 µg/L). The mean total n-alkane concentration observed at the Hammerhead development (0.46 µg/L) was broadly comparable to the mean observed at the Payara development (0.48 µg/L; Fugro, 2019a). The mean total n-alkane concentration recorded at the Liza field survey (Fugro, 2016) was 2.09 µg/L, considerably higher than the 0.46 µg/L observed at the Hammerhead development.

There was no clear spatial trend in concentrations of THC, UCM or n-alkanes across the survey area and no clear relationship between concentrations of these analytes and depth.

The CPI ratio (nC_{12-36}) displayed low intrastation variation (RSD 11%), with values ranging from 0.78 in sample EBSHHW_08 (Surface) to 1.23 in sample EBSHHW_02 (Surface). The mean CPI ratio (nC_{12-36}) observed at the Hammerhead development (0.97) was lower than that observed at Payara development (1.86; Fugro, 2019a). The mean CPI ratio (nC_{12-36}) observed at the Liza field was 0.94 (Fugro, 2016), comparable to that observed during the current survey.

The pristane to phytane ratio displayed moderate variation (RSD 38%), with values ranging from 0.54 in sample EBSHHW_01 (Bottom) to 4.66 in sample EBSHHW_02 (Surface). The mean pristane to phytane ratio (2.21) observed at the Hammerhead development was comparable to the mean value recorded at the Payara development (2.18; Fugro, 2019a). The mean pristane to phytane ratio recorded at the Liza field (1.33; Fugro, 2016) was lower than that recorded at the Hammerhead development.

7.4.2.2 Polycyclic Aromatic Hydrocarbons (PAHs)

Total 2 to 6 ring PAH concentrations displayed moderate variability (RSD 36 %) between samples, ranging from 0.028 µg/L in sample EBSHHW_08 (Mid) to 0.096 µg/L in sample EBSHHW_05 (Bottom). The mean total 2 to 6 ring PAH concentration for the current survey (0.037 µg/L), was lower than the mean values observed at the Payara development (0.076 µg/L; Fugro, 2019a), and the Liza field survey (0.075 µg/L; Fugro, 2016).

Total US EPA 16 PAH concentrations displayed a moderate variability (RSD 65 %), largely due to the high concentration (15.3 µg/L) recorded in sample EBSHHW_05 (Bottom).

Total NPD displayed moderate variability (RSD 37 %) with values ranging from 0.010 µg/L in sample EBSHHW_02 (Mid) to 0.038 µg/L in sample EBSHHW_05 (Bottom). Percentage NPD displayed low variability (RSD 13 %) with values ranging from 28 % in sample EBSHHW_01 (Mid) to 47 % in sample EBSHHW_05 (Mid).

7.5 Metals

7.5.1 Introduction

Water column samples collected from the Hammerhead survey area were analysed for selected elements: aluminium, arsenic, barium, cadmium, chromium, copper, iron, lead, mercury, nickel, selenium, and zinc using ICP-MS and ICP-OES. Sample analysis was conducted by Kaizen LAB.

Concentrations of metals in the water samples were compared to their respective US EPA criterion continuous concentration (CCC) and criterion maximum concentration (CMC) values (US EPA, 2018). Concentrations below these values are considered concentrations at which detrimental effects are rarely observed in biota.

7.5.2 Results

Table 7.5 summarises the concentrations of metals in the water samples. Table 7.5 also includes metals concentrations reported in neighbouring locations (e.g. the Liza field in 2016 (Fugro, 2016) and the Payara development in 2018 (Fugro, 2019a). Sediments sampled in the Liza field were analysed by the National Laboratory Service, with metals concentrations reported within the Payara development analysed by Kaizen LAB.

Aluminium concentrations were above the MRV (< 50 µg/L) in three surface samples and one bottom sample, with the highest concentration (85 µg/L) reported from the surface of station EBSHHW02. Aluminium concentrations within the current survey were broadly comparable to those reported within the Payara development in 2018, when concentrations ranged from < 80.0 µg/L to 142 µg/L (Fugro, 2019a).

Arsenic concentrations ranged from 1.26 µg/L in the surface sample of station EBSHHW06 to 2.21 µg/L in the middle depth sample of station EBSHH_07, with a mean of 1.67 µg/L and low interstation variability (RSD 15 %). Arsenic concentrations within the current survey were broadly comparable to those recorded in historic datasets, in the Payara development (mean 1.70 µg/L; Fugro, 2019a) and the Liza field in 2016 (mean 1.43 µg/L; Fugro, 2016). Arsenic concentrations were below the US EPA CCC threshold of 36 µg/L in all samples (US EPA, 2018).

Mercury concentrations were below the MRV (< 0.100 µg/L) in all water samples, except the surface sample of station EBSHHW01 where a concentration of 0.119 µg/L was reported. Mercury concentrations within the current survey are broadly comparable to those reported in historic datasets, in the Payara development (majority < 0.01 µg/L, maximum 0.113 µg/L; Fugro, 2019a) and the Liza field in 2016 (all < 0.01 µg/L; Fugro, 2016). Mercury concentrations were below the US EPA CCC threshold of 0.94 µg/L in all samples (US EPA, 2018).

No other analysed metals exceeded their respective MRVs in any water samples acquired within the Hammerhead development. All other analysed metal concentrations were below their respective US EPA CCC thresholds (US EPA, 2018).

8. SEABED HABITATS

8.1 Introduction

To assess the habitats present within the survey area, detailed analysis of video and stills photography data was undertaken by experienced Fugro marine biologists/taxonomists. Video photography data were reviewed in conjunction with the still photographs, noting the locations of any observed change in sediment type and/or associated faunal community.

Appendix C provides the detailed video and photographic log. Appendix G provides detailed digital seabed stills photographs.

The 'Biotopes/Ecosystems Nomenclature, Habitats of South America' (Institute of Terrestrial Ecology, 1996) has been used to broadly classify the observed seabed habitats. Due to a lack of more detailed habitat guidelines and background literature for South American marine habitats, the European Nature Information System (EUNIS) habitat classification (EUNIS, 2012a) has also been used, which has comparable overarching descriptors of habitats. However, due to regionally different species, in- depth biotope complex classifications cannot be applied.

8.2 Results

8.2.1 Seabed Habitats and Fauna

The seabed observed at all drop-down stations comprised mud with minimal shell material and corresponded with areas of low sonar reflectivity. Analysis of the photographic data from these stations showed the seabed to be comprised of one broad habitat: 'Sublittoral soft seabeds (11.22) (Institute of Terrestrial Ecology, 1996), the equivalent EUNIS habitat was 'Sublittoral mud' (A5.3), "sublittoral mud and cohesive sandy mud extending from the extreme lower shore to offshore, circalittoral habitats". This biotope is predominantly found in sheltered harbours, sealochs, bays, marine inlets and estuaries and stable deeper/offshore areas where the reduced influence of wave action and/or tidal streams allow fine sediments to settle (EUNIS, 2012b).

Areas of high and moderate sonar reflectivity corresponded with exposed, elevated bedrock interspersed with sandy mud and varying proportions of gravel and shell material, running parallel to the shelf break on transects TR01 to TR06. These areas were assigned the broad habitat 'Deep-sea floor' (11.21) (Institute of Terrestrial Ecology, 1996), the EUNIS (2012) classification system allows this habitat to be spilt into two further categories: Areas of elevated, exposed bedrock were assigned 'Deep-sea rock and artificial hard substrata' (A6.1), deep-sea benthic habitats with substrates predominantly of bedrock, immobile boulders or artificial hard substrates (EUNIS, 2012c). The gravelly, muddy sand also observed at these transects were assigned the EUNIS (2012) classification of 'Deep-sea muddy sand' (A6.4), Deep-sea benthic habitats with substrates predominantly of muddy sand (EUNIS, 2012d).

Table 8.1 summarises the hierarchy of the assigned EUNIS (2012) classifications, and equivalent Biotopes/Ecosystems Nomenclature, Habitats of South America' Classification (1996), based on the video and photographic data.

Figure 8.1 displays example photographs of the assigned EUNIS (2012) classifications, and equivalent Biotopes/Ecosystems Nomenclature, Habitats of South America' Classification (1996), based on the video and photographic data.

Table 8.1: Habitat Classifications, Hammerhead Development

EUNIS (2012) Habitat Classification			**Biotopes/Ecosystems Nomenclature, Habitats of South America' Classification (1996)**
Environment Level 1	**Broad Habitat Level 2**	**Habitat Level 3**	
A Marine	A5 Sublittoral sediment	A5.3 Sublittoral mud	Sublittoral soft seabeds (11.22)
	A6 Deep-seabed	A6.1 Deep-sea rock and artificial hard substrata	Deep-sea floor (11.21)
		A6.4 Deep-sea muddy sand	
Notes: EUNIS = European Nature Information System			

8.2.1.1 Sublittoral Soft Seabeds (11.22) (Institute of Terrestrial Ecology, 1996)/Sublittoral Mud (A5.3) (EUNIS 2012)

This habitat, observed at all drop-down video stations, can be described as "benthic communities colonising soft sediments such as mud, sand or gravel of the infralittoral and circalittoral zones." (Institute of Terrestrial Ecology, 1996), the equivalent EUNIS (2012) classification is 'Sublittoral Mud' (A5.3). Epifauna was sparse within this habitat at the Hammerhead survey area. Sessile tax such as burrowing anemones (Cerianthidae), sea cucumber (Holothuroidea), carnivorous sponge (*Chondrocladia* sp.), sea pens (Pennatulacea) and possible buried xenophyophore (Xenophyophoroidea) were occasionally recorded. Mobile taxa were rarely observed and included shrimp (Caridea) and unidentified fish (Pisces). Faunal tubes, tracks and burrows were observed in the soft sediment.

8.2.1.2 Deep-sea floor (11.21) (Institute of Terrestrial Ecology, 1996)/Deep-sea Rock and Artificial Hard Substrata (A6.1) and Deep-sea Muddy Sand (A6.4) (EUNIS 2012)

This habitat, observed at all transects can be described as described as: "Bathyal, abyssal, hadal and hydro-thermal benthic communities of the continental slope, the abyssal plain and its features." (Institute of Terrestrial Ecology, 1996); and may be further categorised using the EUNIS (2012) classification system.

Fauna was sparse in areas classified further as deep-sea muddy sand (A6.4). Mobile taxa such as pencil urchin (Cidaridae), small unidentified fish (Pisces) and starfish (Asteroidea) were occasionally observed. Other taxa were also sparse with sea cucumbers (Holothuroidea) recorded. Faunal burrows arranged in a honeycomb formation were frequently observed.

Epifauna, specifically sessile taxa, was more diverse in areas further classified as 'deep-sea rock and artificial hard substrata' (A6.1). Sessile taxa observed in association with exposed bedrock include sponges, including encrusting, thin tubular, ramifying and cup growth forms (Porifera), coralline algae (Corallinales), sea fan (Gorgoniidae), sea whip (Octocorallia), faunal turf (Bryozoa/Hydrozoa/Porifera), black coral (Antipatharia including *Stichopathes* sp. and *Tanacetipathes* sp.) and stony coral (Scleractinia). Mobile taxa recorded were dominated by echinoderms including brittlestars (Ophiuroidea)

associated with sea fans and black coral, starfish (Asteroidea) and sea urchins (Diadematidae). Other mobile fauna observed included: lobster (Palinuridae), damsel fish (Pomacentridae), jack fish (*Seriola* sp.), and small, unidentified reef dwelling fish (Pisces).

9. SEDIMENT MACROFAUNA

9.1 Introduction

This section presents the results of the macrofaunal analysis of samples collected across the survey area. A total of eight stations were sampled for macrofaunal content using a US NEL 0.25 m^2 box corer. Each of the 0.25 m^2 USNEL box core samples were subsampled to provide two macrofaunal samples (0.1 m^2 each), both of which were processed for analysis (FA and FB). Appendix B provides full details of the analytical techniques employed.

The sediment macrofauna is defined as those animals living in or on the seabed that are retained on a sieve mesh of 0.5 mm. Before any analysis was undertaken, the reported macrofaunal dataset underwent rationalisation to prevent spurious enhancement of community statistics and allow comparison to historical datasets. Analysis was completed with juveniles removed from the dataset as juveniles are not considered part of the permanent community. Any phyla considered parasitic were also removed for this reason. Several damaged and indeterminable specimens were reported within the original dataset. Where damaged specimens were indeterminable from identified taxa and could be merged without reducing taxonomic resolution, specimens were merged (e.g. *Spiophanes* and damaged Spionidae were merged to Spionidae). However, several damaged specimens were removed from the rationalised dataset prior to analysis to avoid spurious enhancement of diversity indices.

Following rationalisation, intrastation variability for the survey area varied from moderate to high. Stations ranged in average similarity between samples from 18.5 % (station EBSHH_05) to 41.4 % (station EBSHH_08). The data from samples for each station were combined to obtain numbers of taxa and individuals per 0.2 m^2 for each station, as well as diversity indices. Individual sample data were combined in this manner to achieve a more accurate representation of the numbers of taxa and individuals present in a given area of the seabed. This is accepted practise in marine benthic monitoring.

The results of the macrofaunal analysis are presented in the form of figures and tables; the main features of the communities identified are highlighted in the text. A full list of taxa identified and enumerated (individuals per 0.1 m^2) from the survey area are presented in Appendix H.

9.2 Results

9.2.1 Phyletic Composition

Table 9.1 summarises the abundance of taxonomic groups identified across the survey area and Figures 9.1 and 9.2 display the data graphically.

A total of 190 taxa and 608 individuals were identified within grab samples from the survey area. Of these taxa, 45 were recorded as juveniles, parasitic or damaged specimens. Additionally, 10 indeterminable taxa were merged into five taxa. To represent the permanent macrofaunal community and to avoid spurious enhancement of the species list, the dataset was rationalised and these taxa were removed prior to statistical analysis (see Appendix H).

The rationalised data comprised 140 benthic taxa, of which 57 (40.7 %) were arthropods, 46 (32.9 %) were annelids, 26 (18.6 %) were molluscs, 5 (3.6 %) were echinoderms and 6 (4.3 %) were other phyla, specifically sea anemones (within the phylum Cnidaria), ribbon worms (Nemertea) and peanut worms

(Sipuncula). A total of 477 individual animals were identified in the rationalised data, of which 162 (34.0 %) were arthropods, 132 (27.7 %) were annelids, 124 (26.0 %) were molluscs, 22 (4.6 %) were echinoderms and 37 (7.8 %) were other phyla (Table 9.1).

Table 9.1: Taxonomic Groups, Hammerhead Development

Taxonomic Group	Number of Taxa	Composition of Taxa [%]	Abundance	Composition of Individuals [%]
Annelida	46	32.9	132	27.7
Arthropoda	57	40.7	162	34.0
Mollusca	26	18.6	124	26.0
Echinodermata	5	3.6	22	4.6
Other phyla	6	4.3	37	7.8
Total	**140**	**100**	**477**	**100**

Notes:
Other phyla include: Cnidaria, Nemertea and Sipuncula
Macrofaunal samples were processed through a 0.5 mm sieve

Figures 9.1 and 9.2 illustrate the phyletic composition of taxa and individuals for each station (per 0.2 m^2), respectively. Consideration by station facilitates spatial comparison and highlights the broad similarities between stations across the survey area. When taxa were considered, arthropods, annelids and molluscs comprised the three most diverse phyla at all stations, although not necessarily in this order. Arthropods, annelids and molluscs accounted for a combined total of ≥ 84.2 % of the taxa at each station (Figure 9.1). When individuals were considered, these phyla also comprised the three most abundant phyla at the majority of stations, accounting for ≥ 79.2 % of the individuals at each station (Figure 9.2).

Despite these broad similarities, some differences were apparent. The single most diverse and most abundant phylum demonstrated differences between stations, and included arthropods, annelids and molluscs (Figures 9.1 and 9.2). Additionally, at station EBSHH_07, no echinoderms were reported (Figures 9.1 and 9.2), other phyla were more abundant than arthropods and the highest proportion of mollusc taxa and individuals was observed (Figure 9.2).

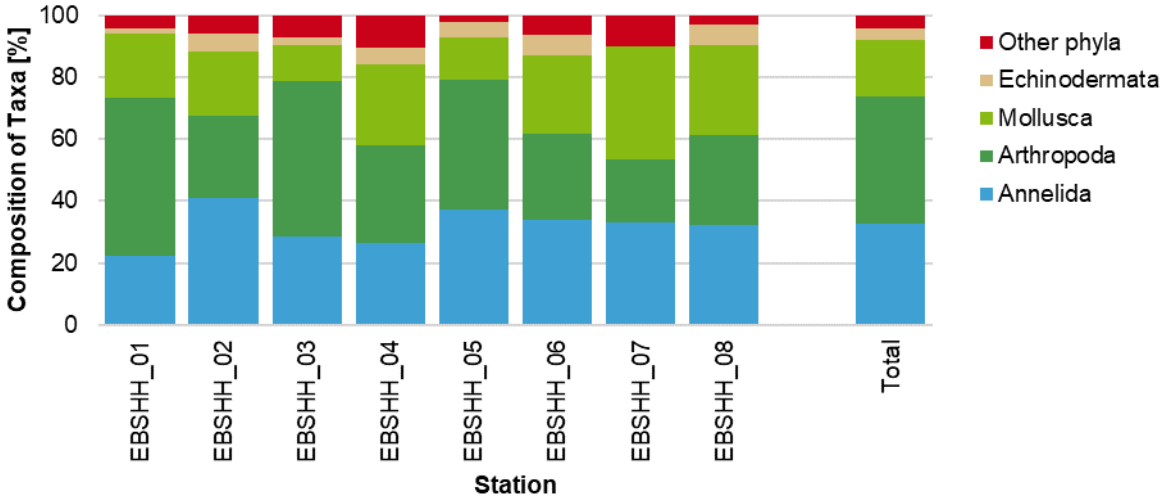

Figure 9.1: Phyletic composition of taxa, Hammerhead development

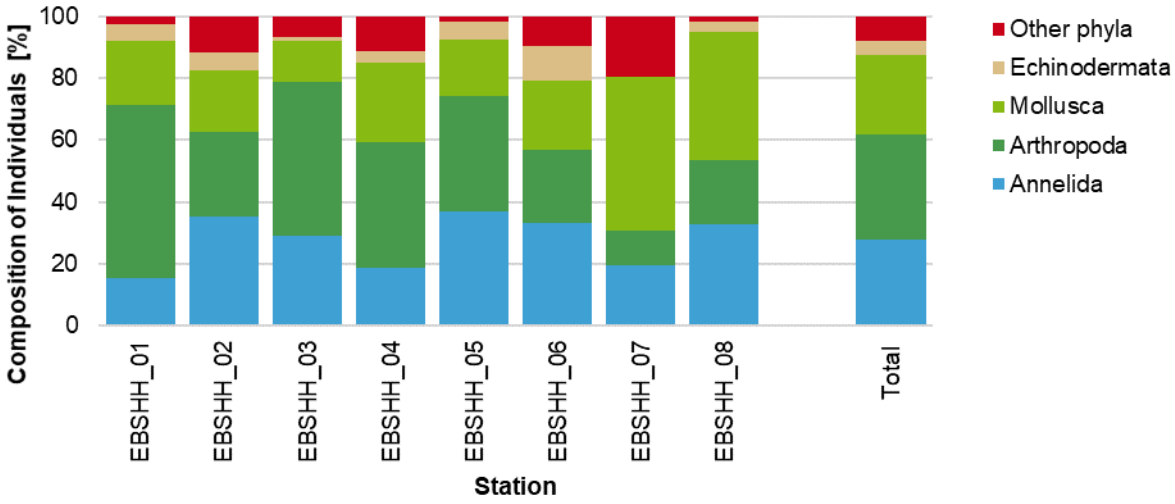

Figure 9.2: Phyletic composition of individuals, Hammerhead development

9.2.2 Characteristic Taxa

Table 9.2 presents the dominant taxa within the survey area and Table 9.3 presents the most abundant taxa per station. Due to the number of taxa reported at low abundance, often as a single specimen, the top five taxa were not distinguishable at the majority of stations. Where this occurred, only the taxa present within the top five taxa at other stations within the survey area have been listed (Table 9.3). Consequently, these taxa will be referred to as characteristic taxa throughout this section.

By ranking the taxa recorded at each station in terms of density and summing the rank scores for all stations to assign an overall rank abundance and dominance for each taxon, it is possible to examine which species were consistently abundant as well as dominant throughout the survey area. The dominance rank is less susceptible to bias caused by species that occur in high densities in only a few of the samples analysed.

All taxa were reported at low mean abundance within the survey area. The most abundant taxon, the bivalve mollusc *Ennucula*, was reported with a mean abundance of 3 individuals per 0.2 m^2 and was not present within the top ten most dominant taxa. The high rank abundance of *Ennucula* in comparison to rank dominance is due to the presence of this mollusc at only six of the eight stations (62.5 %; Table 9.2) and also it's relatively high abundance at the shallowest stations EBSHH_07 and EBSHH_08 (Appendix H).

There was some fidelity between rank abundance and rank dominance across the survey area, with eight of the top ten most abundant taxa also reported within the top ten most dominant taxa. The most dominant taxon was the tanaid crustacean *Typhlotanais*, which was present at abundances of ≥ 2 individuals per 0.2 m^2 at five of the eight stations. Isopod crustaceans of the family Desmosomatidae and molluscs of the class Caudofoveata were joint second most dominant taxa, with Desmosomatidae also the second most abundant taxon (Table 9.2).

None of the top ten most abundant or dominant taxa were reported within all stations across the survey area, with isopod crustaceans of the family Desmosomatidae, the polychaetes *Ophelina* and those of the family Spionidae all reported from seven of the eight stations (87.5 %; Table 9.2). This heterogeneity within the macrofaunal community was highlighted when the characteristic taxa at each station were considered. The most abundant taxon differed at each station, in part due to the low abundances recorded across the survey area. The most abundant taxa were from numerous phyla. and included the molluscs *Microgloma mirmidina* and *Ennucula*, the arthropods *Apseudes* sp. B and Desmosomatidae, the annelid *Aricidea*, the brittlestar *Ophiotholia* and the peanut worms *Aspidosiphon* (*Akrikos*) *zinni* and *Phascolosoma*? (Table 9.3). Of these, Desmosomatidae were present within the characteristic taxa at four of the eight stations, with *Aspidosiphon* (*Akrikos*) *zinni* and *Ophiotholia* within the characteristic taxa at three stations.

Table 9.2: Dominant Taxa by Rank Abundance and Dominance, Hammerhead Development

Taxon	Rank Abundance	Mean Station Abundance [0.2 m^2]	Rank Dominance	Frequency [%]
*Ennucula**	1	3	14*	62.5
Desmosomatidae	2	2	2	87.5
Typhlotanais	3	2	1	75.0
Ophiotholia	3	2	6	75.0
Aspidosiphon (*Akrikos*) *zinni*	5	2	7	62.5
Phascolosoma?*	6	2	13*	25.0
Ophelina	6	2	5	87.5
CAUDOFOVEATA	6	2	2	75.0
Fauveliopsis	9	1	4	75.0
Microgloma mirmidina	9	1	8	75.0
Spionidae†	11†	1	10	87.5
Dacrydium†	13†	1	9	37.5

Notes:
Rank abundance is calculated based on the total number of individuals across the survey area
Rank dominance is calculated based on frequency and abundance
Frequency = Percentage of the stations from which the taxa were recorded
Top ten most abundant or dominant taxa only are included
* = Present within the top ten most abundant taxa across the survey area, but not the top ten most dominant
† = Present within the top ten most dominant taxa across the survey area, but not the top ten most abundant

Table 9.3: Top 5 Most Abundant Taxa at Each Station, Hammerhead Development

Station EBSHH_01	Ind [0.2 m²]	Cum [%]	Station EBSHH_02	Ind [0.2 m²]	Cum [%]

Nine other taxa*, including *Fauveliopsis*, *Ophelina*, CAUDOFOVEATA and *Yoldiella*	2	38.9	*Aspidosiphon* (*Akrikos*) *zinni*	5	15.3
			Typhlotanais	5	22.2
			Anobothrus	3	26.4
			Limopsis	3	30.6
Station EBSHH_07	**Ind [0.2 m²]**	**Cum [%]**	**Station EBSHH_08**	**Ind [0.2 m²]**	**Cum [%]**
Phascolosoma?	9	14.5	*Ennucula*	13	22.4
Neilonella?	8	27.4	*Paralacydonia paradoxa*	5	31.0
Ennucula	6	37.1	*Ophelina*	3	36.2
Semelidae sp. A	4	43.5	VENEROIDEA sp. A	3	41.4
Two other taxa*	3	53.2	Seven other taxa*, including *Fauveliopsis*, Harpiniinae and TANAIDOMORPHA sp. A	2	65.5

Notes:
Ind = Number of individuals of the taxa within the station (0.2 m²)
Cum = Cumulative percentage of the individuals relative to the total number of individuals recorded within the station (0.2 m²)
* = Due to the number of taxa reported at low abundance, the top five taxa were not distinguishable at the majority of stations. Where this occurred, only the taxa present within the top five taxa at other stations have been listed

9.2.3 Species Accumulation and Richness Estimation

Figure 9.3 displays the species accumulation plot. This was generated using sample data (0.1 m²) in PRIMER v7. The observed number of taxa obtained through repeated sampling (Sobs) were cumulatively plotted, as were richness estimates from repeated sampling as calculated by the Chao1, Chao2, Jacknife1 and Jacknife2 formulae. All displayed curves were smoothed (by random permutation of the data points) to aid interpretation.

The observed species accumulation curve was a relatively constant slope that appeared unlikely to be close to reaching the asymptote, suggesting that a proportion of the macrofaunal community within the survey area had not been detected by the sampling undertaken. The Jacknife richness estimators

followed a similar pattern, although Chao1 and Chao2 appeared to be approaching an asymptote. For Chao2 an increase in species count for a low number of samples was evident, which was reflective of the high number of taxa reported as individual specimens across the survey area (roughly a third of the taxa recorded; Appendix H), with the initial spike smoothed out as more samples were included in the calculation.

The richness estimators suggest that a moderate to high proportion of the survey area has described by the sampling effort undertaken, with estimates for the total macrofaunal diversity of the area ranging from 189 taxa (Chao1) to 214 taxa (Jacknife2), in comparison to the 140 taxa recorded. These estimates suggest that between 65.4 % and 74.1 % of the area's total faunal diversity has been detected by the sampling undertaken.

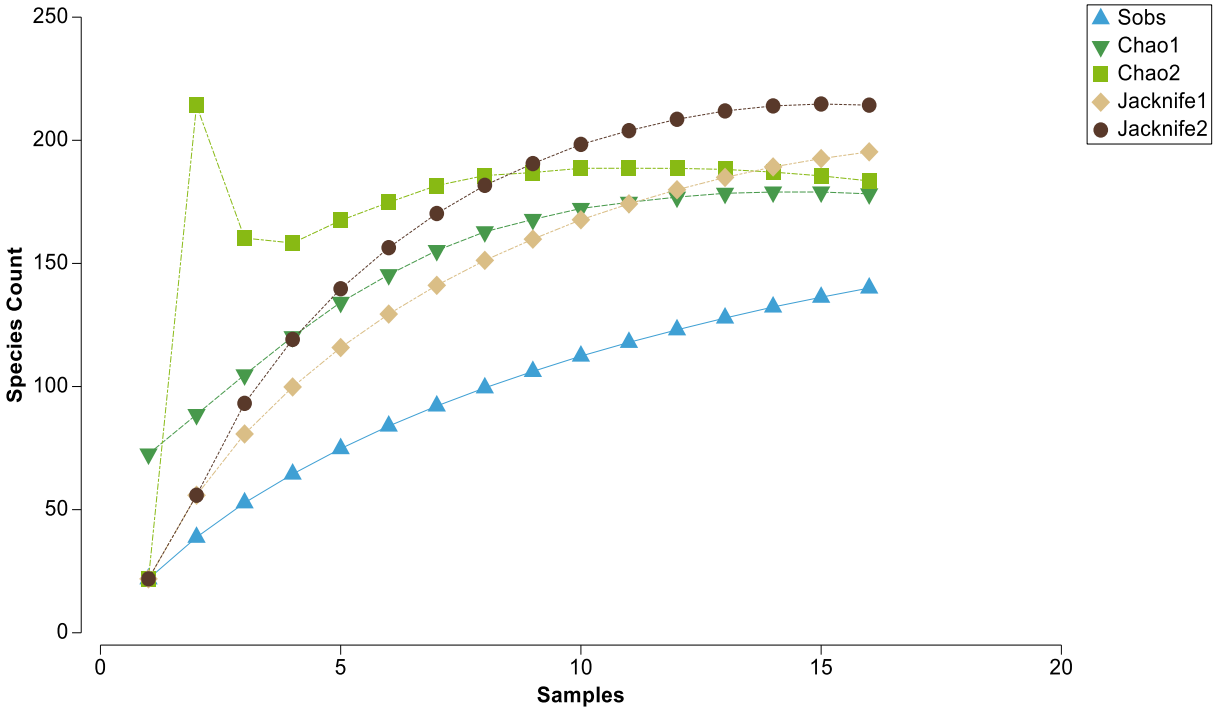

Figure 9.3: Species accumulation plot for sample data (0.1 m^2), Hammerhead development

9.2.4 Community Statistics

Table 9.4 presents the number of taxa and individuals identified from each station along with several commonly used diversity and evenness statistics. Figure 9.4 spatially displays the number of individuals per 0.2 m^2 overlaid on bathymetry data.

The number of taxa per 0.2 m^2 ranged from 19 at station EBSHH_04 to 49 at station EBSHH_01, with a mean of 37 and low interstation variability (RSD 28 %). The mean number of taxa per 0.2 m^2 was higher than that reported in slightly deeper waters (ca. 1800 m to ca. 2100 m) within the neighbouring Payara development in 2018 (mean 12; Fugro, 2019a).

The number of individuals per 0.2 m^2 ranged from 27 at station EBSHH_04 to 77 at station EBSHH_01, with a mean of 60 and low interstation variability (RSD 28 %) and no clear spatial pattern (Figure 9.4). The mean number of individuals per 0.2 m^2 was broadly comparable to that estimated from a wide depth

range (ca. 500 m to ca. 2800 m) in the Liza field in 2016 (mean 40, Fugro, 2016) and higher than that reported within the Payara development in 2018 (mean 19; Fugro, 2019a).

Diversity was high across the survey area, based on the Shannon-Wiener index ($H'Log_2$) referenced to the five ecological statuses outlined in Dauvin et al. (2012), classified as: bad if 0.00 to 1.00, poor if 1.00 to 2.00, moderate if 2.00 to 3.00, good if 3.00 to 4.00 and high if ≥ 4.00. Shannon-Wiener diversity index ranged from 4.11 at station EBSHH_04 to 5.38 at station EBSHH_01, with a mean of 4.88 and low interstation variability (RSD 10 %). The Brillouin's index (Hb) largely mirrored the Shannon-Wiener index across the survey area. The mean Shannon-Wiener diversity index reported in the current survey was higher than reported in slightly deeper waters within the Payara development in 2018 (mean 3.19; Fugro, 2019a) and from a wide depth range in the Liza field in 2016 (mean 2.42, Fugro, 2016).

The Pielou's evenness index (J) is a measure of the distribution of individuals between taxa. The Simpsons index of dominance considers the number and relative abundance of taxa, measuring community diversity by assigning higher weight to dominant taxa. Consequently, the complement of the Simpsons index of dominance (expressed as 1 – λ) also gives an indication of evenness. Evenness was high across the survey area indicating that faunal abundances were evenly distributed across the taxa recorded. The Pielou's evenness index ranged from 0.893 at station EBSHH_08 to 0.983 at station EBSHH_05 with a mean of 0.948 and low interstation variability (RSD 4 %). The complement of the Simpsons index of dominance (1 - λ) largely mirrored the complement of the Pielou's evenness index across the survey area. The mean Pielou's evenness index reported in the current survey was broadly comparable to that reported from a wide depth range in the Liza field in 2016 (mean 0.95, Fugro, 2016) and in slightly deeper waters within the Payara development in 2018 (mean 0.926; Fugro, 2019a).

Table 9.4: Macrofaunal Community Statistics (0.2 m^2), Hammerhead Development

Station	Numbers		Diversity Indices		Evenness	
	Taxa	Individuals	Shannon-Wiener ($H'Log_2$)	Brillouin (Hb)	Pielou (J)	Simpson (1 - λ)
EBSHH_01	49	77	5.38	3.04	0.958	0.971

Notes:
SD = Standard deviation
RSD = Relative standard deviation
* = Mean and RSD values estimated from an environmental survey in the neighbouring Payara development in 2018, in depths of ca. 1800 m to ca. 2100 m. 0.2 m^2 stations processed through a 0.5 mm sieve (Fugro, 2019a)
† = Mean and RSD values estimated from an environmental survey in the neighbouring Liza field in 2016, in depths of ca. 500 m to ca. 2800 m. 0.1 m^2 stations processed through a 0.5 mm sieve. Number of taxa, diversity and evenness indices presented as original data. Number of individuals per 0.2 m^2 estimated from 20 per 0.1 m^2 and presented for comparison (Fugro, 2016)

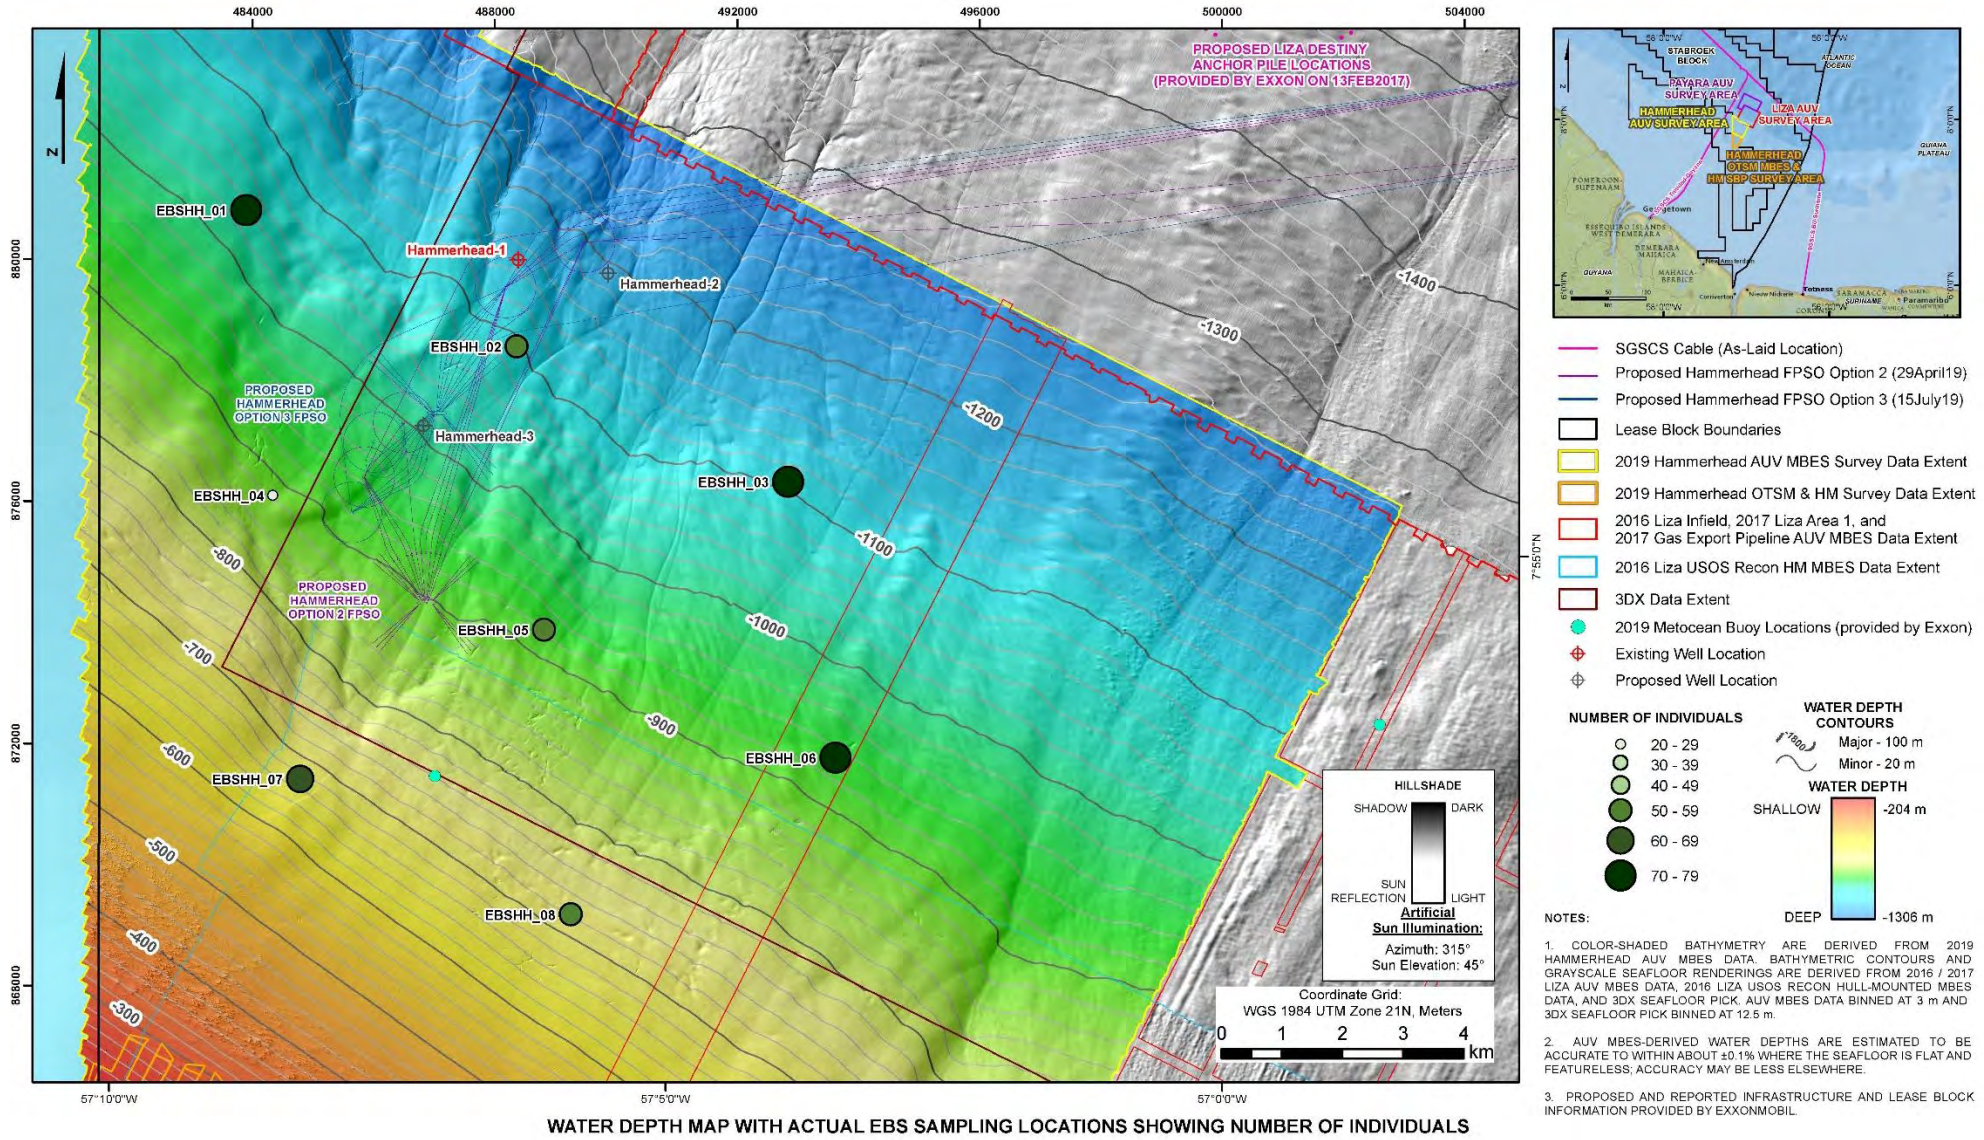

Figure 9.4: Number of individuals (0.2 m^2) overlaid on bathymetry data, Hammerhead development

9.2.5 Investigation of Faunal Similarities

Univariate statistics can summarise large and complex datasets (see Appendix B.3) to a certain extent, condensing a large data matrix to a much more manageable form and allowing direct comparison of variables. Multivariate analysis examines relationships among multiple variables at the same time, which allows assessment of structure and provides synthesised conclusions with less error and more robustness. In doing so, subtle trends in the data may be elucidated.

Various multivariable techniques were applied to the survey area data to investigate such patterns of similarity within the macrobenthic community, which were then further considered with the results from the univariate analyses.

Figures 9.5 and 9.6 present the multivariate statistical analyses of the community: hierarchical agglomerative clustering (CLUSTER) and non-metric multi-dimensional scaling (nMDS) from PRIMER.

9.2.5.1 Cluster Analysis

CLUSTER analysis groups stations according to their faunal similarity and the results are presented in the form of a dendrogram. Figure 9.5 presents the CLUSTER analysis dendrogram and demonstrates the pattern of similarity of untransformed station data. The SIMPROF algorithm was used to identify statistically significant (P = 0.05) differences between stations, with significant splits depicted as black lines and non-significant splits as red lines. Statistically significant splits may not be ecologically significant (Clarke et al., 2008), with ecological significance considered in subsequent sections of this report.

There was a low to moderate degree of faunal similarity across the Hammerhead development survey area, with stations clustering with between 19.3 % and 37.4 % similarity. From the dendrogram, two statistically significant clusters were apparent:

- Cluster A, consisting of two stations to the south of the survey area (stations EBSHH_07 and EBSHH_08 in water depths of < 800 m), grouped together with 33.3 % similarity to each other;
- Cluster B, consisting of the remaining six stations in deeper water (stations EBSHH_01 to EBSHH_06 in water depths of > 800 m), grouped with 22.5 % similarity to each other and 19.3 % similarity to cluster A.

The results of the CLUSTER analysis partially reflected those of the univariate analysis. When considered in conjunction with the characteristic taxa, it was apparent that the bivalve mollusc *Ennucula* was present in relatively elevated abundance (≥ 5 individuals per 0.2 m^2) at stations in cluster A only (Table 9.3). When community statistics were considered, it was apparent that the lowest evenness (both J and 1 - λ) was reported from stations in cluster A (Table 9.4).

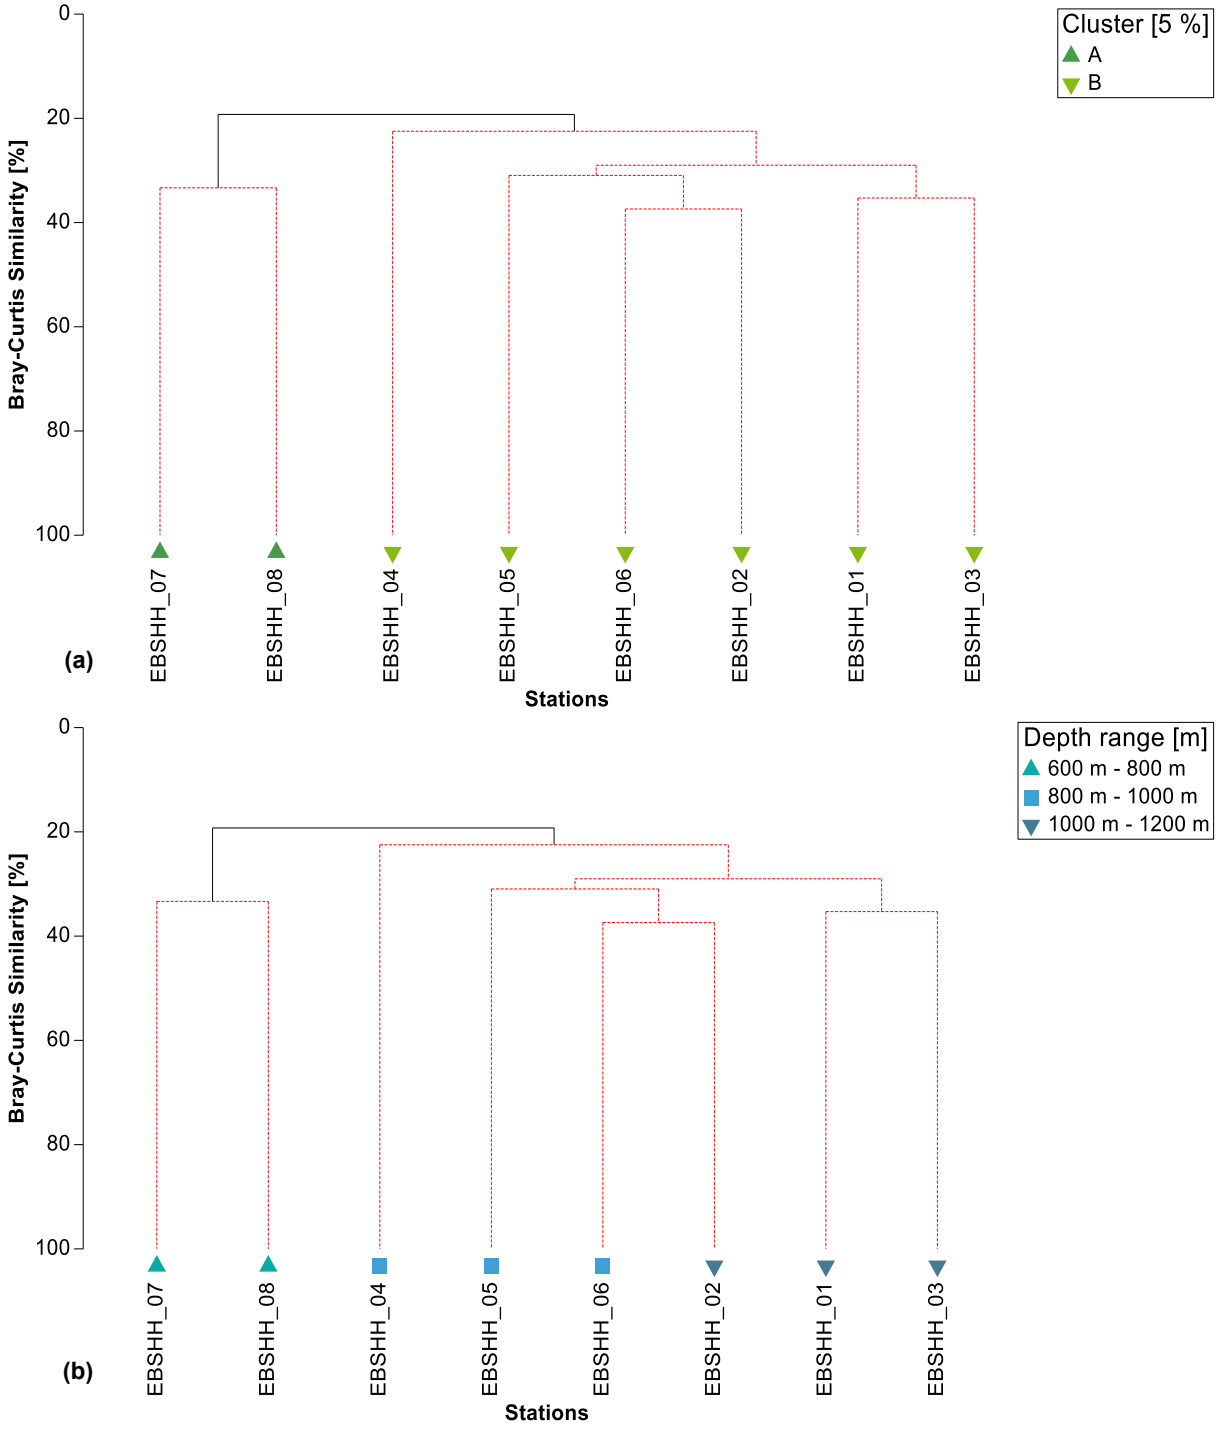

Figure 9.5: Classification by Bray-Curtis similarity for untransformed macrofaunal abundance station (0.2 m^2) data, Hammerhead development (a) clusters at 5 % significance (b) depth overlaid on clusters

9.2.5.2 Non-metric Multidimensional Scaling (nMDS)

Figure 9.6 displays the results of the nMDS, which is an ordination technique that arranges stations on a two-dimensional plot, so that their relative distances from each other reflect their faunal similarities. Depth has been considered as a factor within the nMDS. The stress coefficient of 0.05 provides a good representation of the data (Clarke and Warwick, 2001). This plot supports the results of the CLUSTER analysis and highlights the influence of depth, or parameters associated with depth (e.g. sediment

characteristics) on the macrofaunal community across the survey area. The macrofaunal communities at stations in shallower water (specifically stations EBSHH_07 and EBSHH_08) were more similar to one another than to other stations. Additionally, the macrofaunal community at two stations in deeper water to the north of the survey area (specifically stations EBSHH_01 and EBSHH_03) were more similar to one another than to other stations.

The nMDS highlights that the macrofaunal community at station EBSHH_04 was less than 30 % similar to all other stations. This reflects the univariate statistics, with station EBSHH_04 featuring the lowest number of taxa, individuals and consequently diversity (both H'Log$_2$ and Hb) across the survey area (Table 9.4). The separation of stations EBSHH_01 and EBSHH_03 within the nMDS analysis can also be partially explained by the univariate analysis, as stations EBSHH_01 and EBSHH_03 featured the highest number of taxa and the highest Brillouins diversity index within the survey area (Table 9.4).

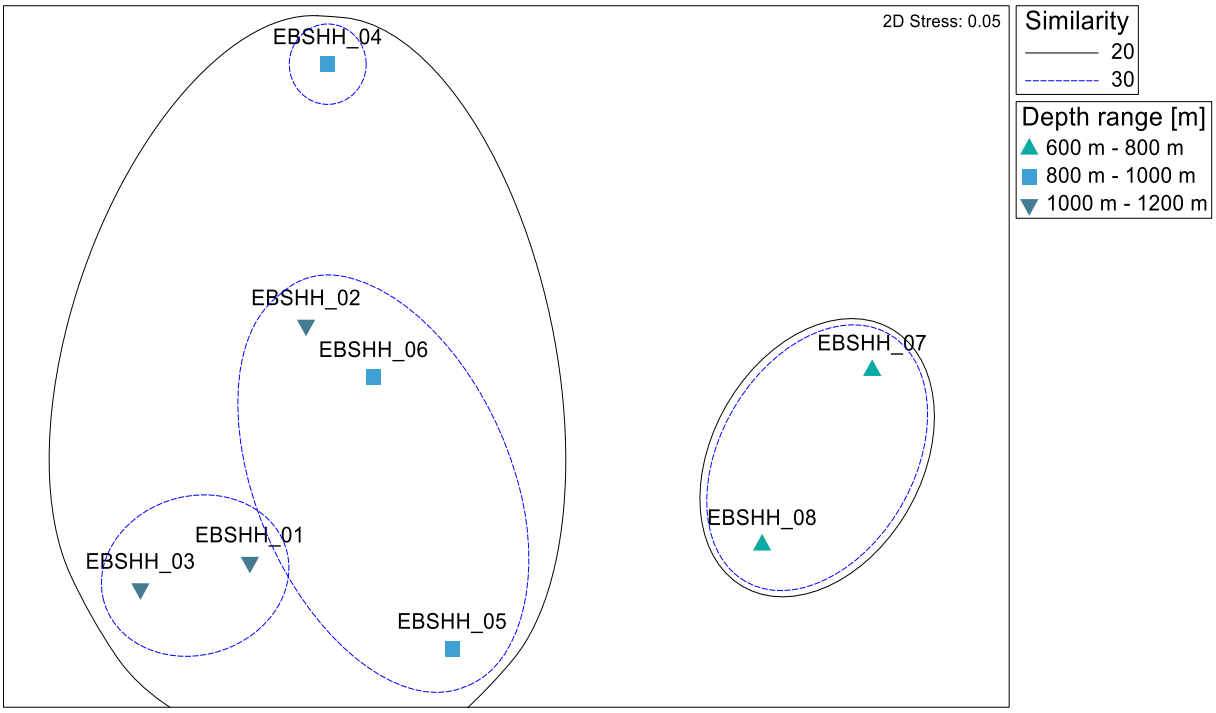

Figure 9.6: Non-metric multidimensional scaling (nMDS) orientation by Bray-Curtis for untransformed macrofaunal abundance station (0.2 m^2) data with consideration of depth, Hammerhead development

9.2.5.3 Similarity Percentage Analysis (SIMPER)

SIMPER analysis highlighted that the differences in the macrofaunal community across the survey area were largely reflective of elevated abundance (albeit still relatively low abundances) of several taxa within stations sampled within shallower water (< 800 m) and the presence or absence of taxa associated with different depth ranges.

The polychaete *Paralacydonia paradoxa*, the bivalve molluscs *Ennucula* and *Ledella pustulosa* and those of the family Veneroidea sp. A were all present at both stations sampled in water depths of 600 m to 800 m (cluster A) but were largely absent (or present at low abundance) from stations sampled in water depths of 800 m to 1200 m (cluster B). Conversely, the tanaid arthropod *Apseudes* sp. A was

present at the majority of stations sampled in water depths of 800 m to 1200 m (cluster B) and the polychaete *Aricidea* and bivalve mollusc *Dacrydium* were present in relatively high abundance at several of these, whilst all three taxa were absent from both stations sampled in water depths of < 800 m (cluster A).

The polychaete *Siboglinum* was present at all stations sampled in water depths of > 1000 m but not reported elsewhere in the survey area. The tanaid arthropod *Apseudes* sp. B was present at stations EBSHH_01 and EBSHH_03 only, both sampled in water depths of > 1000 m. Conversely the previously mentioned bivalve mollusc *Ennucula* was present at all stations sampled in water depths of < 1000 m but absent from all stations sampled in water depths of > 1000 m.

In summary, SIMPER analysis highlighted that the taxa largely responsible for the observed differences in the macrofaunal community across the survey area were restricted by depth, or parameters associated with depth. It is likely that these differences in the macrofaunal community are partially due to the low abundance of all taxa reported.

The relationship between macrofauna communities and physical and chemical determinants will be discussed further in Section 10.

10. DISCUSSION

10.1 Introduction

The survey and analytical strategies were designed to provide a comprehensive baseline dataset of the biological and physico-chemical characteristics in the vicinity of the Hammerhead development. An assessment of likely habitats and biotopes, with particular attention to environmentally sensitive habitats and species, was also conducted. The sampling plan included the collection of surface sediment from eight stations located in proximity to the proposed drill centres and wells for physico-chemical and biota analysis. The surface (0 cm to 2 cm) sediment samples collected (Section 3) were analysed for total TOC, hydrocarbons (including 2 to 6 ring aromatics) and heavy metal content. Selected physical characteristics were analysed using surface sediment samples of 0 cm to 5 cm. Macrofaunal analysis (> 0.5 mm) was carried out on duplicate 0.1 m^2 grab samples at each station. Water column samples were collected at three depths and analysed for TSS, TOC, hydrocarbons and metals content.

The previous sections of this report have presented the data generated from the analysis programme stated above with the aid of data tables and graphics. This discussion section will review the data with respect to regional comparison data from previous surveys in the area including the neighbouring Payara development (Fugro, 2019a) and the Liza development (Fugro, 2016). The data from this report were also compared to appropriate reference values (Buchman, 2008; US EPA, 2018) to determine whether the concentrations present in the sediments and water columns may potentially have a detrimental effect on the benthic communities in the Hammerhead development survey area.

In addition to the comparison of the analytical data against available references, statistical correlations of the sediment parameters recorded with the chemical and biological determinants in the survey are summarised (for the main environmental parameters) in Appendix I. The statistical analysis chosen was the Spearman's rank correlation coefficient (Spearman, 1904), sometimes referred to as Spearman's rho. This coefficient is used to test the association between two reported values for statistical dependence. It is a measure of rank correlation, or the similarity of the orderings of the data when ranked by each of the values. Correlations can only suggest a relationship and do not prove a causal link between status of the chemical or physical nature of the seabed and the infaunal community composition. Correlations occur as both positive and negative: they are positive when both reported values increase or decrease in unison, whilst negative correlations indicate that as one value increases the other decreases and vice-versa. Commonly observed positive correlations would include such variables as THC and PAH whereas common negative correlations would typically include factors such as distance from oil and gas infrastructure and THC (i.e. the farther from a platform, the lower the level of contamination observed).

Correlations analysis indicated that some correlations were apparent between intrinsic physico-chemical parameters within sediments, suggesting that trends in chemical determinants were influenced by both depth and sediment characteristics, with higher metals concentrations at deeper stations and those with a smaller particle size. However, the low variation demonstrated in the datasets summarised within the preceding sections of this report suggest that these may not be true ecological correlations. Whilst correlations are included within Appendix I, they have not been discussed in further detail.

10.2 Sediment Characterisation

The general physical and chemical characteristics of sediment particles have a significant effect on how other chemical components and biological species interact with seabed sediments. For example, the silt/clay fraction is known to adsorb petroleum hydrocarbons/heavy metals from seawater and through this pathway, these chemicals become incorporated into the sediment system (Meyers and Quinn, 1973). Granulometry data can therefore be critical when interpreting chemical and biological data obtained in this type of benthic study. In addition, since waste discharges (such as drill cuttings) often possess significantly different physical characteristics from the natural sediments present in the area, such data may also provide some information on the spread of discharged material.

With regard to macrofaunal communities, the species distributions and community structure can be greatly influenced by the nature of the sediment, which represents the effects of a complex set of hydrological factors, such as water movement, turbulence and suspended load, at one particular point in time. Some animals have a behavioural preference for sediment of a particular grain size (Meadows, 1964; Gray, 1981), while this factor and organic matter content are closely associated with other properties of the sediment such as density, porosity, permeability, oxygenation and bacterial count (Buchanan, 1984), all of which affect animal functions such as locomotion, attachment, tube construction and feeding. Specifically, the proportion of fine (silt/clay) material often influences the distribution of macrofaunal communities.

Sediments within the Hammerhead survey area demonstrated moderate interstation variability (RSD 40 %) in mean diameter, low variability for the proportion of fines (RSD 9 %), moderate variability for the proportion of sand (RSD 53 %) and high variability in gravel (RSD 107 %) content. Station EBSHH_07 displayed a higher mean particle size (18 µm) due to the higher proportions of sand (32.07 %) and gravel (0.09 %) recorded at this station.

Using the Folk (1954) sediment description in situ, the seabed was reported to comprise mud. This was supported in the laboratory by the Folk description (BGS modified) and the Wentworth (1922) classification. The Folk description (BGS modified) described the sediment as sandy mud at all stations except stations EBSHH_04 and EBSHH_05 where sediment was described as mud. The Wentworth (1922) classification described sediments across the majority of the survey area as fine silt, with very fine silt recorded at stations EBSHH_03 and EBSHH_04, and medium silt at station EBSHH_07. Sediments were described as very poorly sorted across the survey area. All stations were dominated by the fines fraction. The composition of sediments along the Guyana coast is influenced by riverine discharges from the Amazon basin, which are transported northwards via ocean currents (Eisma and Van der Marel, 1971). Secondary inputs are likely to be the discharge of sediments from the Essequibo-Demerara drainage basin (Nota, 1958). The quantity of gravel was highly variable across the Hammerhead survey area, with station EBSHH_07 having a slightly higher gravel content when compared to the other stations. All stations were classified as the biotope complex ‘Sublittoral soft seabeds’ (11.22; Table 8.1) (Institute of Terrestrial Ecology, 1996)’. This was further corroborated by the results of the PSD.

The sediment within the Hammerhead survey area comprised a lower proportion of gravel (mean 0.03 %) than available comparable datasets (e.g. the Payara development (mean 0.12 %; Fugro, 2019a), the Liza field in 2016 (mean 0.11 %; Fugro 2016). The proportion of fines within the

Hammerhead survey area (mean 85.00 %) was higher than the mean recorded in the Payara development (mean 44.5 %; Fugro, 2019a) and the Liza field (mean 60.78 %; Fugro, 2016).

The proportion of TOC within sediments in the Hammerhead survey area was low (mean 0.64 %) but is higher than had previously been reported in the Payara development (mean 0.31 %; Fugro, 2019a) and the Liza field (mean 0.32 %; Fugro, 2016).

10.3 Sediment Hydrocarbons

10.3.1 Total and Aliphatic Hydrocarbons

Marine sediments contain hydrocarbons derived from many sources which enter the marine environment via three general processes: biosynthesis (marine and land organisms biosynthesise hydrocarbons), geochemical processes (submarine and coastal/terrestrial oil-seeps) and anthropogenic sources (from accidental or intentional discharge of fossil fuel) (Farrington and Meyer, 1975; Myers and Gunnerson, 1976). Anthropogenic hydrocarbon inputs to the marine environment include marine transportation, offshore oil production, coastal oil refineries, accidental shipping losses, industrial and municipal waste (which includes sewage and dredged spoils). A significant contribution to the global budget enters the marine environment via urban and river run-off, atmospheric deposition (from combustion sources including PAHs) and natural seepages (Johnston, 1980; Dicks et al., 1987; NSTF, 1993; OSPAR, 2000; 2010).

Biosynthesised hydrocarbons are ubiquitous in the marine environment (Harada et al., 1995; Parinos et al., 2013). Odd carbon number, long chain n-alkanes are widely distributed in the plant kingdom (Eglinton et al., 1962; Douglas and Eglinton, 1966; Bush and McInerney, 2013) as components of cuticle waxes. These are common on the surfaces of leaves, stems, flowers and pollen and their presence in sediment is indicative of terrestrial inputs from adjacent land masses. Relatively high concentrations of nC_{29}, nC_{31} and nC_{33} are therefore a common feature of many marine sediments (Farrington et al., 1977).

The gas chromatographic profiles collated from the survey area shared a common underlying hydrocarbon distribution. The chromatograms all contained a trace level homologous series of resolved n-alkanes from nC_{12} to nC_{36}. The profiles also contained a trace level unresolved ‘hump’ covering the nC_{19} to nC_{36} range. This feature is the UCM and is composed of a wide range of compounds, including cycloalkanes, which remain after substantial weathering and biodegradation of petrogenic hydrocarbons (Farrington et al., 1977). The presence of the UCM in the samples suggests some contribution to the sediments from petroleum hydrocarbon sources, possibly attributed to fossil fuel discharges from historic or current industrial activities in the marine environment (such as shipping or oil and gas development) or via terrestrial run-off. Evidence of terrestrial run off was observed through the slight prevalence of the n-alkanes nC_{29}, nC_{31} and nC_{33}, indicating trace inputs of biogenic material such as plant waxes. The prominent peak prior to nC_{14} at stations EBSHH_01, EBSHH_02, EBSHH_04, EBSHH_05 and EBSHH_08 may be a characteristic of the survey area or may have been introduced through sampling methods. The profiles observed at the Hammerhead survey area indicate background sediments.

The total hydrocarbon content (THC) reported for the survey area displayed low variability (RSD 22 %). The current survey area had a mean THC value of 2.6 µg/g, higher than the mean THC observed at the

Payara development (0.7 µg/g; Fugro, 2019a). Figure 10.1 displays the Hammerhead development mean THC value alongside regional comparable data. No spatial trends in THC were apparent, with any variation between stations likely to be a result of natural small-scale heterogeneity in sediment characteristics and associated THC values.

The ratio of odd to even carbon numbered normal alkanes is termed the carbon preference index (CPI) and has been calculated over various chain length ranges. Elevated ratios (i.e. those > 1.00) over the nC_{12} to nC_{36} carbon range are due to the domination of the odd-chain length n-alkanes (nC_{27} to nC_{33}) and are typically associated/observed with inputs from terrestrial run-off (leaf waxes, etc., discussed previously). The CPI for the nC_{12} to nC_{36} n-alkanes ranged from 1.81 at station EBSHH_08 to 2.13 at station EBSHH_07 with a mean value of 1.95, suggesting the influence of odd-chain length n-alkanes and biogenic material. Interstation variation across the Hammerhead survey area was low (RSD 5 %). The mean Hammerhead CPI value was comparable to the CPI value mean recorded at the Payara development (2.22; Fugro, 2019a).

The isoprenoidal alkanes pristane (Pr) and phytane (Ph) were reported in low concentrations in each of the sediment samples analysed. These compounds are present in significant concentrations in crude oils (Berthou and Friocourt, 1981). They may also be biosynthesised (Gunkel and Gassmann, 1980) and pristane, a breakdown product of the phytol moiety of chlorophyll is widespread in the marine ecosystem, probably being derived from zooplankton. Phytane is generally absent or present in only relatively low levels in uncontaminated natural systems (Blumer and Snyder, 1965). The Pr/Ph ratios reported in the sediments ranged from 0.92 at station EBSHH_02 to 1.58 at station EBSHH_03, with a mean value of 1.25 (Table 5.1). These values would typically suggest that the higher proportion of the pristane present in the sediments was derived from non-petrogenic sources.

10.3.2 Aromatic Hydrocarbons

Polycyclic aromatic hydrocarbons (PAHs) and their alkyl homologues have been detected in a wide range of marine sediments (Youngblood and Blumer, 1975; Laflamme and Hites, 1978; Neff, 1979). These compounds consist of two or more fused benzene rings in linear, angular or cluster arrangements. Polycyclic aromatic hydrocarbons technically contain only carbon and hydrogen atoms. However, other atoms (e.g. nitrogen, sulphur and oxygen) may be readily substituted into the benzene ring to form heterocyclic compounds that are present in significant concentrations in petroleum and refined products.

Monitoring of aromatic hydrocarbon type and content is important due to the particularly toxic nature (mutagenic/carcinogenic) of several PAHs even at very low concentrations. The US EPA has identified 16 priority PAHs to be monitored (Keith, 2015) and the CEMP specifies 9 PAHs of specific concern (OSPAR, 2014), which primarily reflect inputs from anthropogenic combustion sources (further alkylated and parent compounds are normally studied because of the information they provide on PAH origin and fate). Many PAHs have long been recognised as universal environmental pollutants with the heavier molecular weight PAHs (mainly 4 to 6 ring PAH) generally being regarded as carcinogens and mutagens. Indeed, 11 of 40 PAHs ranging from 3 to 6 ring structures have been listed as being strongly carcinogenic or mutagenic with a further 10 listed as weakly carcinogenic or mutagenic (Edwards, 1983).

As previously stated, PAHs are widely spread in the environment (Butler et al., 1984) with natural sources occurring primarily through synthesis by plants (Neff, 1979; Sims and Overcash, 1983), related to natural seeps of petroleum (NRC, 1983; Kennicutt et al., 1988) and to formation during natural forest and prairie fires (Youngblood and Blumer, 1975; Wakeham et al., 1979). By far the greatest proportion of PAHs released into the environment are formed during fossil fuel combustion and anthropogenic forest and agricultural fires (Edwards, 1983; Sims and Overcash, 1983). Once released into the atmosphere PAHs may be carried long distances adsorbed to particulate material (e.g. soot and fly ash; Windsor and Hites, 1979). Similarly, when deposited within the water environment PAHs may undergo further transport (e.g. by rivers or ocean currents) before final deposition in the sediments. Due to the low solubility and hydrophobic nature of PAHs, when deposited within the water column they tend to be adsorbed to suspended inorganic and organic particulate matter, which gradually settles out. Once deposited in the sediment PAHs are less susceptible to photochemical and biological degradation and may accumulate to relatively high concentrations.

Petroleum sources are rich in aromatic hydrocarbons, particularly 1 to 3 ring compounds (benzenes, naphthalenes and phenanthrenes); the levels of 4 to 6 ring compounds being relatively low. In addition, significant concentrations of organosulphur compounds (dibenzothiophenes) are normally present (Friocourt et al., 1982). The relative proportion of these compounds will vary between crude oils and refined petroleum.

The many possible origins of PAHs in marine sediments have been briefly discussed in this section. The source of the PAHs may be determined by investigation of the relative proportions of individual PAH concentrations (Neff, 1979; Garrigues et al., 1995; Budzinski et al., 1997) as well as examining the overall distributions of parent and alkylated PAHs present. Pyrogenically (or pyrolytic) derived PAHs signatures (i.e. forest fires, etc.) are dominated by higher molecular weight compounds (mainly 4 to 6 ring) and are predominantly unsubstituted. In contrast, PAH formed during the slow geological maturation of petroleum, are dominated by alkylated, low molecular weight (mainly 1 to 3 ring) compounds (Neff, 1979).

Most natural and anthropogenic contaminants have a higher affinity to fine particulate matter than coarse sediments, due to the increased adsorption capacity of organic matter and clay minerals. Natural sediment contaminant concentrations will be closely related to the distribution of fine grained material with the effects of other sources of contaminants, for example anthropogenic sources, at least partly obscured by sediment characteristics (ICES, 2009; 2012). PAHs are lipophilic and bind strongly to organic matter in sediments (Davies, 2004).

The potential environmental effects of 2 to 6 ring PAH compounds present were assessed by comparisons with available comparable environmental data. The PAH concentrations can be directly compared with their assigned ERL and ERM threshold values where available (Table 10.1 and Figure 10.2;).

Figure 10.2: Comparison of sediment 2 to 6 ring aromatic hydrocarbons concentrations with regional/background data sets, Hammerhead development

Total 2 to 6 ring PAH concentrations ranged from 0.034 µg/g to 0.064 µg/g with a mean concentration of 0.047 µg/g (Table 5.2). In order to assess the potential environmental effects, these concentrations were compared to available regional data (Tables 5.2 and 10.1) and assigned NOAA ERL and ERM thresholds (Buchman, 2008), (Table 10.1 and Figure 10.2). The mean total 2 to 6 ring PAH concentration recorded at the Hammerhead development was higher than the mean recorded at the Payara development (0.0018 µg/g; Fugro, 2019a) but comparable to those recorded at the Liza field (0.048 µg/g; Fugro, 2016). For the US EPA 16 compounds assessed, the mean concentrations reported within the Hammerhead survey area were below the NOAA ERL and ERM threshold concentrations (Buchman, 2008). Consequently, it is unlikely that the PAH concentrations present in the Hammerhead sediments would have a detrimental effect on the marine macrofaunal community.

10.4 Sediment Metals

10.4.1 Heavy and Trace Metals

The analysis of samples for heavy metal content can provide further corroboration in conjunction with the physical characteristics and hydrocarbon content of marine sediments in assessing either the background levels or the dispersion of discharged material around offshore installations.

Metals and metalloids occur naturally in the marine environment and are widely distributed in both dissolved and sedimentary forms. Some are essential to marine life while others have no biological function and therefore are toxic to numerous organisms at certain levels (Paez-Osuna and Ruiz-Fernandez, 1995; Boening, 1999). Metals can enter the environment via natural methods such as riverine transport, coastal discharges, geological weathering and atmospheric fallout (Brady et al., 2015). Other routes into marine sediments are from anthropogenic activities such as direct discharges from industrial activities.

Trace metal contaminants in the marine environment tend to form associations with the non-residual phases of mineral matter, such as iron and manganese oxides and hydroxides, metal sulphides, clays, organics and carbonates (Warren and Zimmerman, 1993; Dang et al., 2015; Wang et al., 2015). Non-residual trace metals are associated with more reactive and available sediment components through processes such as adsorption onto mineral surfaces and organic complexation. Metals associated with these more reactive phases are prone to various environmental interactions and transformations (physical, chemical and biological) potentially increasing their mobility and biological availability (Tessier et al., 1979; Warren and Zimmerman, 1993; Du Laing et al., 2009). Residual trace metals are defined as those which are part of the crystal structure of the component minerals and are generally unavailable to organisms (de Orte et al., 2018). Therefore, in monitoring trace metal contamination of the marine environment, it is important to distinguish the more mobile non-residual trace metals from the residual metals held tightly in the sediment lattice (Chester and Voutsinou, 1981), which are of comparatively lesser environmental significance because of their low reactivity and availability.

In this study, an analytical procedure involving the digestion of sediment in aqua regia was employed to analyse the elemental content of the sediments. The aqua regia digest releases for analysis the ‘non-residual’ heavy metals, which are not incorporated in the mineral matrix and are therefore potentially available for biological uptake.

All bioavailable metals concentrations in the sediments within the Hammerhead survey area exhibited low interstation variability across the survey area (RSD ≤ 21 %; Table 6.1). Despite the low variability, metals concentrations were generally lowest at station EBSHH_07 and highest at station EBSHH_02.

Mean metals concentrations were generally higher within the Hammerhead development in the current study than reported within the Payara development in 2018 (Fugro, 2019a), with the exception of arsenic (Table 10.2). The mean arsenic concentration reported in 2018 was elevated largely due to one outlier and featured high interstation variability (Figure 10.3). Arsenic concentrations reported within the current survey are broadly comparable to the majority of arsenic concentrations reported within the Payara development in 2018 (Fugro, 2019a).

The metals of biological interest were compared against their respective NOAA ERL and ERM values (Buchman, 2008). Metals concentrations were generally below NOAA ERL levels (Buchman, 2008), with the exception of arsenic and nickel, which exceeded their respective ERL values at the majority of stations (Table 6.1, Figure 10.3). No metals concentrations exceeded NOAA ERM levels (Buchman, 2008).

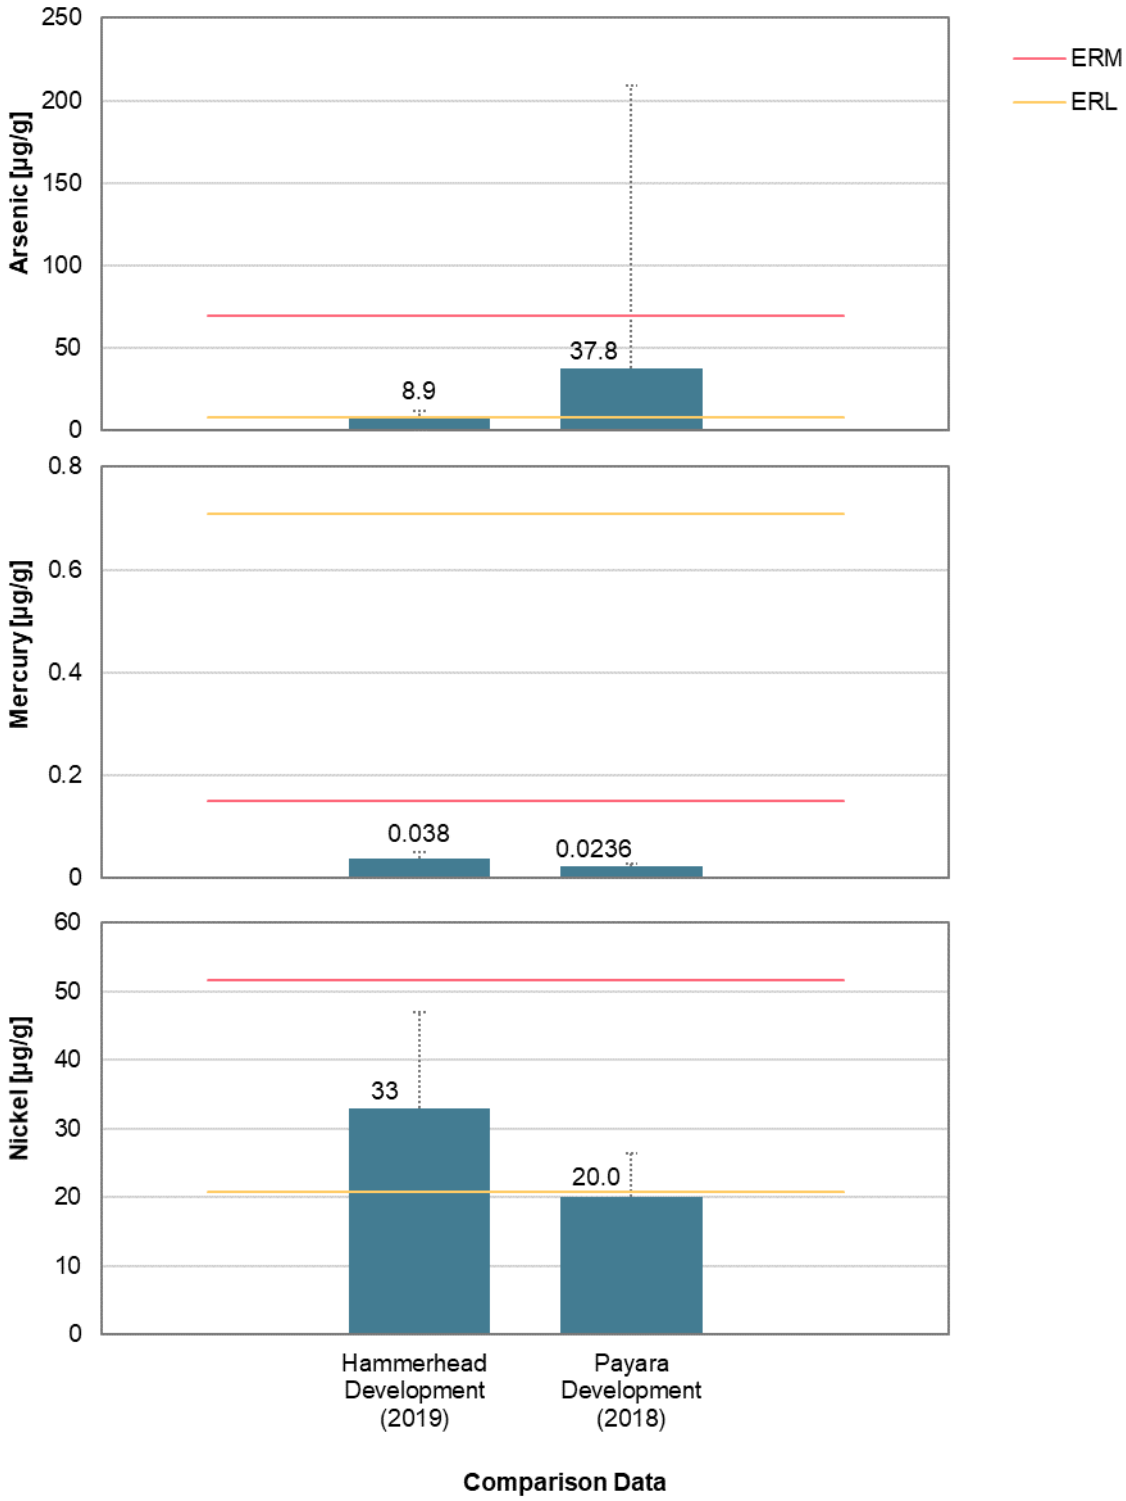
Metals could be, in part, introduced from contaminated terrestrial runoff from Guyana's mining industry via the main riverine inputs to the Guyana basin (TDI Brooks, 2014). Arsenic is a known by-product of gold mining, which is a key industry in Guyana. Arsenic enriched sediments, possibly related to gold mining, were previously observed in the region at the Liza field in 2016 and the Payara development in 2018 (Fugro, 2016; 2019a). Other potential sources of arsenic into the marine sediments are from geogenic sources, as arsenic is known to originate from arsenic bearing minerals such as arsenopyrite. The elevated concentrations of arsenic in this survey, as within the Payara development in 2018, coincide with higher concentrations of iron and such minerals can be transported to marine sediments from riverine discharges into the Atlantic.

If NOAA ERL and ERM values are exceeded, there is a higher probability that sediment quality will be impaired and impact the benthic community. However, elevated concentrations of both arsenic and nickel have been reported elsewhere within the region, with no observed impact on the macrofaunal community. For example, within the Payara development in 2018, reported concentrations were comparable to the current study and approached or exceeded the ERL values (Fugro, 2019a). Correlation analysis provided no indication, within the current survey or within the Payara development in 2018, that the metals concentrations reported influence the sediment macrofauna within this region. Consequently, there is unlikely to be any negative impact on the macrofaunal community from the concentrations of metals present in the sediment.

Table 10.2: Comparison of Sediment Metals Concentrations with Background and Reference Values, Hammerhead Development

Parameter	Hammerhead Development (2019) Mean	Payara Development (2018) Mean	Marine Sediment Assessment Criteria (Buchman, 2008)	
Aqua Regia Digest			**ERL**	**ERM**
Arsenic	8.9	37.8	**8.20**	**70.0**
Cadmium	0.14	-	**1.20**	**9.60**
Chromium	50	30.3	**81.0**	**370**
Copper	17	15.1	**34.0**	**270**
Mercury	0.038	0.0236	**0.150**	**0.710**
Nickel	33	20.0	**20.9**	**51.6**
Lead	19	12.3	**46.7**	**218**
Zinc	85	60.5	**150**	**410**

Notes:
Concentrations expressed in µg/g dry weight
ERL = Effects range low
ERM = Effects range median



Notes:
Error bars represent 95th percentile
Hammerhead development (2019) = Mean of current survey in Hammerhead development survey area
Payara development (2019a) = Mean of in the neighbouring Payara development in 2018 (Fugro, 2019a)
ERL/ERM = Effects range low/median (Buchman, 2008)
Hammerhead development (2019) = Mean estimated from current survey data
Payara development (2018) = Mean estimated from an environmental survey in the neighbouring Payara development in 2018 (Fugro, 2019a)

Figure 10.3: Comparison of sediment arsenic, mercury and nickel concentrations (means) with regional/background data sets, Hammerhead development

10.5 Water Samples

10.5.1 Water Profiles

Water column profile results from all stations displayed a defined thermocline, halocline, pH boundary and oxygen boundary. Surface temperatures were comparable between stations, decreasing with water depth, a thermocline was present at approximately 400 m at all stations. Turbidity results were constant throughout the water column.

Salinity was generally lowest at the sea surface, likely to be influenced by precipitation and freshwater input from the Essequibo River in Guyana. A distinct halocline was observed at approximately 200 m, after which salinity remained at approximately 35.0 PSU.

The oxygen content of natural waters varies with temperature, salinity, turbulence, the photosynthetic activity of algae and plants, and atmospheric pressure. Biological respiration, including that related to decomposition processes, reduces dissolved oxygen concentrations. The solubility of oxygen decreases as temperature increases. Dissolved oxygen decreases with an increase in salinity. Dissolved oxygen saturation ranged from 33.4 % near the seabed to 108 % near the surface, demonstrating that surface waters within the survey area were at near oxygen saturation, at the time of survey, with no indication of oxygen depletion.

At all water sampling stations, the pH decreased slowly with increasing depth. The US EPA quote a normal range for seawater as pH 6.5 to 8.5 (US EPA, 2018) and the seawater pH values for the current survey conform to this range.

10.5.2 Nutrients and Total Suspended Solids (TSS)

In water the forms of nitrogen that are of most interest are nitrate, nitrite, ammonia and organic nitrogen. Nitrate is the final oxidation product of nitrogen compounds in seawater and is considered the most thermodynamically stable oxidation level under aerobic conditions; it is one of the most important nutrients controlling primary production. Nitrite forms the intermediate between the reduction of nitrate and the oxidation of ammonia in sea and estuarine water. The concentrations of nitrite are typically low except in transition zones between oxic and anoxic conditions (Mordy et al., 2010). In oxygenated natural water systems, nitrite is rapidly oxidised to nitrate and consequently, concentrations of nitrite would be expected to be low.

The concentrations of the various chemical parameters measured in the water samples collected in the Hammerhead survey area were low, with both nitrite and TKN concentrations below the MRV throughout indicating that there is no notable anthropogenic pollution present in the survey area. Little evidence of stratification was demonstrated, with the mean concentrations of reported nitrogen compounds broadly comparable at all sampled depths.

Total suspended solids are important indicators of water quality and can be indicative of sediment transport and discharge from drilling activities. No evidence of stratification was present for the Hammerhead water column samples, suggesting a well-mixed distribution of TSS throughout the water column. The mean TSS values in the current survey were higher than those from the Payara development (Fugro, 2019a) and the Liza field survey (Fugro, 2016) at comparable depths. There are large seasonal variations in suspended particulate matter and the current survey was conducted during

the rainy season, potentially accounting for the higher suspended solids content due to increased riverine discharges from the Amazon River (Martinez, et al. 1999). TSS content in the Hammerhead water column is likely to originate from the northward movement of suspended material from the Amazon River and other major rivers that discharge into the Atlantic (Pujos and Froidefond, 1995).

TOC consists of both dissolved and particulate organic carbon and can be an approximate indicator of productivity in marine waters where anthropogenic inputs are not present. The mean TOC values observed at the Hammerhead development were comparable at different depths suggesting no evidence of stratification. The mean TOC values observed were higher than those recorded at the Payara development (Fugro, 2019a), but lower than the mean values recorded at the Liza field survey (Fugro, 2016).

10.5.3 Hydrocarbons

Hydrocarbon content can be used as an indicator of petrogenic inputs into water columns. This is because soluble fractions of hydrocarbons can partition between dissolved and particulate bound phases in the water column (Latimer and Zheng, 2003; Thibodeaux et al., 2011). THC and PAH levels were generally low and therefore considered to be representative of background concentrations.

10.5.4 Metals

Heavy and trace metal concentrations were low in most water samples, being close to or below their respective MRVs in the majority of samples across the Hammerhead development. Metals concentrations were broadly comparable to those reported previously in the region, in the Liza field and the Payara development (Fugro, 2016; 2019a). No metals concentrations exceeded the US EPA CCC or CMC values (US EPA, 2018). Consequently, the metals concentrations within the water samples are unlikely to negatively impact the benthic or pelagic biota.

No trends were observed between metals concentrations and depth in the Hammerhead water samples.

10.6 Seabed Habitats

The ‘Biotopes/Ecosystems Nomenclature, Habitats of South America’ (Institute of Terrestrial Ecology, 1996) allowed the Hammerhead survey area to be broadly split in to two biotope complexes: ‘Sublittoral soft seabeds (11.22) observed on drop-down video stations and ‘Deep-sea floor” (11.21) observed on transects TR01 to TR06.

More detailed habitat classifications were assigned to the survey area using the EUNIS (2012) classification system. Areas of low sonar reflectivity, assigned ‘Sublittoral soft seabeds (11.22) (Institute of Terrestrial Ecology, 1996), corresponded with the level three EUNIS (2012) classification of ‘Sublittoral mud’ (A5.3). The Institute of Terrestrial Ecology (1996) habitat classification of ‘Deep-sea floor” (11.21), assigned to areas with gravelly, muddy sand and elevated exposed seabed was further split in to two EUNIS habitat classifications. Gravelly, muddy sand sediments where epifaunal diversity and abundance was low, were classified ‘Deep-sea muddy sand’ (A6.4), although epifauna communities were sparse pencil urchins (Cidaridae), small unidentified fish (Pisces), sea cucumber (Holothuroidea) and starfish (Asteroidea) were occasionally observed; bioturbation in the form of faunal holes was recorded, suggesting an active infaunal community. The EUNIS (2012) classification of ‘deep-sea rock and artificial hard substrata’ (A6.1) was assigned to elevated, exposed bedrock; epifaunal community

comprised predominantly of sessile taxa such as sponges (Porifera), sea fan (Gorgoniidae), sea whip (Octocorallia), black coral (Antipatharia), wire coral (*Stichopathes* sp.) and stony coral (Scleractinia). Epifaunal abundance and diversity increased in areas where hard substrate was prevalent.

10.7 Macrofaunal Communities

Seabed sediments provide support, protection and the food source for many macrofaunal species. The sediment macrofauna, most of which are infaunal (living within the sediment), are therefore particularly vulnerable to external influences which alter the sediments' physical, chemical or biological nature. Such infaunal animals are largely sedentary and are thus unable to avoid unfavourable conditions. Each species has its own response and degree of sensitivity to changes in the physical and/or chemical environment and consequently the species composition and their relative abundance in a particular location provides a reflection of the health and condition of the immediate environment, both current and historical. The recognition that aquatic contaminant inputs may alter sediment characteristics, together with the relative ease of obtaining quantitative samples from specific locations, has led to the widespread use of infaunal communities in monitoring the impact of disturbances to the marine environment over a long period of time.

Phyletic composition of the macrofaunal community within the Hammerhead development was broadly comparable to previously reported macrofaunal communities within the area, with arthropods, annelids and molluscs consistently the most diverse and abundant phyla in surveys within the area, and echinoderms and other phyla reported at relatively low abundance and diversity (Table 10.3). Peanut worms (Sipuncula), ribbon worms (Nemertea) and taxa within the phylum Cnidaria are frequently reported within the other phyla within the area. The phyletic composition reported within the current survey is typical of deep-sea macrofaunal communities, which are generally dominated by annelids, followed by small-bodied arthropods and molluscs. Polychaetes typically comprise more than a third of the number of taxa and approximately half of the number of individuals in sedimentary deep-sea communities (Gage and Tyler, 1991).

Due to the low abundance of all taxa, the characteristic taxa varied between stations. Across the survey area the molluscs *Ennucula* and *Microgloma mirmidina* and those of the class Caudofoveata, the arthropods *Typhlotanais*, and those of the family Desmosomatidae, the annelids *Ophelina* and *Fauveliopsis*, the brittlestar *Ophiotholia* and the peanut worms *Aspidosiphon* (*Akrikos*) *zinni* and *Phascolosoma*? were the most abundant. Several other locally abundant taxa were identified, including the arthropod *Apseudes* sp. B and the annelid *Aricidea.* Despite the heterogeneity across the survey area, all characteristic taxa are typical of sedimentary deep-sea environments.

Paraonidae (e.g. *Aricidea*) is one of the most abundant polychaete families in sedimentary deep-sea communities. Opheliidae (e.g. *Ophelina*) and Cirratuliformia (e.g. *Fauveliopsis*) are also typical. Bivalves are the most abundant molluscs within deep-sea habitats, with the Nuculidae (e.g. *Ennucula* and *Microgloma mirmidina*) prominent (Gage and Tyler, 1991). The dominance of bivalves over gastropods within the current survey reflects the high fines content of the sediment recorded at all stations (≥ 67.8 %). Tanaids and isopods are extremely diverse within the deep-sea, in comparison to shallower waters. Within the tanaids, this is particularly true for those in the suborder Tanaidomorpha (e.g. *Typhlotanais*), with the larger suborder Apseudomorpha (e.g. *Apseudes* sp. B) more rarely represented, featuring elevated abundance with greater depth (Gage and Tyler, 1991). The worm-like

mollusc Aplacophora (e.g. Caudofoveata) and the phylum Sipuncula (e.g. *Aspidosiphon* (*Akrikos*) *zinni* and *Phascolosoma*?) are often relatively abundant in the deep-sea (Gage and Tyler, 1991). Within deep-sea communities, errant megafauna are generally dominated by the echinoderms, with brittlestars of the class Ophiuroidea (e.g. *Ophiotholia*) amongst the most commonly reported.

Table 10.3: Taxonomic Groups, Hammerhead Development and Historical Comparable Data

Taxonomic Group	Hammerhead Development (Current Survey)*	Payara Development (Fugro, 2019a)†	Liza Field (Fugro, 2016)‡
Composition of Taxa [%]			
Annelida	32.9	35.6	40.0
Arthropoda	40.7	39.0	38.2
Mollusca	18.6	16.9	12.7
Echinodermata	3.6	3.4	3.0
Other phyla	4.3	5.1	6.0
Composition of Individuals [%]			
Annelida	27.7	51.0	42.7
Arthropoda	34.0	30.3	39.1
Mollusca	26.0	9.0	8.7
Echinodermata	4.6	2.6	1.6
Other phyla	7.8	7.1	7.9

Notes:
* = Other phyla include: Cnidaria, Nemertea and Sipuncula
† = Data from an environmental survey in the neighbouring Payara development in 2018, in depths of ca. 1800 m to ca. 2100 m. 0.2 m^2 stations processed through a 0.5 mm sieve. Other phyla included: Sipuncula (Fugro, 2019a)
‡ = Data from an environmental survey in the neighbouring Liza field in 2016, in depths of ca. 500 m to ca. 2800 m. 0.1 m^2 stations processed through a 0.5 mm sieve. Other phyla include: Cnidaria, Nemertea and Echiura (Fugro, 2016)
Macrofaunal samples were processed through a 0.5 mm sieve in all surveys

Univariate analysis indicated that diversity was high across the survey area (mean H'Log^2 4.88; Dauvin et al., 2012), higher than reported in slightly deeper waters within the Payara development in 2018 (Fugro, 2019a) and from a wide depth range in the Liza field in 2016 (Fugro, 2016). Evenness was also high indicating that faunal abundances were evenly distributed across the taxa recorded. The mean Pielou's evenness index reported in the current survey was broadly comparable to that reported from the Liza field in 2016 and within the Payara development in 2018 (Fugro, 2016; 2019a). Deep-sea macrofaunal communities generally feature high taxonomic diversity (Gage and Tyler, 1991).

There was a low to moderate degree of faunal similarity across the Hammerhead development survey area, with stations clustering with between 19.3 % and 37.4 % similarity. Such similarities are likely due to the number of taxa reported at low abundance, often as a single specimen within the survey area. When untransformed data was considered, two statistically significant clusters were apparent, with the macrofaunal community at the two shallowest stations (stations EBSHH_07 and EBSHH_08 in water depths of < 800 m) significantly different to that at the remaining six deeper stations.

Table 10.4: Comparison of the Top Ten Most Abundant Taxa in the Region

Hammerhead Development (Current Survey)	Payara Development (Fugro, 2019a)*	Liza Field (Fugro, 2016)†
Ennucula	*Spiophanes*	*Spiophanes* (dam.)
Desmosomatidae	Balanidae sp. A	*Myriochele*
Typhlotanais	Oweniidae	Ampeliscidae
Ophiotholia	*Bathyglycinde profunda*	Ampharetidae (dam.)
Aspidosiphon (Akrikos) zinni	***Aspidosiphon zinni***	*Glabroapseudes*
Phascolosoma?	*Kirkegaardia*	*Monticellina*
Ophelina	Ampeliscidae	**Desmosomatidae**
CAUDOFOVEATA	*Paradoneis*	*Harpinia* sp. A
Fauveliopsis	Five other taxa including *Collettea*, Ophiuridae sp. A, *Heteromesus*, **Opheliidae**, Cirratulidae	*Leptanthura affinis*
Microgloma mirmidina		***Aspidosiphon zinni***

Notes:
* = Top ten taxa from an environmental survey in the neighbouring Payara development in 2018, in depths of ca. 1800 m to ca. 2100 m. 0.2 m^2 stations processed through a 0.5 mm sieve (Fugro, 2019a)
† = Top ten taxa from an environmental survey in the neighbouring Liza field in 2016, in depths of ca. 500 m to ca. 2800 m. 0.1 m^2 stations processed through a 0.5 mm sieve. Number of taxa, diversity and evenness indices presented as original data. Number of individuals per 0.2 m^2 estimated from 20 per 0.1 m^2 and presented for comparison (Fugro, 2016)
Bold = taxa reported in the current survey and at least one previous survey

Multivariate statistics highlighted that differences in the macrofaunal community were largely reflective of marginally increased abundance of several taxa within shallower stations, and the presence or absence of taxa associated with different depth ranges. For example, tanaid arthropods (particularly *Apseudes* sp. A) were present in higher abundance at the majority of stations sampled in deeper waters (> 800 m). Additionally, several bivalve molluscs (e.g. *Ennucula* and *Ledella pustulosa* and those of the family Veneroidea sp. A) were reported from shallower stations but were absent (or present at low abundance) from deeper stations. As discussed above, all these taxa are typical of deep-sea communities, with bivalves generally favouring sedimentary habitats.

Despite the differences suggested in the macrofaunal community with depth in preceding sections of this report, depth was not significantly correlated with any macrofaunal parameters. As previously mentioned, no significant correlations were demonstrated between macrofaunal parameters and the physical or chemical parameters. This is in part due to the low interstation variability in the majority of parameters across the survey area. The mean particle size was highest at shallower stations EBSHH_07 and EBSHH_08 (Table 4.1), where the highest proportions of sand were also reported (Table 4.2). Consequently, it is likely that the differences observed in the macrofaunal community are the result of small differences in one or several parameters associated with depth rather than depth itself (e.g. natural sediment characteristics).

11. CONCLUSIONS

The aim of this report has been to evaluate the existing physical/chemical components in the marine environment within the survey area. A review of the environmental data in context with other cited studies from the region and estimated sediment effects threshold values (US EPA, 2018, Buchman, 2008) was also undertaken. Based on the overall assessment of the survey area, the following key conclusions can be stated:

The sediments across the Hammerhead survey area were all classed as very poorly sorted, with the exception of station EBSHH_04 which was described as poorly sorted, sediment composition was primarily fines and sands. Using the Wentworth (1922) sediment description, five stations were classified as ‘fine silt’, two were classified as ‘very fine silt’ and one station was classified as ‘medium silt’.

The gas chromatographic profiles obtained from sediments collected from within the Hammerhead survey area were typical of background sediments, displaying weathered low-level petroleum and biogenic hydrocarbons and associated UCM, commonly found in marine sediments. The total 2 to 6 ring PAH concentrations were low across the survey area, with the United States Environmental Protection Agency’s 16 priority PAH pollutants (US EPA 16 PAH) below their respective ERL values at all stations.

All bioavailable metals concentrations in the sediments within the Hammerhead survey area exhibited low interstation variability across the survey area (RSD ≤ 21 %). Metals concentrations were generally below the NOAA ERL threshold, with the exception of arsenic and nickel, which exceeded their respective ERL values at the majority of stations. No metals concentrations exceeded the NOAA ERM thresholds. Despite arsenic and nickel exceeding their respective ERL values, both metals were reported in concentrations that were comparable to available regional data and thus are considered typical of the region.

Water profiles showed a stratified water column, with a defined thermocline, halocline and oxygen boundary down to ca. 400 m, after which values remained relatively constant. Turbidity remained constant throughout the profile.

The nitrogen compounds, TOC and TSS values derived from the Hammerhead water samples showed no evidence of stratification as the mean values for all parameters for each depth profile were comparable.

Water sample THC and PAH concentrations across the survey were low and values were indicative of background concentrations. There were no clear spatial trends in concentrations of the hydrocarbon parameters across the survey area and no clear relationship between concentrations of these analytes and depth.

The metals concentrations reported in water samples within the Hammerhead development were low, with the majority of metals present in concentrations close to or below their respective MRVs. No metals concentrations exceeded their respective US EPA CCC or CMC values (US EPA, 2018). No spatial or depth patterns were observed. As such, the metals concentrations within the water samples are unlikely to negatively impact the benthic or pelagic biota.

Analysis of the photographic data allowed the Hammerhead survey area to be split in to two broad habitats in accordance with 'Biotopes/Ecosystems Nomenclature, Habitats of South America' (Institute of Terrestrial Ecology, 1996). 'Sublittoral soft seabeds' (11.22) and 'deep-sea floor' (11.21). The EUNIS (2012) classification allowed these habitats to be further split in to three distinct habitats: Areas designated 'Sublittoral soft seabeds (11.22) (Institute of Terrestrial Ecology, 1996) corresponded with fine sediments and were assigned the level three EUNIS (2012) classification of 'sublittoral mud' (A5.3). Areas assigned 'deep-sea floor" (11.21) (Institute of Terrestrial Ecology, 1996) were further spilt into two separate habitats: 'deep-sea muddy sand' (A6.4) defined areas with gravelly, muddy sand sediments with low epifaunal diversity and abundance. 'Deep-sea rock and artificial hard substrata' (A6.1) defined elevated, exposed bedrock with higher epifaunal diversity and abundance.

Within the faunal community present at the Hammerhead survey area, arthropods were the most diverse and abundant phyla, followed by annelids and then molluscs, this is similar to the faunal communities previously recorded at the Payara development (Fugro, 2019a) and the Liza field (Fugro, 2016).

Univariate analysis demonstrated that although abundance of all taxa was low, macrofaunal diversity was high. Multivariate statistics highlighted that differences in the macrofaunal community were largely reflective of a marginally elevated abundance of several taxa within shallower stations, and the presence or absence of taxa associated with different depth ranges. The differences in the macrofaunal community are likely driven by small differences in the sediment characteristics associated with depth rather than depth itself, with the macrofaunal community across the survey area typical of deep-sea sedimentary habitats.

No meaningful correlations were observed between the macrofaunal community and the rest of the physico-chemical parameters sampled across the Hammerhead survey area.

Overall, the environmental data obtained from the Hammerhead survey area is typical of background conditions.

A. GUIDELINES ON USE OF REPORT

This report (the “Report”) was prepared as part of the services (the “Services”) provided by Fugro GB Marine Limited (“Fugro”) for its client (the “Client”) under terms of the relevant contract between the two parties (the “Contract”). The Services were performed by Fugro based on requirements of the Client set out in the Contract or otherwise made known by the Client to Fugro at the time.

Fugro’s obligations and liabilities to the Client or any other party in respect of the Services and this Report are limited in time and value as defined in Contract (or in the absence of any express provision in the Contract as implied by the law of the Contract) and Fugro provides no other representation or warranty whether express or implied, in relation to the Services or for the use of this Report for any other purpose. Furthermore, Fugro has no obligation to update or revise this Report based on changes in conditions or information which emerge following issue of this Report unless expressly required by the Contract.

The Services were performed by Fugro exclusively for the Client and any other party identified in the Contract for the purpose set out therein. Any use and/or reliance on the Report or the Services for purposes not expressly stated in the Contract, by the Client or any other party is that party’s risk and Fugro accepts no liability whatsoever for any such use and/or reliance.

B. METHODOLOGIES

B.1 LABORATORY ANALYSIS - SEDIMENTS

B.1.1 Particle Size Analysis (PSA)

Particle size analysis (PSA) was conducted by Fugro GB Marine Limited (FGBML).

B.1.1.1 Dry Sieve Analysis

Particle size distribution (PSD) analysis was undertaken in accordance with FGBML in-house methods based on the National Marine Biological Association Quality Control scheme's (NMBAQC) best practice guidance document – Particle Size Analysis (PSA) for Supporting Biological Analysis, and BS1377: Parts 1: 2016 and 2: 1990.

Representative material > 1 mm was split from the bulk subsample and oven dried before sieving through a series of sieves with apertures corresponding to 0.5 phi intervals between 63 mm and 1 mm as described by the Wentworth scale (Wentworth, 1922). The weight of the sediment fraction retained on each mesh was subsequently measured and recorded.

B.1.1.2 Laser Diffraction

Particle size distribution (PSD) analysis was undertaken in accordance with FGBML in-house methods based on the NMBAQC best practice guidance document – Particle Size Analysis (PSA) for Supporting Biological Analysis, and BS ISO 13320: 2009.

Representative material < 1 mm was removed from the bulk subsample for laser analysis, a minimum of three triplicate analyses (mixed samples) or one triplicate analyses (sands) were analysed using the laser sizer at 0.5 phi intervals between < 1 mm to < 3.9 µm. Laser diffraction was carried out using a Malvern Mastersizer 2000 with a Hydro 2000G dispersion unit.

B.1.2 Total Organic Carbon (TOC)

Sediment samples were analysed for total organic carbon (TOC) by Exova Jones Environmental.

The dry, homogenised sample was treated with hydrochloric acid, then rinsed with deionised water to remove mineral carbon. The sample was then combusted in an Eltra TOC furnace/analyser in the presence of oxygen. Organic carbon was oxidised to CO_2 and measured by non-dispersive infrared analysis. This method does not quantify volatile organic carbon, which should be determined by another technique. The minimum reporting value (MRV) for this method was < 0.02 % w/w.

B.1.3 Hydrocarbon Analysis in Sediments

Hydrocarbon analysis of sediments was carried out by FGBML.

B.1.3.1 General Precautions

To effectively eliminate all possible sources of hydrocarbon contamination from the analysis the following precautionary measures were taken prior to sample work-up:

- All solvents were purchased as high purity grade. Each batch was checked for purity by concentrating approximately 400 mL down to a small volume (< 1 mL) and analysing by gas chromatography (GC);
- All water used was distilled through an all glass still and dichloromethane extracted to minimise contamination from plasticisers;
- All glassware was cleaned using an acid/base machine wash. The glassware was rinsed with acetone then finally with dichloromethane prior to use;
- Procedural blanks, replicate analyses and laboratory reference material were run with each batch.

B.1.3.2 Ultrasonication Extraction for Hydrocarbons in Sediment

Sediment samples were thawed, homogenised and accurately weighed into a 250 mL conical flask. A solution containing an appropriate amount of the following internal standards was added to each sample using a microsyringe.

Aliphatic Standards	Aromatic Standards
Heptamethylnonane	D_8 naphthalene
D_{34} Hexadecane	D_{10} acenaphthene
D_{42} Eicosane	D_{10} phenanthrene
Squalane	D_{10} pyrene
	D_{12} chrysene
	D_{12} perylene

Methanol (50 mL) and solvent were mixed with the sediment. Dichloromethane (DCM) (60 mL) was then added and the sample mixed again. The flasks were then capped with solvent cleaned aluminium foil and ultrasonicated for 30 minutes.

After being allowed to settle the solvent was decanted through a GF-C filter paper into a 1 litre separating funnel. The extract was then partitioned with 100 mL of DCM extracted distilled water and the DCM layer run-off into a clean 500 mL round-bottomed flask. The ultrasonic extraction was repeated a further two times using 50 mL DCM and 15 minutes of ultrasonication. Each time the filtered extract was partitioned with the remaining methanol/water in the separating funnel. The DCM extracts were bulked and reduced in volume to approximately 2 mL using a rotary evaporator, then further reduced to approximately 1 mL under a gentle stream of nitrogen prior to clean-up.

Correction factors for wet/dry sediments were obtained by drying a subsample of the homogenised sediment to constant weight at 105 °C.

B.1.3.3 Clean-up of Extracts by Column Chromatography

Removal of polar material, including lipids was carried out using a silica gel column. The silica gel used was 70 to 230 mesh which was heated at 400 °C for at least 4 hours to remove impurities and residual moisture and then stored at 200 °C prior to use. The sample extract was added to the silica gel column, containing 5 g of adsorbent and eluted with 35 mL of DCM/pentane (1:2). The eluant was reduced in volume using the evaporator to approximately 2 mL, with activated copper powder (for removal of free sulphur), before being further reduced under a gentle stream of nitrogen to an appropriate volume and analysed by both gas chromatography (GC) and gas chromatography-mass spectrometry (GC-MS).

Instrument	Gas Chromatography [GC]	Gas Chromatography-Mass Spectrometry [GC-MS]
	HP 6890 Series GC with 7673 autoinjector	HP 7890 Series GC with autoinjector and 5977A MSD
Column	100 %-dimethylpolysiloxane bonded fused silica, 60 m, 0.25 µm film thickness, 0.32 mm internal diameter	(5 %phenyl)-methylpolysiloxane bonded fused silica, 60 m, 0.32 µm film thickness 0.25 mm internal diameter
Carrier Gas	Hydrogen (constant flow 3.5 mL /min)	Hydrogen (constant flow 1.4 mL/min)
Injector	On–column (2 µL injection)	Splitless, 280 °C, split flow 40 mL/min, vent time 1.5 min (1 µl injection)
Oven Temperature Programme	80 °C – 2 min 80 °C to 320 °C at 18 °C/min 320 °C – 13 min 320 °C to 350 °C at 30 °C/min	60 °C – 1 min 60 °C to 180 °C at 11 °C/min 180 °C to 260 °C at 6 °C/min 260 °C to 320 °C at 6 °C/min 330 °C – 7 min
Source/Detector Temperature	350 °C (FID)	230 °C
Electron Energy	-	70 eV
Selected Ion Monitoring (SIM)	-	9 groups - 6 ions per group
Dwell Time (per ion)	-	0.035 second

B.1.3.4 Total Hydrocarbons by Gas Chromatography–Flame Ionisation Detection (GC-FID)

The total hydrocarbon material present was quantified using response factors calculated from the analysis of mixed oil standard solutions over an appropriate range. The unresolved complex mixture (UCM) was determined by subtracting the area of all the resolved peaks from the total hydrocarbon area and applying the total hydrocarbon response factor.

B.1.3.5 n-Alkanes, Pristane and Phytane

Calibration was undertaken using a range of n-alkane standard solutions containing the even carbon number compounds between nC_{12} and nC_{36}, and a range of suitable internal standards. Individual response factors were calculated for each of the n-alkanes present in the calibration solution. Response factors for the non-calibrated n-alkanes (and pristane and phytane) were taken to be equivalent to closely eluting compounds.

The n-alkanes between nC_{12} and nC_{36} were reported, as were the ranges between nC_{12} and nC_{20} and nC_{21} to nC_{36}. Carbon preference index (CPI) values (the ratio of odd to even carbon numbered compounds) for the same ranges were also calculated. Pristane and phytane (and associated ratio) were also determined.

B.1.3.6 Polycyclic Aromatic Hydrocarbons (PAHs)

A full range of polycyclic aromatic hydrocarbons (PAHs) and alkylated PAH were quantified as specified by Department of Trade and Industry (DTI) regulations (DTI, 1993).

Calibration was undertaken using a range of PAH standard solutions, a number of alkylated PAH, dibenzothiophene and a range of suitable internal standards. Individual response factors were calculated for each of the compounds present in the calibration solution. Response factors for the non-calibrated alkylated PAH were taken to be equivalent to closely related compounds. The MRV of individual PAHs is 0.1 ng/g and 1 ng/g dry weight for alkylated PAHs.

B.1.4 Heavy and Trace Metals in Sediments

Analysis of sediment metals content was conducted by the National Laboratory Service.

Sediment samples were air dried at 30 °C and then sieved to the required size fraction (2000 µm). Samples were subjected to an aqua regia microwave digestion, with the exception of selenium which underwent an aqua regia block digest under reflux. This acid mixture allows a partial dissolution of metals from most soil and sediment types which allows the bioavailable metals content to be analysed. Arsenic, cadmium, chromium, copper, lead, nickel and zinc were analysed by inductively coupled plasma-mass spectrometry (ICP-MS). Aluminium, barium, iron and selenium were analysed by inductively coupled plasma-optical emission spectrometry (ICP-OES).

Mercury content was determined by sieving the sample to < 2000 µm followed by a microwave assisted aqua regia digest, acidic stannous chloride reduction and determination by cold vapour-atomic fluorescence spectroscopy (CV-AFS).

B.1.5 Macrofaunal Analysis

Macrofauna analysis was carried out by FGBML benthic laboratories which are members of the NMBAQC scheme of external quality assurance.

On return to the laboratory, the samples were removed from formalin and washed through 0.5 mm mesh sieves. The material retained was then processed to remove fauna. The animals were separated by hand from the retained sediment by using a combination of stereo microscopes for the fine sediments and in white trays for any coarser material. Processed sediment is stored in phenoxetol (2 %) or returned to the original formalin.

Following extraction, the animals were identified and enumerated by specialist taxonomists. Identification was to species level where possible. Specimens which, due to their immaturity, damage incurred during processing or lack of suitable taxonomic literature, cannot be identified to species level are identified at higher taxonomic levels as appropriate. After identification, samples were stored in 70 % industrial denatured alcohol (IDA) or a mixture of 70 % ethanol/1 % propylene glycol/29 % water. A minimum of 10 % of samples within the project were re-analysed (for extraction, species identification, enumeration and data entry) as per NMBAQC quality control guidelines (Worsfold, 2010). Species abundances were entered on file in a spreadsheet package or the Unicorn database, both of which store and sort entries into taxonomic order and provide output files for numerical analysis. Nomenclature follows that given on the World Register of Marine Species (http://www.marinespecies.org/). The taxonomic order is based on Species Directory codes (Howson and Picton, 1997) to give an idea of ‘evolutionary rank’. Once all the entries had been checked, the resulting quantitative data were subjected to various statistical techniques to investigate community structure. All quantitative analyses were performed on species abundances pooled from the two replicates at each station, thus the sample size was 0.2 m^2 at all stations.

Prior to statistical analysis, the macrofaunal abundance data was manipulated to avoid spurious enhancement of community statistics. This involved the removal of all parasitic (e.g. Copepoda) and damaged (e.g. Sipuncula (dam.)) taxa, as well as juvenile (e.g. Sipuncula (juv.)) specimens, as they are not considered to be a permanent part of the community. Some indeterminate species were also

rationalised at a higher taxonomic level with another taxon in the same genus to maintain these data in the dataset (e.g. *Spiophanes* with Spionidae (dam.)).

B.1.6 Sampling and Analysis Requirements – Sediments

Analyte	Volume per Sample [g]	Sample Container	Fixative/Storage	Analysing Laboratory	Method Code	Method Description	Accreditation	LOD	Holding Time
Al	200	Ziplock bags (double bagged)	Freeze	NLS	IHM 1043	ICP-OES	UKAS	20 µg/g	30 days
As					IHM 1041	ICP-MS		1 µg/g	
Ba					IHM 1043	ICP-OES		0.4 µg/g

PAH (EPA 16/alkylated)					IHM	GC-MS	-	0.1/1 ng/g	
Benthic macrofauna (0.5 mm)	Variable	1 L/5 L bucket	Formalin, ambient	Fugro	IHM	Microscopy	UKAS	NA	Indefinite

Notes:

Al = Aluminium; As = Arsenic; Ba = Barium; Cd = Cadmium; Cr = Chromium; Cu = Copper
Fe = Iron; Hg = Mercury; Ni = Nickel; Pb = Lead; Se = Selenium; Zn = Zinc
TOC = Total organic carbon
PSD = Particle size distribution
NDIR = Non-dispersive infrared detector
THC = Total hydrocarbon content
IHM = In house method
PAH = Polycyclic aromatic hydrocarbons
NA = Not applicable
GC-FID = Gas chromatography–flame ionisation detection
GC-MS = Gas chromatography-mass spectrometry
ICP-OES = Inductively coupled plasma-optical emission spectroscopy
ICP-MS = Inductively coupled plasma-mass spectrometry
CV-AFS = Cold vapour-atomic fluorescence spectroscopy
UKAS = United Kingdom Accreditation Service

B.2 LABORATORY ANALYSIS - WATERS

B.2.1 Total Suspended Solids (TSS)

Analysis of water samples for TSS content was conducted by Kaizen LAB, Trinidad in accordance with standard method SMEWW 2540 D. Samples were filtered through a glass-fibre filter, which was then dried to a constant weight at 103 °C to 105 °C. The increase in the weight of the filter is representative of the TSS content of the water samples.

B.2.2 Total Organic Carbon (TOC)

Analysis of water samples for TOC content was conducted by Kaizen LAB, Trinidad in accordance with standard method SMEWW 5310 C. Organic carbon is oxidised to CO_2 by persulfate in the presence of heat or ultraviolet light and the CO_2 is measured.

B.2.3 Nutrients (Nitrates, Nitrites and Total Kjeldhal Nitrogen)

Analysis of water samples for nitrates content was conducted by Kaizen LAB, Trinidad in accordance with standard method SMEWW 4500-NO3 – E. Nitrates were obtained by using a spectrophotometric measurement in the UV range at 220 nm and 275 nm.

Analysis of water samples for nitrites content was conducted by Kaizen LAB, Trinidad in accordance with standard method SMEWW 4500-NO2 – B. Nitrites were obtained through formation of a reddish purple azo dye produced at pH 2.0 to 2.5 by coupling diazotised sulfanilamide with N-(1-naphthyl)-ethylenediamine dihydrochloride (NED dihydrochloride).

Analysis of water samples for total Kjeldhal nitrogen (TKN) content was conducted by Kaizen LAB, Trinidad in accordance with standard method SMEWW 4500-N-C. In the presence of H_2SO_4, potassium sulfate (K_2SO_4), and cupric sulfate ($CuSO_4$) catalyst, amino nitrogen of many organic materials is converted to ammonium. Free ammonia also is converted to ammonium. After addition of base, the ammonia is distilled from an alkaline medium and absorbed in boric or sulfuric acid. The ammonia may be determined colorimetrically, by ammonia-selective electrode, or by titration with a standard mineral acid.

B.2.4 Hydrocarbon Analysis

Analysis of water samples for hydrocarbon content was conducted by FGBML using the methods described in Section B1.3, although the following procedure was used in place of B.1.3.2:

B.2.4.1 Liquid-liquid Extraction Procedure

Water samples were thawed, weighed and poured into a 1 litre separating funnel. The empty sample bottle was then weighed. A solution containing an appropriate amount of the following internal standards was added to each sample using a microsyringe.

Aliphatic Standards	Aromatic Standards
Heptamethylnonane	D_8 naphthalene
D_{34} Hexadecane	D_{10} acenaphthene
D_{42} Eicosane	D_{10} phenanthrene
Squalane	D_{10} pyrene
	D_{12} chrysene
	D_{12} perylene

Approximately 50 mL of DCM was used to rinse the sample bottle and this was then poured into the separating funnel containing the sample and internal standard. The separating funnel was shaken thoroughly for approximately 30 seconds and the DCM layer run-off through a 100 mm diameter filter funnel containing a GF-C filter paper approximately half-filed with granular sodium sulphate into a clean 500 mL round-bottomed flask. This was repeated a further two times. The sodium sulphate in the filter funnel was then rinsed three times with approximately 30 mL of DCM.

The contents of the round-bottomed flask were then reduced in volume to approximately 2 mL using a rotary evaporator. The extract was transferred quantitatively into an 8 mL screw top vial, evaporated to approximately 1 mL under a gentle stream of nitrogen and approximately 2 mL of pentane was added to the vials. The clean-up and analysis procedures were then followed as for the sediment samples.

B.2.5 Metals

Analysis of water samples for metals content was conducted by Kaizen LAB, Trinidad in accordance with standard method SMEWW 3030 F, SMEWW 3120 B. Samples were digested on a hot plate with the addition of concentrated nitric acid, then hydrochloric acid and water were added, and the sample was heated prior to adjusting the volume to 100 mL and analysing by ICP-OES.

B.2.6 Sampling and Analysis Requirements – Waters

Analyte	Volume per Sample [mL]	Sample Container	Fixative/Storage	Analysing Lab	Method Code	Method Description	Accreditation	MRV	Holding Time
Al	500	Plastic bottle	Nitric acid, refrigerate	Kaizen LAB	SMEWW 3030 F, 3120 B	ICP-OES	TT labs	50 µg/L	6 months
As								-	
Ba								50 µg/L	
Cd								0.40 µg/L	
Cr								8.0 µg/L	
Cu								8.0 µg/L	
Fe								200 µg/L	
Ni								5.0 µg/L	
Pb								3.0 µg/L	
Se								6.0 µg/L	
Zn								200 µg/L	
Hg								0.100 µg/L	30 days
TOC	2 × 40	Glass vials	Dihydrogen phosphate, refrigerate	Kaizen LAB	SMEWW 5310 C	Persulfate ultraviolet/ heated persulfate oxidation method	TT labs	-	7 days
TSS	1000	Plastic bottle	Refrigerate	Kaizen LAB	SMEWW 2540 D	Filtration, gravimetry (dried at 103 °C to 105 °C)	TT labs	-	7 days
THC	1000	Amber Glass	Freeze	Fugro	IHM	GC-FID	-	10 µg/L	152 days
n-Alkanes					IHM	GC-FID	-	-	
PAH (EPA 16/alkylated)					IHM	GC-MS	-	0.1/1 ng/L	
Spare	1000	Plastic bottle	Freeze	Fugro (spare)	NA	NA	NA	NA	NA

Notes:

Al = Aluminium; As = Arsenic; Ba = Barium; Cd = Cadmium; Cr = Chromium; Cu = Copper
Fe = Iron; Hg = Mercury; Ni = Nickel; Pb = Lead; Se = Selenium; Zn = Zinc
TOC = Total organic carbon
THC = Total hydrocarbon content
IHM = In house method
PAH = Polycyclic aromatic hydrocarbon
NA = Not applicable
GC-FID = Gas chromatography–flame ionisation detection
GC-MS = Gas chromatography-mass spectrometry
ICP-OES = Inductively coupled plasma-optical emission spectroscopy

B.3 STATISTICAL ANALYSIS

B.3.1 Correlations

Depth, crude granulometric data, chemical data and univariate indices of community structure were correlated using Spearman's Rank Correlation Coefficient. This is calculated as follows:

$$\rho = \frac{\sum(x-\overline{x})\,(y-\overline{y})}{\sqrt{\sum(x-\overline{x})^2\sum(y-\overline{y})^2}}$$

Where x and y are ranked vales for each variable.

The resultant test statistic (ρ) will range from -1 to 1, with -1 indicating a very strong negative correlation, 0 no correlation and 1 a very strong positive correlation. Significance levels were assigned from tabulated values for a two-tail test at 5 % and 1 % based on Fowler et al. (2013).

B.3.2 Univariate and Multivariate Analysis of Macrofauna Data

B.3.2.1 Primary Variables and Diversity Indices

A range of primary variables and derived indices were calculated that attempt to quantify the species richness, evenness and a combination of both. The primary variables (number of individuals and species) and diversity indices (Shannon-Wiener diversity, Brillouin's diversity, Simpson's diversity and Pielou's evenness) were calculated for both the samples and the pooled replicates for each station using the PRIMER v6 DIVERSE procedure.

Shannon Wiener Index (H' or more specifically H'Log$_2$)

The Shannon-Wiener index (or Shannon-Wiener information function) is essentially a measure of how difficult it would be to predict correctly the species of the next individual collected from the community under study. It is a measure of uncertainty and was originally developed to assess the information content of codes. Information content is a measure of uncertainty, so that the larger the value of the index, the greater the uncertainty. It is usually expressed as:

$$= -\sum_i P_i \,\mathrm{Log}(P_i)$$

Where pi is the proportion of the ith species. For practical application, the formula can be expanded to:

$$H_s = C\left(\log_{10} N - \frac{1}{N}\sum n_i \log_{10} n_i\right)$$

Where N = total number of individuals
ni = number of individuals of ith species
C = conversion factor $\log_{10} - \log_2$.

Two components of diversity are combined in the Shannon-Wiener index. These are species richness (i.e. numbers of species) and the equitability or evenness of distribution of individuals among the species. A greater number of species increases the index value as does more even distribution of

individuals amongst species. Theoretically, the Shannon-Wiener index should only be used on random samples drawn from a large community in which the total number of species is known. This is, of course, not usually possible and so the use of the index is always a compromise.

Simpsons (1-λ)

Simpson's index of diversity is derived from probability theory. It is simply a measure of the probability of picking two individuals from a community at random that are different species. The index is calculated from:

$$D = 1 - \sum_{i=1}^{s} (p_i)^2$$

Where pi is the proportion of the ith species. An expanded and more practicable formula is:

$$D = 1 - \sum \frac{n_i(n_i - 1)}{N(N-1)}$$

Where ni = number of individuals of ith species
N = total number of individuals.

Simpson's index assigns relatively little weight to rare species, and more weight to the common ones. It ranges in value from 0 (low diversity) to a maximum of (1 to 1/s) where s = the number of species.

Brillouin's Index (Hb)

This index, like that of Shannon-Wiener, is concerned with information content. However, unlike the Shannon-Wiener index, which provides an estimate of the community diversity, Brillouin's index provides the actual diversity of the fully censused sample. It is not a statistical estimate but an actual measurement of the diversity of the sample unit. The formula, displayed below, contains factorials that can involve very large numbers in computation. In the past, this has been a serious drawback to the use of the index by practical ecologists. This is no longer the case with the advent of personal computers capable of high speed calculations.

The formula for Brillouin's index is:

$$H_b = \frac{1}{N} \log_e \frac{N!}{N_1! N_2! \ldots N_s!}$$

Where N = total number of individuals
Ni = number of individuals of the i^{th} species
S = total number of species in the collection.

As the index provides the exact diversity of the sample, it is most appropriate in surveys where it is not possible to define the limits of the population. Since this is nearly always the case when dealing with benthic communities, Brillouin's index has much to commend it in offshore pollution monitoring studies.

Pielou's Equitability (J)

Equitability refers to the evenness with which individuals are distributed amongst species. Equitability is clearly a component of species diversity and certainly enters into diversity indices such as H'Log$_2$, Hb, and λ.

Equitability can be assessed in several ways, the most commonly used approach being to calculate the theoretical diversity for a given species abundance list if all the species were equal in abundance. The equitability of the sample can then be defined as the ratio of the actual diversity to the theoretical maximum.

This is usually done using the Shannon-Wiener index (H'Log$_2$)

If all species are equally represented, then the equation can be written:

$$H'(max) = -S\left(\frac{1}{s} log2 \frac{1}{s}\right) = log_s S$$

The equitability ratio is therefore:

$$J = \frac{H_s}{log_2 S}$$

Where J = equitability measure (Pielou)
H' = calculated Shannon-Wiener diversity
S = total number of species.

Heip (1974) has suggested a modified form of Pielou's J that is essentially the antilog of H' divided by the antilog of H(max). To prevent equitability values at the extreme end of the range becoming nonsensical Heip took the precaution of subtracting 1 from the enumerator and denominator so that his index becomes:

$$Eh = \frac{2^H - 1}{s - 1}$$

Where 2H = the antilog of H'
S = the number of species.

The advantage of this measure is that it appears to provide more realistic equitability values in absolute terms; however, there is a curvilinear relationship between Eh and H' making it difficult to compare ranges of equitability. Although used by Government Laboratories, Heip's measure is not widely used elsewhere.

B.3.2.2 Multivariate Analysis

Macrofauna abundance data was analysed by multivariate techniques using the statistical package PRIMER v6. Approaches followed those outlined in Clarke and Gorley (2006). The main techniques used to interrogate the data are detailed below.

Pre-treatment and Transformations: prior to analysis data typically undergo transformation to down weight the effect of dominant data components in determining inter-sample similarities. These transformations vary in their effect through: no transform; square root (√); fourth root/double square root (√√); logarithmic, and; reduction to presence/absence. At the former end of the spectrum (no transform) all attention is focused on the dominant components of the dataset, and at the latter end (reduction to presence/absence) equal weighting is applied to all components (Clarke and Gorley, 2006). Macrofauna data is generally fourth root transformed for multivariate analysis. However, due to the small numbers of individuals in each taxon, square root transformation was used in this instance as detailed within the report.

Similarity Matrices: a triangular similarity matrix was produced from the square root transformed data, by calculating the similarity between every pair of replicate samples. The Bray-Curtis similarity coefficient was used for macrofaunal data (Bray and Curtis, 1957). This similarity measure is considered the most suitable as it maintains independence of joint absence (i.e. will not infer similarity between samples based on the absence of a certain parameter in them).

Hierarchical Agglomerative Clustering (CLUSTER) and Similarity Profile Testing (SIMPROF): the CLUSTER programme uses the similarity matrix to successively fuse samples into groups and groups into clusters according to their level of similarity. The end point of this process is a single cluster containing all the samples, which is displayed by means of a dendrogram with similarity displayed on one axis and samples on the other. Similarity profile permutation tests (SIMPROF) were also performed, to look for evidence of genuine statistically significant clusters, in samples that are a-priori unstructured (i.e. with no prior statistical design). By combining this significance testing with the CLUSTER function, dendrograms are produced indicating those clusters that are statistically significant.

Correlations with Environmental Variables: if more than one benthic assemblage was present in the macrofaunal data (i.e. there was structuring in the data), attempts were made to match the variation with reported environmental variables. This process can help identify relationships between the physical or chemical environment and the benthic communities present.

† = m/z 276 - anthanthrene/indenopyrenes/benzperylenes
‡ = NPD - naphthalenes, phenanthrenes and dibenzothiophenes (totals)

E.4 DISTRIBUTION OF AROMATIC HYDROCARBONS

The layout of the three-dimensional plots are as follows:

- Naphthalenes (molecular mass 128, 142, 156, 170, 184);
- Phenanthrenes/anthracenes (molecular mass 178, 192, 206, 220);
- Fluoranthenes/pyrenes (molecular mass 202, 216, 230, 244);
- Chrysene/benzanthracenes (molecular mass 228, 242, 256);
- Benzfluoranthenes/benzpyrenes/perylenes (molecular mass 252, 266, 280);
- Anthanthrenes/indenopyrenes/benzoperylenes (molecular mass 276, 290, 304).

E.4.1 Sediment

Concentrations of aromatic hydrocarbons in sediments were too low, hence three-dimensional plots are not presented.
